Specification Requirements of Munitions Material

By F. C. H.

One of the many beneficial results derived from the manufacture of munitions is the greatly increased appreciation, by engineering firms generally, of the benefits to be derived from judicious heat treatment of metals. In the automobile and steel making industries such procedure had been highly developed, but the applications of scientific thermal manipulations to every-day work had been more or less neglected. Future conditions may largely alter this state of affairs, so that heat-treating will ultimately assume its true position.

TO many of those engaged in the manufacture of munitions the reasons for accurate specifications with relation to metallurgy is not apparent. The common principles of heat treatment of carbon and alloy steels and non-ferrous metals are generally understood, yet there are many little points of interest and importance.

Large guns are made up of concentric wire-wound tubes of steel having the following composition:—

Condition of steel	El. limit lbs. per sq. in.	Tensile strength lbs. per sq. in.	Elongation in 2 in.	Carbon	Manganese	Chrome	Vanadium
Soft	35,400	78,800	24%	.40	.80	...	...
Hardened in oil		118,500	14%	...	...	...	...
1450° F. drawn 800	66,900	102,040	....	...	...	...	...
Soft	61,000	83,700	35%	.30	.50	.90	.20
Hardened	99,020	132,000	30%	...	...	...	...
Soft	63,660	103,440	26%	.50	.90	1.00	.20
Hardened	170,000	190,000	15%	...	...	...	...

These tubes are necessarily put under compression so that when the cartridge is exploded, with subsequent stresses, the elastic limit will not be exceeded and a reasonable factor of safety allowed.

The chamber pressure on the 18-pdr., 3 in., 6 in., 8 in., and 9.2 in. guns is from 26,880 lbs. per sq. in. to 33,600 lbs. per sq. in., and on rifles it is a little higher, possibly 45,000 lbs. per sq. in.

On this necessary chamber pressure is based the calculations which determine the requirements of the specifications. In the case of high explosive shells at the moment of explosion of propelling charge, the inertia of shell results in a sudden compressive force being applied through the base and this force tends to bulge the walls of shell which will occur if the shells are soft. For this reason, after high explosive shells are forged they should be stood on end to cool and a reasonable distance apart instead of being piled. This piling of hot shells would cause them to be softened by annealing. As there is no subsequent heat treating for high explosive as compared with shrapnel, defects are not developed as when grinding the latter.

Base plates have a test piece taken across the grain as well as one with the grain. The piece taken across is a check to be sure the material is not piped or seamy, as these defects occur principally at the centre. These plates are subjected to the same strain as the shell and specifications are similar.

Shrapnel Design

The shrapnel shell, while opposing the bursting charge due to its own inertia and being subjected to compressive stress, is also subject to tensile stress, due to the shrapnel bullets inside. In order that these bullets may be thrown forward the shell is designed with a thick wall at the base and this wall gradually tapers off to a thin point near the socket in nose. When the fuse explodes the charge, this thin wall bursts or spreads open, or the fuse threads are stripped. If the steel is too hard the shock of the explosion in the cartridge case will cause fracture with damage to the gun, and if the cartridge case is too hard, due to excessive zinc, permanent deformation will cause it to stick in the gun and prohibit its use over again after being refilled.

While specifications for shell steel have close limits, it should be possible to use steel of higher tensile strength but having good elongation. In this way it would be possible to use almost any analysis, getting the physical properties by heat treatment.

If the steel is hard and brittle, when the shell bursts the pieces break into many small parts, whereas, if the steel is tough, the pieces are larger and the edges are rougher, tending to tear instead of cut, thereby doing more damage.

Cartridge Case Requirements

If the brass cartridge cases vary much in the zinc content from 70 copper, 30 zinc, difficulties will be experienced in manufacture and the product will not permit of being loaded three times as specified.

Formerly, the French military specifications considered uniformity so important that they went so far as to specify where the spelter and copper should come from. The reason for this is doubtless the fact that the analysis must be correct to give a minimum of scrap during manufacture. The great loads to which this material is put during manufacture under 500 and 800-ton presses, for indenting and heading, necessitates punches made of the best of steel, capable of withstanding approximately 160,000 lbs. per sq. in. Carbon steel of about 1.25 per cent. carbon was used for the first two sections, as the punches were built up of water quenched sections, heating to 1475 deg. F. and drawing at 430 deg. F. The remaining portion of punches was .90 to .95 per cent. carbon steel.

In determining the capacity of presses required, crushers of brass were made and tested on a Riehle 100-ton testing machine and from these results the power of presses required was calculated.

The pressures required for operations were:—

Cupping and drawing about	15,000 to 40,000 lbs.
Tapering, 1st operation	8,000 lbs.
Tapering, 2nd operation	20,000 lbs.
Stripping after 1st oper.	3,000 lbs.
Strippin after 2nd oper.	11,000 lbs.
Stripping after heading	16,000 lbs.

Scleroscope Tests

Sclerescope tests were made from day to day on the material, and the results compared with analyses, the result being that only the raw material which came within the scleroscope hardness numbers of 20 and 25, was accepted and readings of either 15 or 30 caused rejections.

A test made on a cartridge case during and after every operation in manufacturing gave:—

Operation	Base	At ¼"	At 2"	At 5"	At 10"
Disc	16				
Cup					
B	20—27	51—55			
A	19—21	21—23			
1st Draw:

2	52—55				
3	48—55				

B = before annealing.
A = after annealing.

It is interesting to note the effect of annealing which is done at 1 200 deg. F. for 30 minutes, and to note how the hardness increases as the thickness of metal decreases.

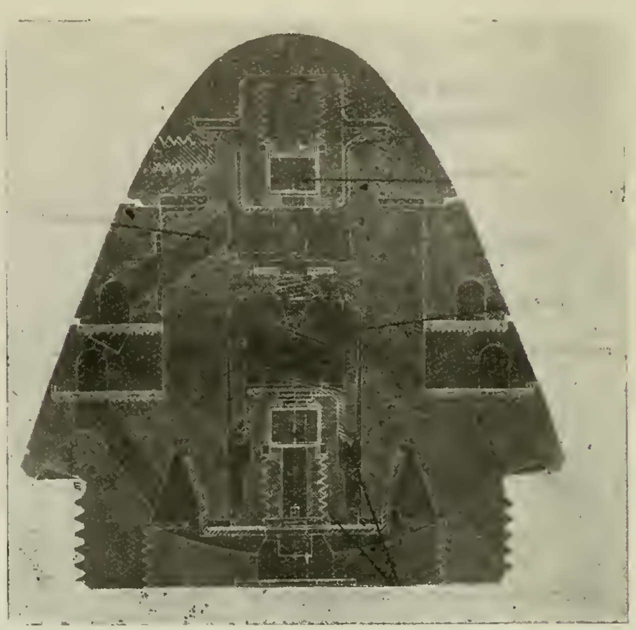
If tensile test pieces are examined after being annealed at a high temperature, the surface is rough, showing the grain is too large and that there are cleavage cracks. Annealing at 750 deg. F. gives enlarged grain, and at 1380 deg. F. the grain size is about at the maximum allowable if the brass is to be of any commercial use.

The following table shows the physical properties for different annealing temperatures:—

Annealing temp. degs. Fahr.	Maximum stress tons per sq. in.	Elongation in 2 In.
As rolled	25.00	15.5
545	28.50	20.0
662	26.20	30.0
932	18.20	54.0
1166	17.00	58.0
1256	16.50	58.0
1382	16.00	63.0
1475	15.00	59.0
1560	15.00	59.0
1650	14.00	53.0
1690	13.00	25.0

If brass is held too long at a temperature above 1,300 deg. F., the metal will be greatly weakened. The most important factor is to anneal at the lowest possible temperature necessary to get the desired results.

The fuse material required is most interesting, as the manufacture and loading of this piece is difficult and exacting. There are several grades of brass, each of which is to be used for specified purposes.



SECTION OF TYPICAL FUSE SHOWING PARTS REFERRED TO

country possesses no advantage over the other two, which permit of an output of approximately 6,000 per day on one automatic machine. The other two methods are simply matters of cost as to which is the cheaper. In all three methods of manufacture the product is afterwards sized with a broach, and the percussion pellet which is also part of this arrangement is given the same treatment.

Metal and Purpose.	Yield lbs. per sq. inch	Breaking Load, lbs. per sq. inch	Elongation in 2 inches and ½ inch dia.	Copper	Zinc	Lead
Delta Metal—Time and percussion, pellets and screw plugs	44,800	67,200	20	64.74	34.11	1.00
Hard Rolled Brass — Stirrup springs	13,440	26,880	10	60.00	38.0	2.0
Class A Metal—Ferrule and setting pin	44,800	67,200	20	70.00	30.00	....
Class B Metal—Rings	26,880	44,800	30	65.00	35.00	....
Class C Metal—Rings (alternative)	13,440	26,880	10	60.00	38.00	2.0
Class G Metal—Percussion pellets (alternative bodies)	17,920	44,800	20	65.00	35.00	....

Pellets and Other Details

The stirrup springs are stampings and hold the time and percussion pellets from arming on the time needle and ferrule respectively. The time pellet should arm at from 125 to 165 lbs. and the percussion from 77 to 99 lbs., while the ferrule arms at from 200 to 300 lbs.

The ferrule must be accurately made to give the correct weight, the analysis of the metal must be right, and the annealing accurately done for that analysis. The annealing, of course, varies as the analysis. If the zinc contents is high the metal will be harder and the temperature proportionately higher. This temperature varies from 890 deg. Fahr. to 1,200 deg. Fahr. and 15 to 20 minutes is allowed in the furnace, after which a water quenching bath is used.

Some manufacturers make these ferrules from brass tubing, some use bar stock, and some use sheet metal; cupping or drawing them out, chucking, cutting off the blind end, boring, putting on a mandrel and turning the outside. The last method is very slow and in this

These pellets are made of hard metal so that they will not deform on the explosion of detonator, thus causing the full force of explosion to be in the desired direction; recently they have been made of inferior metal, as the percussion pellets are reinforced by the ferrule which is in reality a band around it.

Action of Fuse

It may be of interest to know what happens in the fuse when the gun is fired. The time pellet by reason of its own weight straightens out the stirrup spring and the detonator is pierced, the flash igniting the powder in the flash hole in stem and carrying it to the powder train in top ring. The ferrule due to its own inertia straightens out the percussion stirrup spring and arms itself on the percussion pellet, the whole arrangement being kept from creeping onto the percussion needle by a spiral spring. When the shell strikes, if the time element has not previously taken effect, the resistance of the spiral spring is overcome and the detonator is punctured, the flash extending through the pellet plug, which has a hole bored through it, and the base charge ignited, causing the shell to explode.

On the American fuses there are no ferrules or stirrup springs. The time pellet has a groove left where the pellet plug is screwed in, and into this groove is placed a split brass ring, which must slip over the edge of groove before the detonator can be pierced. The percussion element has a small pendulum, which is thrown out by centrifugal force due to shell rotating; as this pendulum swings out, a needle, which is formed on the other end, is lined up to strike a detonator when the resistance of two small spiral springs is overcome.

Arming Resistance of Pellets

The theory on which the arming resistance is figured is on the maximum allowable chamber pressure and the weight of ferrules.

Suppose:—

The area of gun equals 8½ sq. inches; the chamber pressure equals about 15 tons.

Thrust of explosion in this area is against an 18-lb. shell.

If we find the amount of resistance of each grain of weight and multiply by weight of ferrule, we know what the set back of ferrule will be. The same argument holds good for the time pellet. Some specifications allow for a factor of safety to insure of the parts working, others do not.

The fuse bodies are cast in permanent moulds or chills, which give a closer, finer grained casting, free from gas holes and the increase in breaking strength is from 10 to 15 per cent., with 20 to 25 per cent. increase in elongation.

Sometimes the bodies are cast in green sand moulds and sized afterwards in a die, which gives a similar result to die casting, this alternative, however, being practiced with less success.

CANADIAN IRON AND STEEL PRODUCTION

THE Dominion Department of Mines has received from the producers a record of the production of pig iron and of steel ingots and castings during the first eleven months of the year 1916, which, together with the estimates for December, show a probable production of pig iron in Canada during the twelve months ending December 31, 1916, of 1,171,727 short tons (1,046,185 gross tons), and a probable production of steel ingots and direct steel castings of 1,454,124 short tons (1,298,325 gross tons), of which 1,423,485 short tons were steel ingots, and 30,639 short tons were direct castings.

The production of pig iron in 1915 was 913,775 short tons and of steel ingots and castings 1,020,896 short tons, showing an increase in the production of pig iron in 1916 of about 28 per cent., and an increase in production of steel ingots and castings of over 42 per cent. The 1916 production is greater than that of any previous year, the second largest production of pig iron having been 1,128,967 short tons in 1913, and of steel ingots and castings 1,168,993 short tons, also in 1913. The production in 1916 during the first six months and monthly during the last six months was as follows in gross tons:—

6 months ending	Pig Iron	Steel Ingots	Direct Castings	Total
June	501,577	577,999	11,715	589,714
July	82,154	101,178	2,284	103,462
Aug.	78,450	108,889	2,299	111,188
Sept.	91,736	116,828	2,524	119,352
Oct.	101,436	126,577	2,924	129,601
Nov., partly est.	95,237	119,468	2,745	122,213
Dec. est.	95,300	119,930	2,865	122,795
Six mons. end. Dec.	544,313	692,970	15,641	708,611
Twelve mons. end. Dec.	1,046,185	1,270,969	27,356	1,298,325

Of the total production of steel ingots and castings in 1916, about 43,790 short tons (39,098 gross tons) were made in electric furnaces. In 1915 only 61 short tons were reported as having been made in electric furnaces.

PRESSURE OIL FILM LUBRICATION*

By H. T. Newbigin, A.M.I.C.E.

THE primitive form of journal bearing is merely a hole bored in the frame of a machine in which a shaft revolves, and the primitive thrust bearing is only a collar or shoulder on a shaft to prevent it moving endways. These fulfil their function satisfactorily for many purposes, but as the rubbing speed increases, either due to an increase in the shaft diameter or an increase in the speed of its rotation, or both, it becomes necessary to devote more attention to the design of these machine parts, apart altogether from the effect of a reduction in friction on the efficiency of the machine as a whole.

Without lubrication a bearing will not run without excessive wear, and without artificial cooling no bearing with oil lubrication will run continuously if the temperature rises above 150 deg. F., because at about this temperature most oils begin to carbonize. The efficiency of a bearing must, therefore, be such that the temperature due to the heat generated by its friction, minus that dissipated by radiation and conduction, does not exceed this figure. In order to reduce the friction between two rubbing surfaces it is necessary to put something between them, and bearings may be classified into those in which this is a hard material such as steel balls or rollers, or a viscous substance like oil or grease.

*Part I. of a paper read recently before the British Association.

Ball and Roller Bearings

The first class does not consist merely in introducing balls or rollers between the relatively moving surfaces in the primitive forms of journal and thrust bearings, they are highly specialized machine parts designed to utilize to the greatest advantage the rolling action of balls or rollers in reducing friction, and their design is evolved from a study of this action. On the other hand (except in the cases to which reference will be made later), the second class consists merely in applying a lubricant to the primitive forms, or to some slight modification thereof. They are not designed to utilize the action of the lubricant on any principle, the lubricant is merely added to the primitive forms because it has been found to make them work better. Ball and roller bearings have attained to a remarkable degree of perfection, and they are admirably suited for bearings in which the loads to be carried are comparatively light, or in which the motion is intermittent, but they are not suited to carry heavy continuous loads, especially at high speeds.

In ball bearings the steel balls make point contact with hardened steel races, and the balls tend to flatten at the point of contact. Under excessive continuous loads this slight deformation of the balls causes their outer surface to shell off, the chips get under the other balls, and ultimately destroy the construction of the bearing. The life of the balls is limited, frequent renewals are necessary, and to effect these renewals it is essential to dismantle the bearing.

In roller bearings the rollers make (or are supposed to make) line contact with the housing and with the shaft. Although they are able to carry heavy loads, it is very difficult to maintain correct alignment, and any slewing of the rollers sets up a heavy end thrust against the cage in which they work. Furthermore, as the rollers bear directly on the shaft, the constant rolling action tends to laminate the surface and so wear it away. In roller thrust bearings it is necessary to make the rollers conical, and as they therefore have a heavy radial thrust this type of bearing is not much used.

The great advantage of both ball and roller bearings is their low starting friction; for this reason they are especially suitable for intermittently moving machinery, but in continuously running machinery, where a low starting friction is of less importance than a low running one, it is obviously a great advantage to have the rubbing surfaces separated by something more easily replaceable than either balls or rollers, especially if it is something that can be continuously replaced without stopping the machine, and the more so if it is also capable of being used in high-speed bearings as a medium for carrying away the heat generated by friction from the actual surface of its origin.

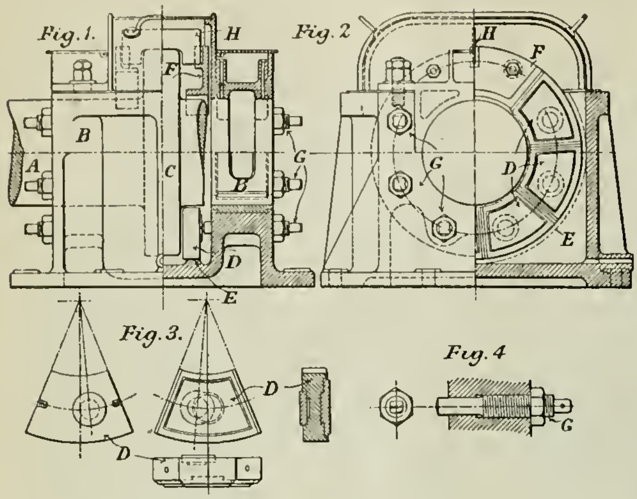
It is with the second class of bearings—those in which the surfaces are separated by a fluid such as oil in the case of high-speed and grease in the case of slow-speed bearings—that this paper is more immediately concerned. The use of a lubricant for the purpose of reducing friction is very old, but the study of its action, and more especially the manufacture of bearings designed to utilize this action to the best advantage, is quite modern.

Lubricant Action

The action of a lubricant is twofold: it first of all alters the nature of the rubbing surfaces, thereby reducing friction (and this is the commonly accepted justification for its use), but under favorable conditions it goes much further than this and automatically generates a high-pressure oil film between the surfaces, entirely eliminating metallic contact and thereby enormously reducing the friction. This is what is now called "pressure oil film lubrication." It occurs to a limited extent in most journal bearings, but does not occur in ordinary collar-thrust bearings.

The phenomenon of pressure oil film lubrication was first noticed by the late Beauchamp Tower during the course of a series of tests he made in conjunction with the Institute of Mechanical Engineers in 1883 and 1885. He found, while experimenting with a journal bearing, that under certain conditions the rotation of the shaft was capable of dragging the oil adhering to it in between the surfaces to such an extent as to force the surfaces apart with a high-pressure oil film, and that the highest pressure in this oil film was about twice the average pressure. He also found that the highest pressure was on the longitudinal centre line of the brass and a little forward of the sectional centre line in the direction of rotation, and that from this point the pressure fell to zero around the edges of the brass. A bearing under these conditions runs with very much less friction than under any other, and will carry a much higher load.

Following on Tower's experiments, the late Professor Osborne Reynolds, F.R.S., in a paper read before the Royal Society in 1886 on "The Theory of Lubrication," showed that the friction under the circumstances was merely that due to the viscous flow of the oil, and he showed how, by calculation based on the theory of viscous flow, a pressure curve



MICHELL THRUST BEARING DETAIL.

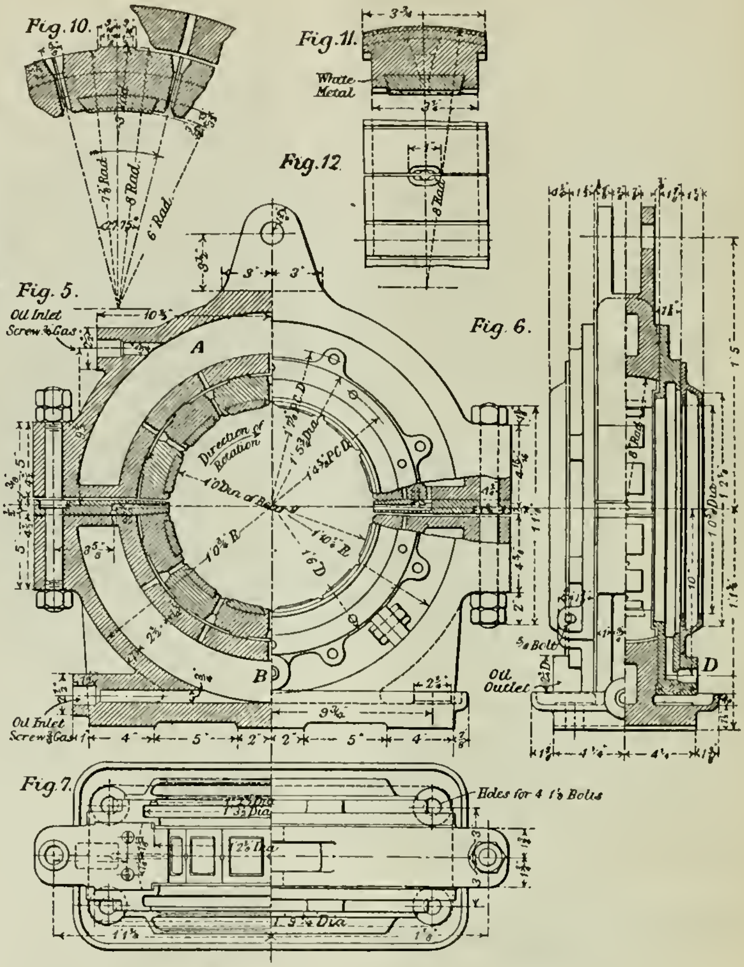
may be obtained which closely approximates to that obtained experimentally by Tower.

In his theory Reynolds made the assumption that the length of the bearing, i.e., the dimension at right angles to the direction of motion, was infinite, and as this is never the case in practice, his theory was of little practical value and it did not lead to any alteration in the construction of bearings. From the practical point of view the most important things that he showed were:—

Firstly—That in order to obtain a pressure oil film between lubricated surfaces the surfaces must have a slight inclination to each other, with the opening at which the oil enters greater than that at which it leaves. Or, in other words, that the oil film must be wedge-shaped.

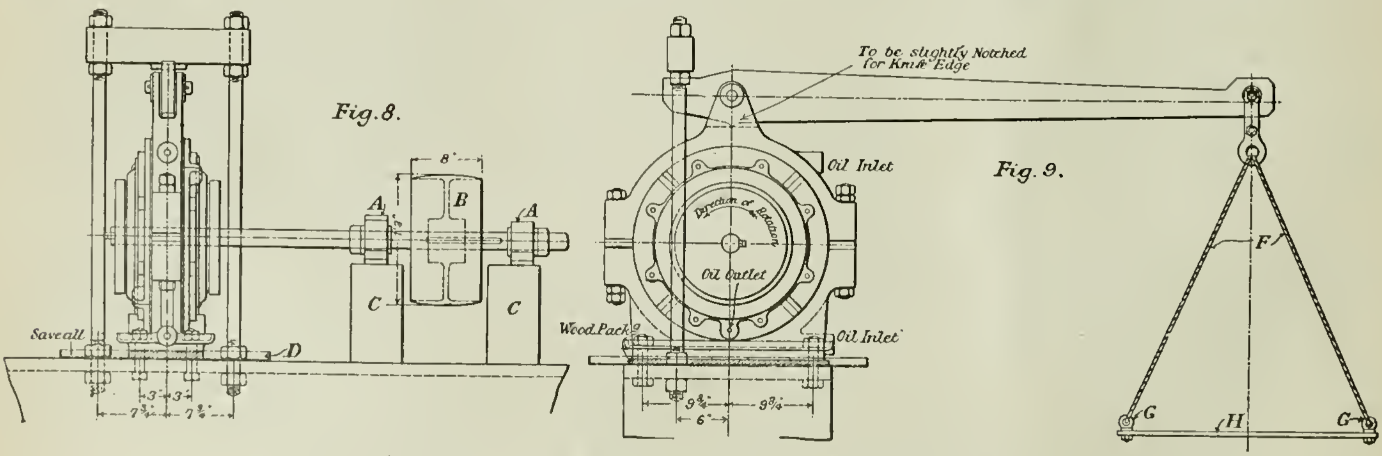
Secondly—That in the case of a journal bearing the wedge form of the oil film occurs naturally, due to a slight shifting of the centre of the shaft in relation to the centre of the brass.

Thirdly—That such a wedge-shaped oil film cannot occur in a collar-thrust bearing; hence their inefficiency and low carrying capacity.



DETAIL OF MICHELL JOURNAL BEARING AS TESTED.

It was left to an Australian engineer and mathematician, A. G. M. Michell, of Melbourne, not only to complete Reynolds's theory, but also to show how its teaching can be applied in practice, to the vast improvement of both thrust and journal bearings.



TESTING EQUIPMENT OF MICHELL JOURNAL BEARING.

In a paper published in "Zeitschrift für Mathematik und Physik" (unfortunately a German publication) in 1905, on "The Lubrication of Plane Surfaces," he gave the complete mathematical solution of Reynolds's theory as applied to plane rectangular surfaces. On the assumption that the thickness of the oil film at the entering edge is twice as great as at the leaving edge, he showed how lines of equal pressure within the film can be plotted and how the centre of resultant pressure can be determined for plane rectangular surfaces of varying proportional cross dimensions. He also demonstrated practically that a rectangular block pivoted at its point of resultant pressure will automatically assume an angle to an opposing lubricated surface, depending on the speed of rubbing, viscosity of the oil and pressure. On this principle he founded his now well-known thrust bearing.

The result of Mr. Michell's work has been to enable lubricated thrust and journal bearings to be designed with the principles of oil film lubrication as a basis, in the same way as ball and roller bearings are designed with the ball or roller as a unit, and as distinguished from the mere application of oil to the primitive forms of these bearings. The essential feature of the Michell bearings is the sub-division of the stationary surface into a number of blocks or pads, each pivoted at its back, and so free to assume a slight angle with its contacting surface. Bearings designed on this principle differ radically from the primitive forms of journal and thrust bearings, but the results obtained in practice have fully justified the change.

Thrust Bearing Comparisons

Taking the case of the thrust bearing first, the Michell thrust bearing differs from the older type in having only one collar, the multiplicity of collars in the older type having been necessitated by the low carrying capacity of parallel rubbing surfaces, as distinguished from the high carrying capacity of those in which the fixed surface is sub-divided and made free to assume the angle to the opposing collar necessary for the formation of oil pressure within the film.

The importance of efficiency in machinery is not merely a question of economy of power or fuel, it also controls the practicability of a design, and the design of bearings is an example of this For example, in the design of a large multicollar thrust bearing (which is merely an elaboration of the primitive form) the problem the designer has to solve is governed by the efficiency of this form. He has given a shaft of a certain diameter, revolving at a certain speed, and which has to withstand a certain thrust. The resistance to turning will be about 0.03 of that thrust, and the greatest load that the bearing surfaces will carry with safety is about 50 lb. per square inch.

Low Coefficient of Friction Essential

In order to bring the pressure down to this figure, he may either use a few collars of large diameter or a number of collars of small diameter. If he does the former, he increases the radius at which the friction acts, and so the power absorbed and the heat generated, and if he does the latter it becomes increasingly difficult to maintain an equal distribution of the load among the collars, especially under the variations of expansion due to the heat generated when the bearing is at work. Furthermore, whatever compromise he makes, there comes a point beyond which the size, load and speed cannot be increased because, owing to the high coefficient of friction, the heat is generated more quickly than it can be dissipated by radiation and conduction, even with the aid of water cooling.

This point was reached in the case of the thrust bearings in geared turbine-driven vessels, and partly because the bearings were found to be less able to withstand thrust under the uniform turning movement given by this type of engine than under the varying turning movement given by reciprocating engines. It therefore became necessary to find a form of thrust bearing in which the coefficient of friction is lower than that in the primitive type.

Michell Thrust Bearing Details

The Michell thrust bearing, which goes to the root of the matter and is designed from the point of view of the action of the lubricant in automatically generating a pressure oil film between the surfaces, has formed a complete solution of the difficulty. It has a coefficient of friction of about 0.0015 as against 0.03, and carries 200-300 lb. per square inch with a much greater factor of safety than the primitive form has at 50 lb.

The sub-division of the fixed surfaces into a number of segmental tipping blocks or pads is the essential feature of all thrust bearings made on this principle, but there are many variations in the design of the housing and method of carrying the tipping blocks, depending on the particular use to which the bearing is to be put.

Figs. 1 and 2 show sectional side and end views of one form in which marine thrust blocks are made. The shaft A is supported in two journal bearings B, one on each side of a single collar C, which bears against two series of segmental pivoted blocks D, arranged in the form of two inverted horse-shoes, the one for "ahead" and the other for "astern" thrust. The blocks D—each of which is pivoted, somewhat behind its centre, on the ends of the screws G—rest on two ledges E, concentric with the shaft. They are prevented from rotating with the shaft by means of the stops F, by removing which they may be taken out without disturbing the adjustment of the screws G or lifting the shaft. Figs. 3 and 4 show a detail of one of the blocks D, and of its screw G.

The body of the housing forms an oil well in which the collar revolves, and a scraper H is provided to scrape off the oil brought up by the rotating collar for the purpose of lubricating the upper blocks. This type is self-contained as regards lubrication, and in the case of large sizes, or those running at a high speed, the body of the bearing is water-jacketed. The friction is about one-twenty-fifth of that in the multicollar type.

Steam Turbine Thrust Bearings

In the case of the thrust bearings in steam turbines the type adopted is somewhat different. The blocks are symmetrically disposed around the faces of the collar, and each series is mounted on a ring partly spherical on one face, the convex surfaces of which are outward and rest on correspondingly spherical seats for the purpose of automatically distributing the load among the blocks. The blocks are mounted on the faces of the rings next the two sides of the collar against which they pivot, either along radial lines or on rounded pins.

This type is entirely enclosed, and is supplied with an oil circulation by means of an independent pump. The oil passes through an oil cooler on its course, thereby removing the heat generated by friction from the actual surface of its origin. The mean rubbing speed sometimes exceeds 100 ft. per second. Slow speed bearings are made on the same principle, with grease lubrication.

Upwards of 800 Michell thrust bearings are now running in Great Britain alone, in sizes varying from 1 to 15 in. diameter of shaft, and larger sizes are in the course of construction. The use of them is rapidly becoming the standard practice in steam turbine work. The same principle is now being applied to journal bearings.

Journal Bearing Comparisons

In lubricated journal bearings of the primitive type (as already stated) the phenomenon of pressure oil film lubrication occurs naturally, due to the slight shifting of the centre of the shaft in relation to the centre of the brass, but its occurrence is much less marked in the case of bearings of large diameters, probably owing to the greater oil clearance that is necessary in large sizes and to the extreme thinness of the oil film. For example, a journal bearing of 2 or 3 in. in diameter will run satisfactorily under a pressure of 300 to 400 lb. pressure per square inch, but it is not found advisable to load large bearings above 100 lb. even with a forced oil circulation.

The pressure oil film only occurs along a narrow strip in the primitive type, and the remaining surface merely forms a brake on the rotation of the shaft. So that the designer is again restricted and can only reduce the pressure to the limit found safe in practice by increasing the length of the bearing. By sub-dividing the circumferential surface into a number of segments, each of which is pivoted at its back and thereby free to form an independent pressure oil film between its rubbing surface and the shaft, the number of the pressure oil films can be increased, so that the full projected surface of the bearings becomes effective for carrying load, and the brake surface is eliminated. The friction is thus reduced, the load-carrying capacity increased, and the bearing shortened.

Michell Journal Bearing Tests

A series of tests has recently been run on a Michell journal bearing by Cammell, Laird & Co., Birkenhead. Figs. 5, 6 and 7 show details of the experimental bearing, and Figs. 8 and 9 the method of testing it. As will be seen from Fig. 5, the bearing surface is divided into 12 segments, each of which is pivoted on a rib at its back, so that it is free to lift at its leading edge to allow the necessary wedge-shaped oil film to form. These segments are shown in detail by Figs. 10 and 11. The faces of the segments or blocks are lined with white metal, each surface being 2 in. square, giving 48 sq. in. of rubbing surface, the equivalent projected area of each half of the bearings is 16½ sq. in.

In addition to the segments being free to tilt, the seat on which they rest is partly spherical, thereby making the bearing also a swivelling one. A circulation of oil was passed through the bearing, entering it between each pair of blocks from the chambers A and B, and escaping at D. The bearing was driven by means of an electric motor, and the ammeter and voltmeter readings recorded. Each run was continued until the temperatures of the oil were also recorded, together with the weight of the oil passing, and the revolutions per minute. The load was applied by adding weights to the scale pan H, shown in Fig. 9, the leverage being 11 to 1.

The annexed table gives the results observed, together with the friction calculated from the heat taken up by the oil. The friction is that for the two halves of the bearing pressed together. To get the coefficient of friction these figures require to be divided by twice the load.

Canadian Machine-Tool Industry on Sound Basis

For many years the engineering industry of this country was dependent on outside sources for the great proportion of its machine tools. The past two years have witnessed a wonderful development of tool building capacity, in specialized as well as staple lines and a resumption of ordinary manufacturing activity will find many firms capable of supplying suitable equipment.

THE impetus given to machine tool building in Canada by the demand for munitions equipment in the first eighteen months of the war has continued without abatement. Many of the improvised machines did excellent work but the constant cry for greater output along with the increased size of shells made, has resulted in the continued improvement of machine tool design, as well as the frequent appearance of new types of tools, accessories and processes.

A prominent example of specialized munition machine production is the Holden-Morgan Co., Toronto, who have developed their line of thread millers till it includes machines for 12 in. shells and over, two other sizes taking up to 6 in. dia. and 7 in. to 9.2 dia. respectively. Included in their product are a thread miller for base adapter plugs larger than 6 in.; a combined turning, facing and threading machine for gas check plugs up to 6 in.; a socket thread miller for outside threads on fuse sockets, nose pieces, etc.; a mechanical plug wrench for H. E. shells up to 6 in.; a nose slotting machine for milling simultaneously the three riveting notches on British 4.5 in. shells.

Cutting-off Machines

The cutting-off of billets and forgings has kept tool builders in this line very active, John H. Hall & Sons, Brantford, Ont., putting out a complete line up to their No. 12 machine which has a capacity of 13 in. through the chuck and drum. No. 6 machine which cuts from 4.5 in. to 6 in. is made up with double or triple tool blocks, permitting one, two or three cuts off stock at one chucking. The oxygen cutting torch has been successfully applied to the cutting of billet bars, the Carter Welding Co., having developed a machine of the multiple type equipped with four Davis-Bournonville cutting torches. In direct opposition to this is the Schoop Metal Spraying Process operated by the Metals Coating Co., Montreal, by which it is possible to deposit steel upon steel with a high degree of integral perfection.

Interest attaches to the output of the Canadian Boomer & Boschert Press Co., Montreal, their efforts in the hydraulic machinery line having resulted in their building forging presses up to 350 tons capacity; 5¼ in. x 14 in. vertical triplex power pumps, capacity 100 gals. per min. at 1,500 lbs. per sq. in.; 18 in. x 15 ft. accumulators, capacity 180 gals. per stroke, at 1,500 lbs. per sq. in., these items being the largest machines of their particular type at present built in this country. A special continuous operation press for gun cotton manufacture has also been developed by them.

Capacity production on standard designs of quick change type engine lathes has been the feature of the year's operations by the Canada Machinery Corporation, Galt, Ont., sizes from 14 in. to 26 in. inclusive having been largely installed in ammunition plants throughout the country. Their Hespeler plant has also done considerable business in

special machines for making munition boxes. The John Bertram & Sons Co., Dundas, Ont., have supplied a considerable proportion of the tools for larger shell production, many of these being standard designs, which, with slight additional equipment were well suited for sustained effort of a strenuous nature. Tread millers for the smaller size shells were produced to a large extent and the manufacture of special munitions fixtures for typhoid tools also received much attention.

The Tool Steel Feature

The manner in which machine tools have been pressed has only been possible by the existence of materials possessing the necessary cutting qualities, and it is a matter of peculiar interest that the two most efficient materials for this purpose are now being produced within the Dominion. Armstrong, Whitworth Ltd., are the pioneer manufacturers of high-speed steel, their works at Longueuil, Que., having produced this material for some time with very satisfactory results. A contrast is also offered in this direction by the proven success of Stellite, which is made at Deloro, Ont., and distributed by the Canadian B. K. Morton Co. Characterized as it is by a total absence of iron in its composition, this material possesses an extreme hardness at all temperatures up to red heat which enables it to cut at phenomenally high speeds without loss of temper, retaining its edge for long periods.

Canadian built milling machines are now on the market, the Ford-Smith Machine Co., Hamilton, having gotten out a design of plain miller to meet the demand for this type of machine.

Shell Nosing Equipment

In munitions equipment a feature of the year has been the use of power and steam hammers for closing in the nose of medium size shells, the accuracy obtainable, through the use of the special equipment developed, enabling a later machining operation to be dispensed with. Greater uniformity in the quality of materials, improved forging and heat treatment have largely eliminated machining troubles so that grinding work is very much reduced, and in the larger shells is unnecessary. Specialization in munitions tools has been very marked, one outstanding instance being where all operations are performed on machines with hydraulic feeds, chucks and handling equipment with remarkable success. The milling of three slots in mark VII shells has resulted in special machines being placed on the market a simple type with three direct belt-driven cutters being marketed by H.W. Petrie, Ltd. For parties desiring to use existing machines a simple attachment has been built by Marsh & Henthorn, Belleville, Ont., which can be used on a milling machine, drill press or small lathe. It mills the slots in rotation and while not so rapid as the three cutter machines, its simplicity and adaptability render it a useful device.

Special band turning lathes have continued to be a feature of the output of Jenckes Machine Co., Sherbrooke, Que., being made in sizes up to 14 in., and tooled for foreign shells as well. General equipment has received considerable attention from several firms, Sheldons, Galt, Ont., having manufactured such lines as special tanks, resin boilers, bullet loading apparatus, electric painting machines and exhaust and ventilating fans, these being largely required for fumes from furnace rooms, lunch rooms, etc., in shell plants.

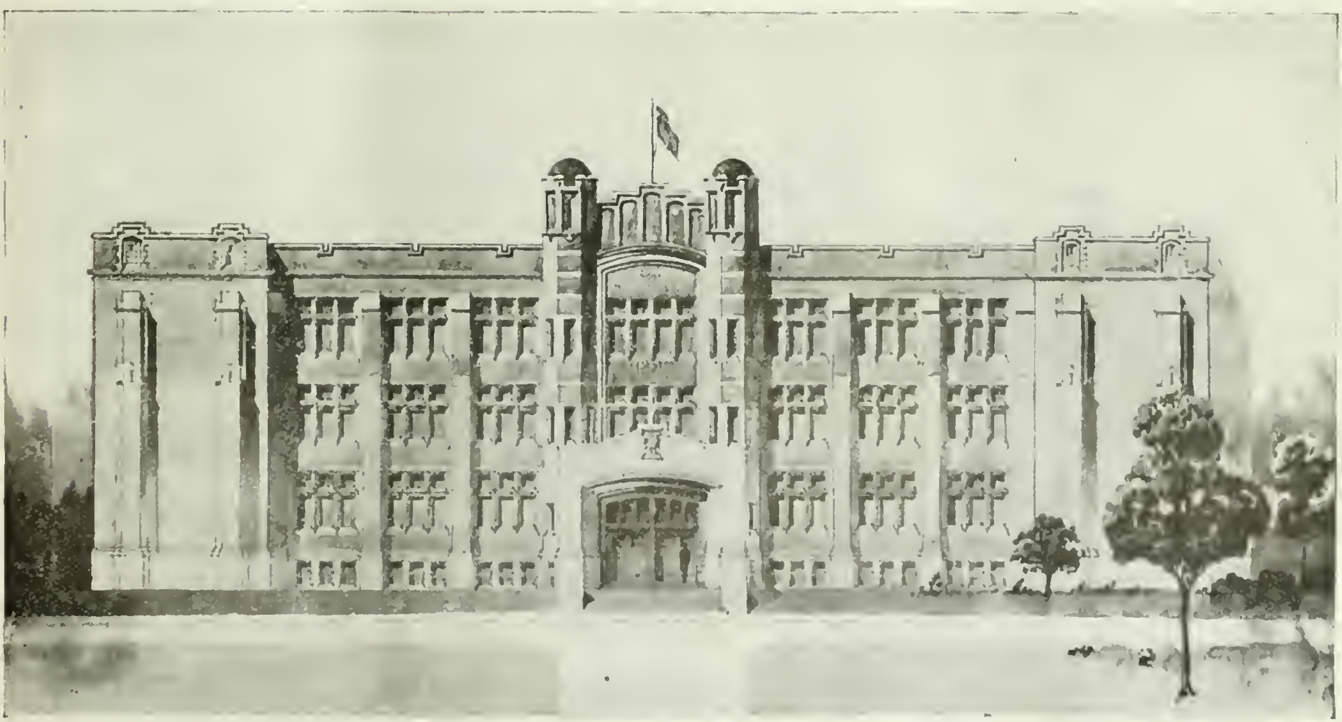
Ball-bearing transmission apparatus has received growing recognition as a standard item of factory equipment, the Chapman Double Ball Bearing Co., Toronto, having supplied the entire transmission material for the new Dominion Arsenal at Lindsay. Transfer trucks are also being more generally adopted, the Universal truck as built by this firm having been improved in several respects as a result of extended use in many lines of industry.

HIGH SCHOOL OF COMMERCE, TORONTO

By R. H. Eldon, B.A.*

PREVIOUS to the autumn of 1904, commercial clases were conducted in each of the city High Schools. then three in number. In September, 1904, the Board of Education transferred the commercial classes from the three city High Schools to the Toronto Technical School. The eight commercial classes in this school formed the Department of Commerce and Finance, and in September, 1911, this department was organized into the High School of Commerce, and located temporarily on Bathurst Street, and later, September, 1913, on Clinton Street.

*Principal, High School of Commerce, Toronto.



FRONT ELEVATION, NEW CENTRAL HIGH SCHOOL OF COMMERCE, TORONTO, ONT.

A suitable site and recreation grounds were purchased and a very fine up-to-date building has been erected thereon. The site is situated a little north of College; it extends from Roxton Road to Shaw Street, and is between three and four acres in extent. The new building was opened last September, and is being equipped with the most modern appliances for demonstrating business methods and systems of accounting, and for presenting the various aspects of business life.

Accommodation

The following accommodation is provided:—Twenty-one class rooms; one business practice room; one business practice office; two typewriting rooms; two study-of-material laboratories; two lecture rooms; one commercial art room; one commercial museum; two emergency rooms; one library and reading room; and an auditorium capable of seating one thousand persons. The basement, which is well above ground, contains assembling rooms, recreation rooms, bicycle rooms, and toilet rooms—on the west side for boys and on the east side for girls. There is also a students' supply room and a large cafeteria, located centrally between the boys' and girls' quarters, and thus readily accessible to both. When completed, the total cost of the building, equipment and site will be about half a million dollars.

Evening classes were opened in the Central School in October, 1912, while branch evening schools were opened as follows:—The eastern branch in Queen Alexandra School in 1912, the western branch in the Annette Street School in 1913, and the northern branch in North Toronto High School in 1914.

The school and its branches are under the management of an advisory commercial committee, appointed by the Board of Education. This committee consists of four persons selected from the Board of Education and four from the business men of the city.

Purpose of School

The purpose of the school is to give a general High School education, together with such a training in business theory and practice that students, besides being generally well informed, will be able to adapt themselves to the needs of any business with which they may become identified. Besides inculcating such requisites as punctuality, regularity, faithfulness, courtesy, and industry, and besides giving a knowledge of business routine, the purpose is to give such a training, such an outlook on life, as will develop prompt and accurate judgments—the cultivation of the intellectual equally with the mechanical, which is essential to leadership in the business world.

Particularly in the general business course are students given a knowledge of the facts of nature and of the economics of the world around them. With this broader outlook they are inspired with an ambition which will enable them to advance more rapidly to superior positions in the business world, and to the more intelligently cope with the problems which will meet them in a business career. Thus, while the cultural side is not neglected, the aim is to make all the subjects serve the special vocational purpose for which this class of school exists, namely, a preparation for business.

Regular Courses

The following are the various courses offered to students. It is not intended, however, that these courses shall turn out thoroughly trained business men and women, but rather students so trained that they may readily adapt themselves to and master the details of any business with which they may become connected:

1—Accountancy Course.—This extends over three years, and is intended to fit students to become bookkeepers, accountants, etc.

2—Stenography Course.—This also extends over three years, and is intended to meet the needs of students looking forward to positions as stenographers, amanuenses, secretaries, etc.

3—Secretarial Course.—This is a broader course and extends over four years. It prepares students not only for stenography and general office work, but more particularly for the work of the private secretary.

4—Salesmanship Course.—This is also a broader course and extends over four years. Its purpose is to prepare students not only for general office work, but for positions that will eventually lead to salesmanship both in the warehouse and on the road.

5—General Business Course.—This course, like the two preceding, is a broader one, and extends over four years. Its purpose is not only to give a general High School education, but to assist those entering business with a view of succeeding to some of the more responsible positions, eventually becoming travellers, buyers, managers, partners, or proprietors.

The evening classes provide theoretical and practical instruction for both young men and young women—for clerks, salesmen, stenographers, bookkeepers, artisans, and others who desire to improve themselves in any of the following subjects:—Bookkeeping, business practice, business law, civics, penmanship, stenography, typewriting, spelling, business English, business arithmetic, rapid calculation, mensuration, algebra, study of material, salesmanship, French, German, or any other commercial subject for which there may be a sufficient demand.

The enrolment for the present season in the Central School is 550 for the day classes, and over 1,500 in the evening classes. The enrolment in the branch evening classes is over 350, making a total of over 2,400.

TORONTO UNION STATION

SUFFICIENT progress has been made with the building of the new Union Station to enable a good idea to be formed of its ultimate extent and form and also its influence on the immediately adjacent district. The structure is being erected by the Toronto Terminals Railway Co., composed of three representatives each, of both the Canadian Pacific Railway and the Grand Trunk Railway.

The various officials responsible for the design and construction have devoted their entire energies and abilities to the object of the undertaking, viz., the provision of a perfect passenger terminal irrespective of cost. The area covered is rectangular in shape, the train tracks passing through the southern half, while the passenger accommodation and office building occupy the northern half. The travelling public is handled entirely in the central portion of the building, post office requirements being arranged in the extreme eastern section, and railway offices provided in the extreme western section.

Two main public entrances enable travelers to pass directly into the ticket lobby 250 ft. long, by 84 ft. wide, by 86 ft. high, which is in direct communication with the various conveniences of modern travel: — Parcels, baggage, lunch, telephone, telegraph, rest and smoke rooms. Extending southward from the lobby and situated below the train tracks is the train concourse, 100 ft. wide, by 230 ft. long, from which stairs lead up to the platforms above, these latter being 20 ft. wide.

Baggage is handled through special trucking subways which eliminate the necessity of trucking amongst passengers on the platform. Special provision has been made for handling light and heavy traffic, as under the latter conditions exit traffic is entirely separated from incoming. Very complete arrangements are to be provided in the way of immigration quarters, these being such that complete separation is effected from the ordinary passenger traffic, special accommodation such as kitchen, laundry, and offices being made. Hospital arrangements also are provided, these being in the west block.

St. Lawrence Closed.—With the arrival of the steamers Montcalm, Rouville and Lord Strathcona at Quebec on Dec. 25 navigation was officially closed on the St. Lawrence between there and the sea. This is one day later than last year.

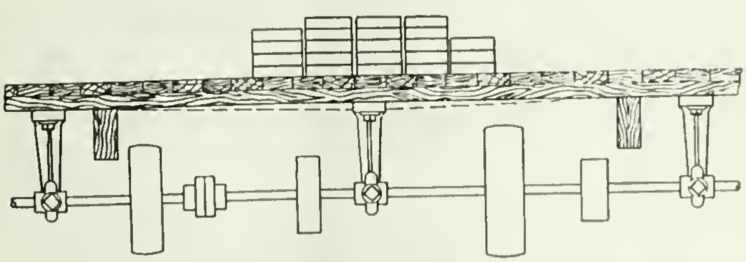
LINE SHAFT TROUBLE

By J. H. R.

AMONG the many problems that power users are required to solve, those arising from transmission are probably the most numerous. No one application is identical with another, and local conditions make it imperative that each installation, or the solution of trouble arising from unknown causes, must be dealt with on its own merits. Previous experience is often a guide to the difficulties of the moment, but unless a careful study is also made of the local surroundings, it is not to be expected that the results obtained will be entirely satisfactory.

Some time ago, a certain shop was confronted with considerable trouble on a portion of a line shaft, that taxed the patience of the foreman for quite a long period. The accompanying line drawing illustrates roughly the arrangement of the hangers and shafting. As shown, the center hanger came about midway between two joists, the next on either side being located on the other side of the joists. On numerous occasions, the center bearing would become heated and trouble would develop in the shaft coupling. This experience was not continuous, only taking place at irregular intervals. Several efforts were made to remedy the trouble by lining up the shafting, which on each occasion required, adjustment. However, the source was discovered one day when the foreman was on the floor above. He noticed a large pile of cased tin in the center of the floor and the vibration that developed when another case was added to the pile. Upon investigation, it was found that this lot of tin, weighing over two tons, was placed directly over the hanger which was giving trouble. Being an old building, this floor was not intended to support any



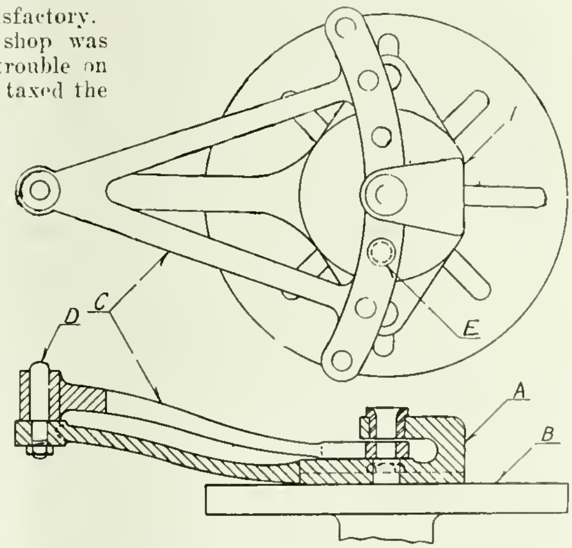
LINE SHAFT TROUBLE

great weight upon a small area. The result in this instance was a depression in the floor, which, being transmitted to the hanger, caused a bend in the shaft and hence originated the trouble. The removal of the cases to a more suitable position and the exercise of care in the subsequent location of all heavy loads effected an immediate and permanent cure.

JIG FOR DRILLING SEXTANTS

By R. Hamilton.

THE sketch herewith shows a very useful jig for drilling the holes in the outer rim of the sextant C. The jig A, which is secured to the drill table has a protruding arm, the outer end carrying the central pin D, upon which the centre



JIG FOR DRILLING SEXTANTS

hole of the casting is placed. After the first hole has been drilled, the position for the adjacent hole is determined by locating the pin E through the first hole and into the base of the jig. The spacing of the holes can be varied by the position of the pin hole in the jig base.

WHY THEY FAILED

By D. A. H.

TOM and Fred had been, respectively, salesman and designer for the R-Printing Press Co. In their spare moments they had developed an automatic press of exceeding merit, had had several built on contract, and their success being so marked had given up their positions and started a shop of their own. In a year's time they had failed and sold out at a sacrifice to a rival who wanted to suppress the competition.

The cause of their failure was the same as that of many other men who leave big concerns and start a small one of their own. Not only were both good business men but they were alive and up to date, thoroughly familiar with the most efficient shop and office practice and knew the value of a dollar expended for men or materials. It had been decided at the beginning that quality should be first in everything, and at the end, no man could say that any work had ever been done that wasn't correct from a mechanical, or clerical or business standpoint. Overconfidence and lack of small shop perspective were the rocks on which they split.

An Ambitious Start

With $50,000 capital Tom and Fred put a tenth of it in the plant (and a like amount on mortgage) which could have been leased for $70 per month. Another $2,000 went for alterations to make shipping and receiving goods at the cars an efficient process though the output was to be but two presses a month.

In common with most printing press work, many spur gears were required, also studs and shafts. Planing side frames and drilling them was one of the particular jobs. Good tools were bought, among them a turret lathe, a screw machine, a gear cutter, and a multiple drill, having in mind the operations just mentioned.

It will be seen that the work was carried on in the most approved way. But a man trained in the atmosphere of a scanty purse could hardly have thought in such an "approved" way. He would have bought stock gears, redesigning if necessary so he could have used them. Result—saved a few thousands for the future and got along without turret lathe and gear cutter to say nothing of patterns and small tools.

Overlooked Economies

Pattern cost was higher than need have been. Levers and arms and braces were designed in such a manner that while they showed real designing and made a finished looking product, they took a great deal of time to make the patterns with no decrease in the amount of machine work required and no corresponding increase in efficiency in the assembled machine over what the same parts would have shown if made a little heavier and plainer at a greater saving in pattern cost. Cores were used where it would have been cheaper to have done machine work on the single pieces required. Patterns and castings were used when a blacksmith-made forging would have done.

Complete blueprints were made of everything down to the little "wrinkle" this fussy customer wanted, operation sheets were made out, time cards and stock cards were made as complete as the most ardent systematizer could have wished. But, the money spent for all the unnecessary equipment, the time spent (or rather lost) in carrying out the intricacies of an elaborate system, and the losses connected with being up-to-date and mechanically correct—all caused the failure of Tom and Fred. "Surely this was a blow for the advocates of efficient methods," said one. No, it only shows that we must discriminate and that what is meat for one is poison for another. If the money spent as mentioned had been conserved as working capital, the purchase of certain machinery delayed until it could have been made out of earnings, and for system, a hustling foreman or two with a good memory substituted the shop would have prospered, no doubt.

Hustle Best System

That "hustle" can be substituted for a great deal of system and unwisely spent money, can be proven by a consideration of an actual instance in a certain city where there were two shops each employing twenty men and each doing a line of manufacturing and "helping out" with job work and special machinery. In the first there was an office force of seven people besides a foreman who had nothing to do but direct the men and interpret blueprints. Even a repair job was the subject of cards innumerable, drawings, etc. by the office force and if it was a hurry job it could finally reach the shop in half an hour. That was the ideal shop "they knew how to do things," people said—and if a man went there with work he felt that he was being looked after; an engineer leaned back in his chair and duly considered point after point, draftsmen plotted them down, clerks made out cards—modern, scientific, efficient!

In the other shop there was "no system." The men put their time down on slips that the boss collected once a week; the boss did all the clerical work himself, though the business was fully as extensive as in the ideal shop. Then there was Sandy, the Scotch foreman, just the boss and Sandy and twenty men. If you took a breakdown job in there Sandy looked it over and planned the work as he looked and had one or more men at work on it in five minutes. If it was an engineering problem—a device or design or an estimate—Sandy pondered over it as he made his rounds and during a spare half hour sat down and sketched it out. In the end Sandy gave you just as good as the other people but got little credit for it—the uninitiated said, "there's no class to that shop, no science"; but somehow the shop paid dividends and the ideal one did not and in the long run it got the trade—and grew to a size that could profitably adopt a system.

THE VALUE OF BRAINS

By A. L. Haas.

A WELL-KNOWN publicist, when speaking recently, remarked that the war had taught manufacturers a lot of valuable lessons. As one who had seen the thing from the inside, nothing had impressed him more than this—that the British employer and workman had not in the past placed the proper value they ought upon the service of brains.

In connection with the procedure of local tribunals, employers have appealed on behalf of men stated to be absolutely indispensable in business of considerable value, whose salaries were meagre and out of all proportion to their alleged value. Indeed, the most interesting question which has come to light in regard to compulsory military service has been just this one matter of responsibility and pay. Coupling the two things together, one is driven to conclude that admitted capacity and adequate reward therefor are more or less divorced, and that the conditions are not confined to any one country, but are universal.

Conditions Known

The facts are notorious and perfectly well known. It has hitherto been well-nigh impossible to find the door of opportunity open to simple mental power, uncoupled with other qualifications of a material order. Stupidity on the part of a workman is readily cited, but extraordinary intelligence when displayed goes unrecognized, the evident fear being that he might ask for advancement. Only those devoid of influence, who engineered themselves into superior positions, know exactly the struggle needed, the disappointments and delays inseparable from any material progress in their career. The competition among trained and capable men for posts at relatively low salaries proves the supply to be adequate. It is stuff and rubbish to point to lack of competition at the top of the scale. To state that the upper rungs of the ladder carry few men has no bearing on the point at issue; it merely points to the fact that very big jobs are relatively few.

The first question asked an applicant is what previous experience he has had in the precise post applied for! Where the candidate for honors is to commence to qualify seems never to trouble his interlocutor in this connection. Previous experience is admittedly valuable, but in too many instances points to a limited and routine experience—sometimes an unsatisfactory man given a good testimonial as a salve for virtual dismissal who, on the ground of former experience, gets the post. Previous experience is of less moment than capacity for extension, power of development and other factors few people can assess. Very few men adequately trained in a more general field with proper credentials fail to develop under responsibility. Few are the firms, having sufficient faith in their own organization and belief in their own work as a ground for experience, who promote their own men. Reasons of discipline are cited if the question as to why an outsider was imported for responsible control is asked. Many a concern tied to a term agreement with a man in a responsible position bit their finger ends the major portion of the term after the new man's incapacity is revealed. Subsequently to cut the impasse a first-class testimonial is handed out, and the incompetent is passed along elsewhere to repeat the performance. The feature of finding the right man already in employment is that a term agreement would not be needed, and from the employer's point of view no excessive salary need be paid. Hence both parties have greater freedom of action and each have less to lose.

Concerning the Mainspring

When judging between firm and firm, it is not easy sometimes to find who is the actual brain counting most in the economy of its organization. Sometimes it is one director, occasionally the chief draughtsman; or, again, some man rated no higher than a simple foreman may be the greatest force animating the whole. In spite of investigation sometimes no one can be held to be the man filling the important post of the power behind the throne. If a competitive business survives, it is obvious there is merit somewhere; it may rest entirely with the commercial side—more than one firm has been literally built upon the work of a single salesman. The remainder of the organization are often routine tied, devoid of initiative, or of any organization. For considerable success a combination of circumstances not very usual is needed. The mentality, width of vision and training are taken for granted, but unless the possessor also finds opportunity to develop or scope for energy in a direction which suits his temperament and fits his peculiar abilities he can never realize himself or rise to the height of his powers.

Every case whereby ability is penalized is a national loss. More might be done to discover talent.

Success Defeats Success

Sometimes when a man is extremely successful in one direction, the treatment meted out is similar too often to that of a workman becoming unduly expert on a single job. He is kept repeating his prowess in a circle of small magnitude. A man, successful in a limited field, deserves a better fate; if acute, he speedily realizes that the surest way to constrict opportunity is to be too expert. Actually, his reward should be fuller opportunity, bigger responsibility, and the chance of greater scope. The man finds it necessary to go elsewhere almost unwillingly, to the detriment of his original firm, who lose services they can ill-afford to lose could they only hold him. In too many instances a word of encouragement and promise to consider his claim to advancement when opportunity occurs would keep him satisfied.

We are told to place proper value on the service of brains; they are a reasonably cheap commodity, in view of facts now coming to light. The mentality normally expected in the engineering trades would stagger some outside professional men could they be made to realize the requirements expected for the salary paid. The responsibility which rests upon the man in control of 1,000 men is less in amount, but not in intensity, than that of a military chief or ruler of a country. His mistakes may perchance be less appalling, but his perplexities are certainly not less than those of more public, and consequently more realized careers.

CUTTING DIAMETRAL PITCH WORMS

Herbert's Monthly.

IT may well happen that a firm doing the necessary gear cutting for its own specialties requires to make a worm reduction gear for some accurate job, but wishes to reduce expense and time by doing the cutting in the shop, hobbing the wheel, and cutting the worm thread in the lathe. This operation will necessitate a worm of exactly similar dimensions to the hob, and will be a comparatively easy proposition if the hob be of circular pitch proportions. As, however, the modern method of gear selection utilises the advantages of the diametral pitch system, the majority of the hobs used will be of this type; and much confusion will ensue if a diametral pitch worm is sent to the turnery to be cut.

Various methods may be tried. One usual in the shop is to take the nearest circular pitch in inches, and calculate the usual ratio of Drivers to Driven to this point of accuracy. For instance, 1.05-in. may be used for 3 D.P. (1.0472-in.). This method gives fair results when the error in lead is negligible, but, in most cases, the difference between the worm lead cut and the real lead is considerable, and results in large frictional losses, and low efficiency in the finished product.

A second method sometimes used is to substitute for circular pitch the constant "pi" divided by the diametral pitch, and calculate the requisite change wheels, assuming the value of "pi" as 22/7. This value is, however, only approximate after all, and with large leads may result in serious errors, again producing low efficiency, due to frictional losses. A more accurate method is, therefore, needed.

That here suggested assumes a similar calculation, but depends for its accuracy upon a more careful selection of the value of "pi". This value has been known for a few hundred years in the mathematical world, but seems to be neglected by engineers. The value is simple to remember, viz., 355/13= 3.1415929, and is accurate to one in 10,000,000, and can, therefore, be taken as practically exact.

The standard rule for screw-cutting is:

$$\frac{\text{Drivers}}{\text{Driven}} = \frac{\text{Lead to be cut}}{\text{Lead of lead screw}}$$

The lead of the worm to be cut is however:—

$$L = \frac{\text{"pi"}}{\text{D.P.}} \times \text{No. of threads,}$$

$$= \frac{5 \times 71}{113} \times \frac{\text{N.}}{\text{D.P.}}, \text{ therefore}$$

$$\frac{\text{Drivers}}{\text{Driven}} = \frac{71}{113} \times \frac{5 \times \text{No. of starts}}{\text{D.P.} \times \text{Lead of lead screw}}$$

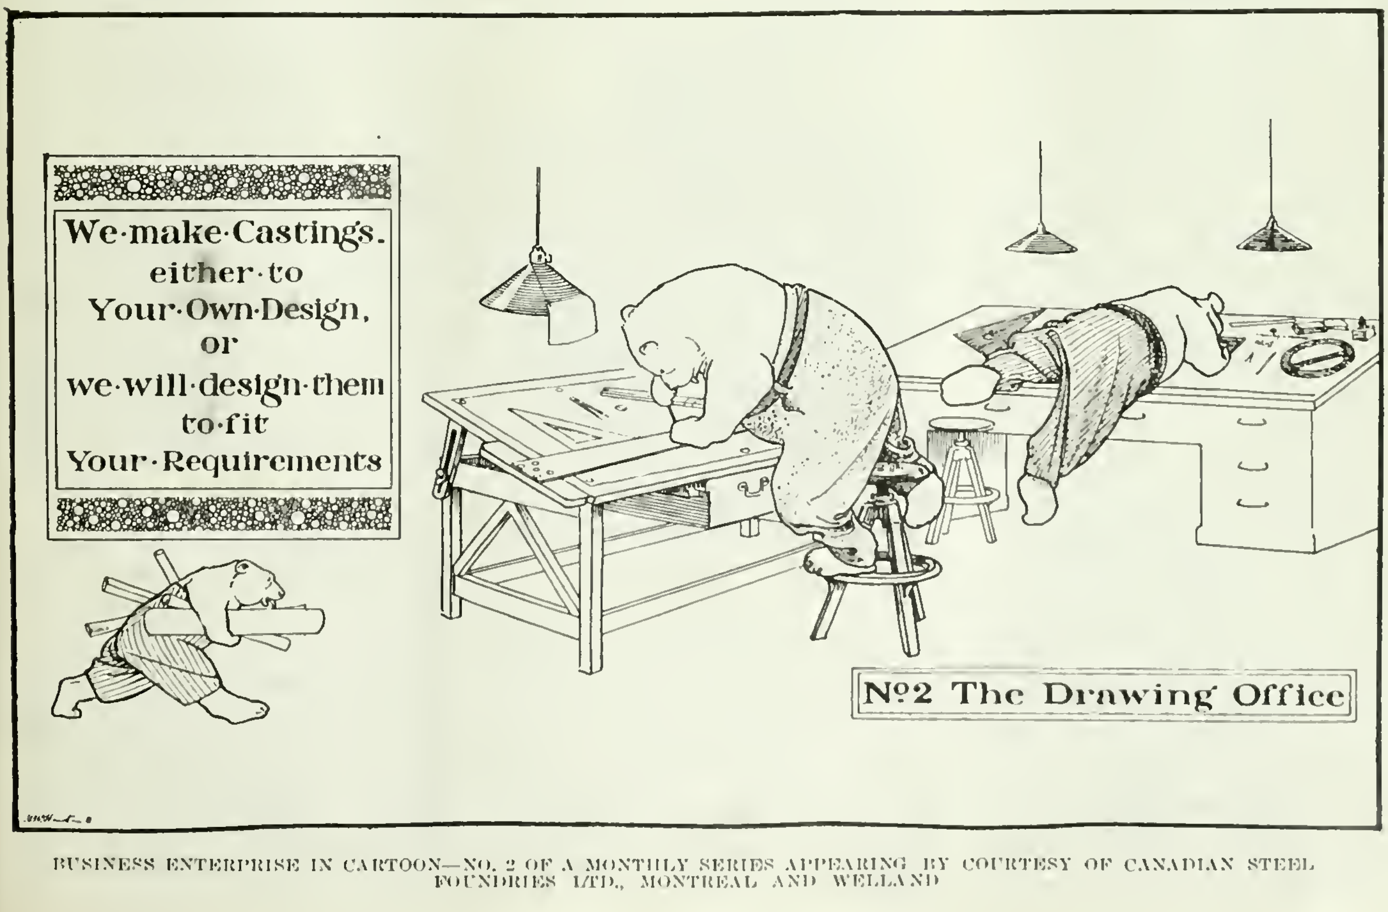
Hence for the small outlay necessary in providing the master gears of 71 and 113—the cutting of which can be done in the shop, we can cut any given diametral pitch worm, and pitch and number of starts, provided the lathe proportions are sufficient to stand the strain. Take, for example, a 5 D.P. worm, 3 threads ½-in. lead screw:—

$$\frac{\text{Drivers}}{\text{Driven}} = \frac{71}{113} \times \frac{5}{5} \times \frac{3}{\frac{1}{2}}$$

$$= \frac{71}{113} \times \frac{120}{20}$$

The resulting gears show that the strain on the lathe will be heavy, but with care it can be done, and the saving will be considerable.

For the ordinary shop, high carbon steel—say .40 or .50 per cent. carbon, will be sufficient, if highly polished on the threads; but if mild steel, case-hardened and finally ground on the threads, be used, care must be taken to have the same ratios on the grinder as on the lathe, or the advantages of the accurate cutting will be lost.



BUSINESS ENTERPRISE IN CARTOON—NO. 2 OF A MONTHLY SERIES APPEARING BY COURTESY OF CANADIAN STEEL FOUNDRIES LTD., MONTREAL AND WELLAND

As this value of "pi" is far beyond the limits of commercial accuracy, almost perfect engagement should ensue, and a maximum efficiency obtained for the spiral angle taken.

Appendix

This value of "pi" may be obtained by the use of the continued fractions method, assuming "pi" = 3.1416.

```
"pi" = 3+ .1416
   1416) 10000 (7
          9912
          ----
           88) 1416 (16
               1408
               ----
                  8) 88 (11
                     88
                     --
```

$$\text{Therefore "pi"} = 3 + \cfrac{1}{7 + \cfrac{1}{16 + \cfrac{1}{11}}}$$

Or, evaluating:—

$$\text{"pi"} = 3\tfrac{1}{7},\ 3\tfrac{16}{113} \text{ or } 3.1416.$$

The first value $3\ 1\text{-}7$ is the usual one adopted. The second $3\frac{16}{113}$ or $\frac{355}{113}$ is the one employed above. The third is the value we commenced with.—Herbert's Monthly.

BUILDING TRADES ACTIVITY THROUGHOUT THE DOMINION

THE building trades through their varying activity form a generally accepted barometer of trade conditions throughout the country. Much of the present year's activities are directly due to war-stimulated trade, but it is of interest to note that much of the Western business in the past year, and projects for next year are based on generally prosperous conditions and are not dependent on specialized industrial activity of a possibly temporary nature.

Galt, Ont.

This has been a record year for building operations in Galt, the total expenditure on new buildings being expected to reach a quarter of a million dollars, or at least $100,000 ahead of last year. Up to November 30 the permits totalled the satisfactory figure of $227,795, compared with $140,249 for last year.

Kingston, Ont.

A decrease of $22,009 is reported in the value of building permits issued up to end of November, 1916, the total value being $181,451. Much will depend on the war as to whether the situation assumes a more favorable outlook for next year.

Lethbridge, Alta.

Fifty-four building permits of a value of $97,290, were issued to the end of Nov., 1916, the year's building being very light due largely to scarcity of labor; should this feature improve, an increase of building is expected next year in view of satisfactory harvest conditions.

London, Ont.

Up to Dec. 11 the total number of permits issued for 1916 numbered 1,017, with a value of $912,385.

Montreal, Que.

A decrease of 175 in the number, and $435,807 in the value of building permits for eleven months ending Nov. 30 is reported, the 1916 figures being 1,800 permits of a value of $5,005,464.

New Westminster, B.C.

New buildings to the value of $53,000 and repairs to the value of $33,000 make up the total of $86,000 value of building operations during the year. Despite the present dulness improved conditions are looked for in the spring.

Regina, Sask.

Building permits numbering 108, of a value of $219,875 represent the ordinary business to Nov. 30, this being exclusive of the Imperial Oil Co. plant, which has cost $1,500,000 to date, with further increases likely during the coming year. General prospects for 1917 are very good.

St. Catharines, Ont.

An increase of 43 per cent. over 1915 is shown in the value of building permits issued, having a value of $637,570. Permanent factory buildings and workmen's homes form a large proportion of the year's operations, the demand for dwellings of this class being expected to increase still further next year.

Saskatoon, Sask.

A large increase in building activity is shown in the value of permits issued during the past year, numbering 108 and valued at $144,550, about 70 per cent. of this being new buildings. Many projects held up during recent years are expected to materialize next year as a result of improved general conditions throughout the West.

Sherbrooke, Que.

Building permits for the past year amount to $367,950, the building trades having been very busy. Much work is planned for next year and the outlook is considered good.

Stratford, Ont.

A slight decrease from last year, shown in the value of this year's building permits, $186,504, is accounted for by the presence of several big contracts last year, the general business being about equal. The coming year is expected to be more active than the past.

Toronto, Ont.

Building permits numbering 3,690, of a value of $6,452,823 were issued up to Nov. 30, an increase of $497,797 in value and a decrease of 495 in number. The total amount of the year is expected to approach the ten million mark, which would exceed last year by 50 per cent. Business for next year is expected to continue good.

Vancouver, B.C.

Building permits issued for first 11 months of 1916 totalled 384, of a value of $2,126,524. The estimated total value for the year is $2,375,000, showing a substantial increase over 1915. The outlook for 1917 is very favorable.

Welland, Ont.

Although 184 building permits were issued up to Nov. 30, of a value of $191,362 and showing an increase of 11½ per. cent. over 1915, the value is still 65 per cent. below that of 1913. A steadily increasing demand for small houses exists, this and factory additions being promising features of the coming year.

Westmount, Que.

The total number of building permits issued during the year was 114 valued at $546,660, 78 of these being for new buildings principally private residences and garages valued at $512,815.

Windsor, Ont.

Building permits numbering 550 were issued for eleven months ending Nov. 30, totalling $1,420,930 in value, an increase of $826,660 over the same period of last year. Prospects for 1917 are considered good.

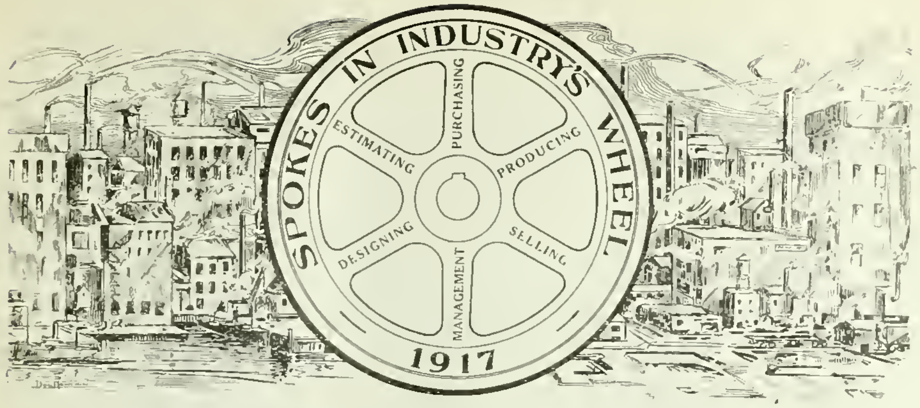
CANADIAN POWER PRODUCTION

THE generation of electricity in Canada, and its division as between domestic and export business, is dealt with in the report of the Inland Revenue Department, issued December 22. It is of especial interest because of the discussion as to exportation of electrical energy.

The Canadian Niagara Co., figuring on the basis of kilowatt hours, produced 400,521,090 units for export, and 11,178,910 for use in Canada. The Electric Development Co. exported 34,652,000, and produced for use in Canada 395,346,500 units. Other companies divided their production as follows:

	Export	Domestic
Ontario Power Co.	199,135,160	616,834,440
Ontario and Minn.	13,144,070	11,789,534
Cedar Rapids Co.	358,753,000	56,031,000
Sherbrooke Power Co.	230,820	8,605,200
Maine & N.B. Co.	3,077,893	242,437
Western Canada Co.,	11,937,700	60,468,020
B. C. Electric	330,626,680	470,689

Bonus to Employees.—The directors of the Canada Steamship Lines have set aside a sum of $50,000 for the purpose of adding an acceptable bonus to the Christmas salary of all its permanent employees throughout the country. This is the first time such a generous Christmas fund has been provided for the employees of the company, and, in fact, the first time that such a fund has been provided at all. That it should come now is indicative of the cordial relations which have grown up among all sections of the company's services in late years.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

THOMAS BAIRD REID

IN Canadian machine tool circles, and particularly in the triple connection of maker, dealer and user, it may be said that there lives, moves, and has its being, no more widely known a personality than Thomas Baird Reid, Hanager of the Machine Tool Department, A. R. Williams Machinery Co., Toronto, Montreal, etc. Machine tool manufacture in a specialised sense has not yet achieved in Canada the degree of prominence so evident in the United States, hence the necessity in many instances, even in normal times, to resort to the latter to meet both our metal and wood working plant requirements. Needless to say, Mr. Reid has figured largely in business transactions arising therefrom, with the result that he is to all intents and purposes as well-known across the border as he is here, and his sterling qualities are no less highly appreciated.

Tom Reid, as he is best known in the machinery business, was born at St. George, Brant County, Province of Ontario, on October 3, 1882, of parents who had come from the "hame and haunts o' Rabbie Burns," a circumstance that doubtless accounts for his inbred, and "automatic" winsomeness in the pursuit of his calling. He was educated in St. George public school and in Brantford High School, matriculating from the latter at the age of seventeen.

Following an apprenticeship with the Waterous Engine Works Co., Brantford, Ont., he went to the United States in 1901, spending some four years there at work in machine tool and locomotive building shops in several American cities where these products are turned out high in grade and large in quantity. Returning to Canada in 1905, he joined the sales staff of the Canadian Fairbanks-Morse Co., leaving them however, about a year later to become machinery salesman with the A. R. Williams Co. With the passing of 1916, a service of over ten years in the latter employ falls to be recorded for Tom, the last seven being in the capacity of manager of the Machine Tool Department.

As might be expected from his Ayrshire extraction, Mr. Reid is Presbyterian in Religion and Liberal in Politics. He is, however, thoroughly Canadian in sport, having been in his younger days at Brantford a member of the Dufferin Rifles, inside home player on the lacrosse team, centre half-back on the Y.M.C.A. Senior Football Team, and the hero of many basket-ball encounters as well. He is an enthusiastic motorist and bowler, the latter as a member of the Parkdale Lawn Bowling Club, Toronto.

THOMAS BAIRD REID.

Mrs. Reid was Miss. Edna Sawtell, youngest daughter of John R. Sawtell, Toronto, the wedding taking place in 1907. The family residence is 70 Beatty Avenue, Toronto.

Since the outbreak of the war and the inauguration of munitions manufacture in Canada, Mr. Reid has investigated and directed the purchase, as well as conducted the sales of machinery running into several millions of dollars in value; in addition, he has personally engineered and equipped something over fifty complete metal-working plants in Canada and three of large production capacity in the United States. Included in the foregoing are to be found such plants as those of the Ford Motor Co., Ford, Ont., Transcona Shell Co., Winnipeg, Man.; Canadian Tube and Iron Co., Montreal, Que., Metal Drawing Co., St. Catharines, Ont., Wilford Engineering Co., Lindsay, Ont.; Holden-Morgan Co., Toronto, Ont.; Framingham Machine Co., Framingham, Mass.; Woonsocket Machine & Press Co., Woonsocket, R. I., etc.

A specially noteworthy factor in Mr. Reid's work during the past two years and one that has been of the greatest material aid to him in the investigation, purchase and sale of munitions equipment on behalf of his firm and its clients respectively, was that of the practical shop training he received during his apprenticeship with the Waterous Engine Works Co., at Brantford, and later in the States. This will perhaps be better and more fully appreciated when we state that, from his ideas and developed designs, quite an imposing member of special machines and special tools for munitions and other services have been manufactured for and sold exclusively by his firm, the A. R. Williams Co.

Tom Reid, like a host of other men prominent in the machine tool and allied fields attributes much of his success to having been a close and constant reader of trade and technical publications, recognising these as indispensable channels of up-to-date information covering machine design and operation, readily available and at low cost with which to supplement both home and technical school studies. Having proved their value, he is therefore, qualified to express a decided and worth-while opinion. "Mechanics—young and old," he says, should subscribe to, read and study, trade and technical journals bearing both directly and indirectly on their work, as only by so doing can they be kept fully posted in the latest developments in new equipment, and the evolution of production methods and devices relative to greater quantity and higher quality output."

From time to time statements appear in the press to the effect that when the history of the war comes to be written, or the story printed of what some one man or some body of men have done or are doing in some department of its many-sided activities, we will be mightily surprised with the accomplishment record. No one is prepared to doubt such predictions, generally speaking, however, in the case of Tom Reid's work on behalf of shell making in Canada, there is no need to wait for the historian at a post-war date, neither is there lacking right now the accomplishment record, for our machine shops over the whole wide Dominion express it in shell and shell part output, irrespective of size and type. Although having much reason to be justly proud of his munitions machinery installation achievement, it may be said without fear of contradiction that Tom still takes the same size hat, and in saying so, we say much.

Canadian Machinery takes this opportunity of wishing him a Bright and Prosperous New Year alike in his home and in his business.

INDUSTRIAL DEVELOPMENT OF HAMILTON, ONT., DURING 1916

FROM the accompanying data, it will be noted that Hamilton, Ont., has, during the past year, quite maintained its reputation both for attracting new factories within its borders and making it worth while for those already established branching out to wider scope activities. Six new factories were located during 1916 as follows:—Perkins Glue Co., Lansdale, Pa.; Stanley Steel Co., New Britain, Conn.; Watkins Medical Co., Winona, Minn.; Turner, Day & Woolworth, Louisville, Ky.; Ontario Yarn Co.; Hamilton Steel Wheel Co. Seventy-one new factories and additions were erected during 1916, of a total value of $994,446. Those of $5,000 or over follow:—

FACTORY.	PROJECT	COST	MANUFACTURE
Steel Company of Canada	Additions	$259,696	Munitions
Zimmerman Mfg. Co.	"	26,000	Knit goods, underwear
Mercury Mills Co.	New factory	125,000	Hosiery
T. Eaton Co.	Additions	11,000	Knit underwear
Canadian Cartridge Co.	"	73,000	Munitions
Tallman Brass Co.	"	16,200	Brass goods
Dominion Steel Foundries	"	70,000	Munitions
Dom. Power & Transmission Co.	New steam plant	200,000	Auxiliary steam plant
Standard Underground Cable Co.	Addition	25,000	Cables, telephone, telegraph wires
Chipman, Holton Co.	New factory	15,000	Hosiery
Brown, Boggs Co.	Rebuilding	11,000	Had a fire
Hamilton Steel Wheel	1st unit	8,000	Steel car wheels
Stanley Steel Co.	New factory	14,000	Cold rolled sheet steel
Grasselli Chemical Co.	Addition	48,000	Chemicals
National Steel Car	"	9,000	Munitions
Appleford Counter Check Book Co.	"	7,500	Counter check books
Dominion Sheet Metal Co.	"	6,000	Galvanized sheets
Hamilton Bridge Works	"	7,500	Structural steel
Can. Steel & Wire Co.	"	5,500	Wire fence
Frost Wire Fence Co.	"	5,000	Wire fence
Union Drawn Steel Co.	"	5,000	Drawn steel shafting
United Gas & Fuel Co.	"	5,000	Water gas plant
Cummer-Dowswell Co.	"	16,000	Washing machines
Canadian Cotton Co.	"	6,000	Textiles
Proctor & Gamble Co.	"	5,000	Soap
Victor Saw Works	"	6,000	Hack saws
Bell Thread Co.	"	5,000	Cotton thread
Can. Shovel and Tool Co.	"	6,000	Shovels
Burlington Steel Co.	"	5,000	Steel shapes and angles
Can. Hart Wheels Co.	"	7,000	Grinding wheels

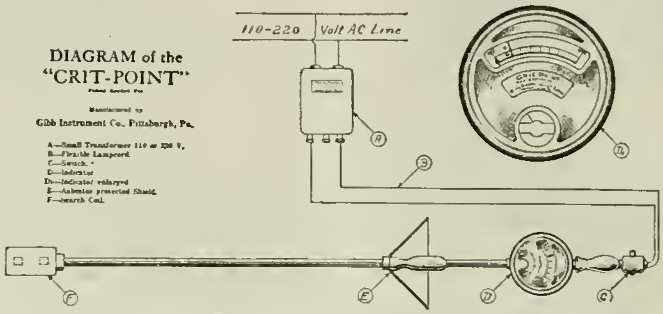
MAGNETIC INDICATOR FOR CRITICAL TEMPERATURES

THE fact that steel loses its magnetic properties on attaining the critical temperature forms the basis on which has been designed the "Crit-Point," an instrument which infallibly indicates the instant when a body of steel has attained the decalescent or hardening point.

In heat treating installations of the usual type, entire reliance is frequently placed on the permanent accuracy of the pyrometer, which is subject to variation through deterioration of the thermo-elements; the element of time demands consideration so that the steel may assume a uniform condition at the required temperature; the personal factor appears in determining whether the two foregoing conditions have yielded the result desired.

Trouble due to misapplication in any of these respects is entirely eliminated by the instrument referred to, which indicates the critical point, not as a degree of temperature, but as a non-magnetic state. The instrument consists of a contact box containing magnet and coils, mounted on one end of a rod provided with handles and heat shield. The other end of the rod carries a magnetic flux meter; the needle of which indicates the gradual approach of the steel to the non-magnetic, or critical point. Immediately contact is made with the steel in the furnace through the medium of the magnetic coils, the needle indicates the degree of magnetism in the metal, all knowledge of the actual temperature being irrelevant, so far as the indication of the critical temperature is concerned.

The makers of this instrument are the Gibb Instrument Co., Pittsburgh, Pa.



MAGNETIC INDICATOR FOR CRITICAL TEMPERATURES OF STEEL DURING HEAT TREATMENT.

ONTARIO BOILER RULES REVISION

A PROPOSAL is under consideration to revise the Rules and Regulations covering the construction and inspection of steam boilers in the Province of Ontario. A meeting was called by Dr. Riddell, superintendent of the Trades and Labour Branch of the Department of Public Works at the Parliament Buildings, Toronto on Dec. 28, for the purpose of ascertaining the views of those interested. It is proposed to prepare a Bill for presentation before the Provincial House, which will be a revision of the Act already in force. The delegation consisted of representatives of steel and cast iron boiler manufacturers, boiler inspectors, stationary engineers.

Dr. Riddell in calling the meeting to order asked for a frank discussion of the proposed rules and said he would be glad to receive any suggestions that might be helpful in the preparation of a Bill that would meet with the approval of all the interests concerned. The proposed rules which were read by D. M. Medcalf, chief boiler inspector were discussed in detail and suggestions taken down in the minutes.

At the conclusion of the meeting it was decided to send copies of the minutes to all boiler manufacturers, inspection companies, etc., who will in turn submit their views to Dr. Riddell. It was further decided to appoint a committee composed of two representatives from each of the following interests:—Steel boiler manufacturers, cast iron boiler manufacturers, boiler inspection companies, stationary engineers, boiler users, and manufacturers of fittings. The committee will confer with Dr. Riddell and will be authorized to make any suggestions which will tend to improve the present Act.

AN alloy has been produced which is claimed to be an entirely satisfactory substitute for platinum, either as crucibles or as ignition tubes, thermo couples, etc. The new metal is called rhotanium, and is reported to be an alloy of metals of the platinum group. The price of the new alloy is the same as that of platinum, but its specific gravity is about half that of platinum.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

FUSE-GRADUATING MACHINE

THE fuse-graduating machine shown in the illustration has been developed for the purpose of graduating fuse rings and bodies, a work which calls for extreme accuracy. The fuse body is held in an air-operated draw-in collet chuck, carried in a chuck shaft or spindle supported in two bearings. The graduating die is carried on the inner end of the belt driven shaft which is located at a suitable angle, and is geared to the work spindle through a train of bevel gears arranged to give a relative reverse motion between the two members.

Ordinary punch-press trip gear is fitted to the belt pulley, which allows the parts to make one revolution only for each pressure on the foot lever. The graduating dies generally have a blank space which is arranged to be next the work when stopped; as the work can thus be placed in position or removed without setting back the dies, this allows the dies to be set to their full depth. Marking is done ordinarily in one revolution, although if the material be unusually hard, two or three revolutions may be required.

The gears used are approximately four times the diameter of the work, and all backlash is removed by suitable adjustments to insure complete accuracy.

Pressure of the die on the work is obtained by suitable weights operating through a bell crank, additional weights being added as the die becomes dull. In certain types of fuses the pressure is great enough to disengage the work from the chuck and the necessary support is obtained through toggle arrangement shown which maintains a supporting arbor against the work during the marking. The illustration shows the general appearance of the machine which is built by the American Ammunition Co., Bordentown, N.J.

FORMED CUTTER RELIEVING MACHINE

THE accompanying illustration shows a backing-off machine for relieving formed cutters which is built by the Becker Milling Machine Co., Boston, Mass. It is designed to give straight or peripheral, side and end relief for all work within its capacity.

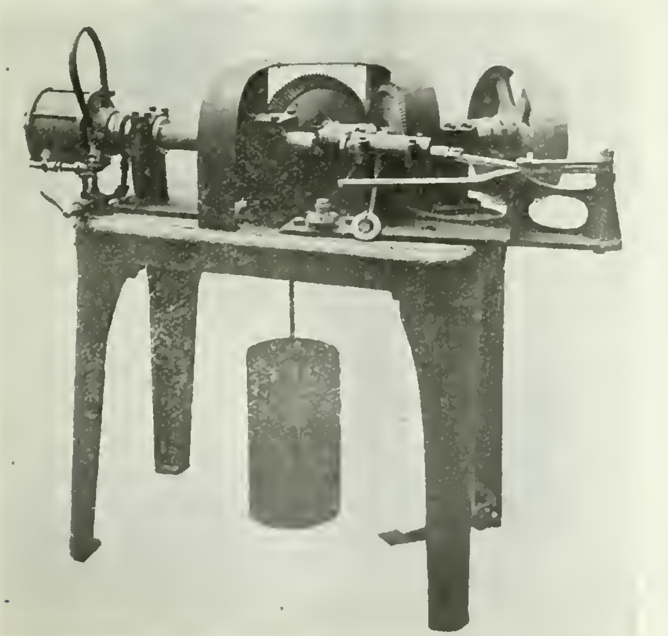
It is of the arm type of construction, special ways being provided for maintaining alignment of the tailstock which is secured in place on the arm by four clamping bolts, the maximum adjustment of the tailstock being 24 in. The spindle is machined from crucible steel and has a maximum diameter of $3\frac{3}{4}$ in. It runs in solid phosphor-bronze bearings having compensation for wear, and is driven through a spur gear mounted directly on the end. A No. 13 B. & S. taper hole is provided in the spindle, accommodating a $\frac{3}{4}$ in. draw bolt, clutch drive from the spindle nose insuring positive rotation of the tool to be relieved.

The cam shaft operates a single throw cam at the back of the machine, giving relief from zero to $\frac{1}{4}$ in., the wear on cam rolls being taken up by tapered gib to insure positive throw. The cutter to be formed or relieved, can be placed in proper relation to forming tool without loosening bolts or nuts by operating a worm meshing with a wheel positive with the cam shaft, a micrometer stop attached to peripheral relief slide enabling the tool to be accurately reset at each change of work. The peripheral and side relief are operated by the same cam, while the end relief is operated by a sparate cam at end of bed. Either collar bearings or center bearings may be used in the tailstock according to the requirements of the work.

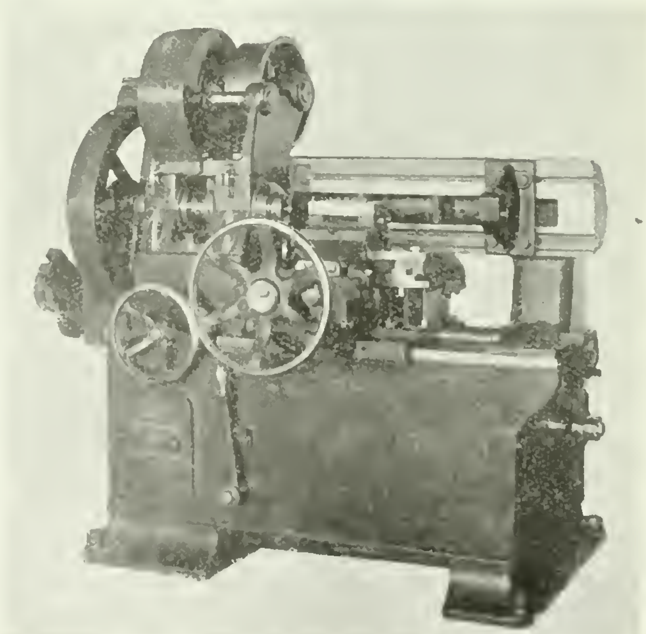
Tools from $\frac{1}{4}$ in. to 1 in. in thickness can be held in the block which is set on a 30 deg. slide plate and operated by small handwheel at side to raise on lower tool to required adjustment. The tool is fed to the work by a handwheel provided with accurate differential control for fine feed, which is thrown out of gear when making quick adjustments. Longitudinal adjustment is obtained by a carriage screw operated by handwheel through bevel gears, the maximum adjustment being 12 in.

The machine will relieve cutters up to 13 in. dia., with flutes from 3 in. to 12 in. inclusive, the flutes being even numbers from 12 to 40 inclusive. Holes and worms can also be cut to good advantage.

When motor driven, a 3 horse-power variable speed motor is mounted at back of machine. The total weight is approximately 6,500 lbs. and floor space, 68 x 48 x 64 ins.



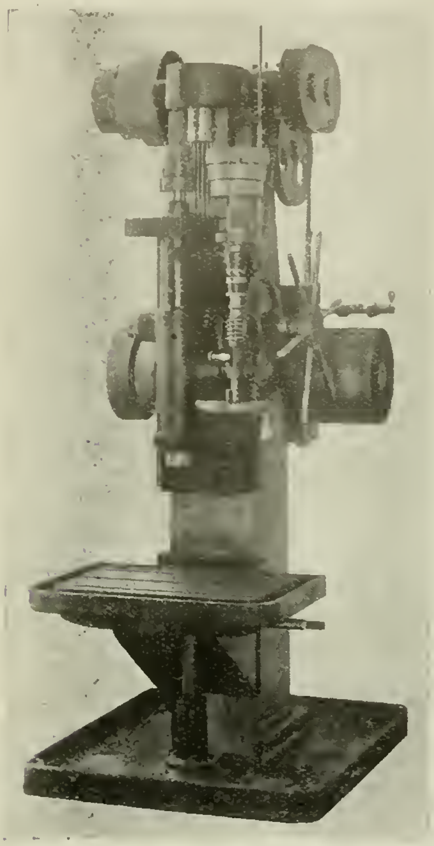
FUSE RING GRADUATING MACHINE.



FORMED-CUTTER RELIEVING MACHINE.

TRAVERSING HEAD DRILL PRESS.

AN interesting departure from regular drill press practice is shown in the accompanying photograph of a heavy duty single spindle traversing head drill press recently added to their line by the Moline Tool Co., Moline, Ill. In place of the spindle being mounted in a quill fed by rack and pinion, it is carried in long adjustable bronze bushings mounted in the head, the entire head with feed gear works being traversed up and down by a double rack and pinion.



TRAVERSING HEAD VERTICAL DRILL PRESS WITH BELT FEED.

This method of construction enables the spindle diameter to be kept large where the spindle drive gear is mounted, dispensing with the reduced spindle diameter of conventional design, which is further weakened by splining for driving keys. The spindle gear is driven by a wide faced vertical pinion, the vertical movement of the head causing the spindle gear to travel along the face of the pinion, which is supported its entire length, runs in bronze bushings, and is driven by steel and bronze spiral gearing from a three-step cone pulley. Between the pulley shaft and the spiral pinion are two sets of change gears giving speeds ranging from 20 revs. per min. to 200 revs. per min. Gear box feed can be supplied in place of belt feed shown in cut.

The principal dimensions are as follows: Centre of spindle to face of column, 10 in.; max. distance, table to spindle, 34 in., in floor type machine, 46 in.; table has three tee-slots, oil catching rim, and working face, 15 in. x 24 in.; vertical travel of table, 15 in., of head, 18 in.; spindle dia., lower bearing 2 15-16 in.; pump and piping regularly included.

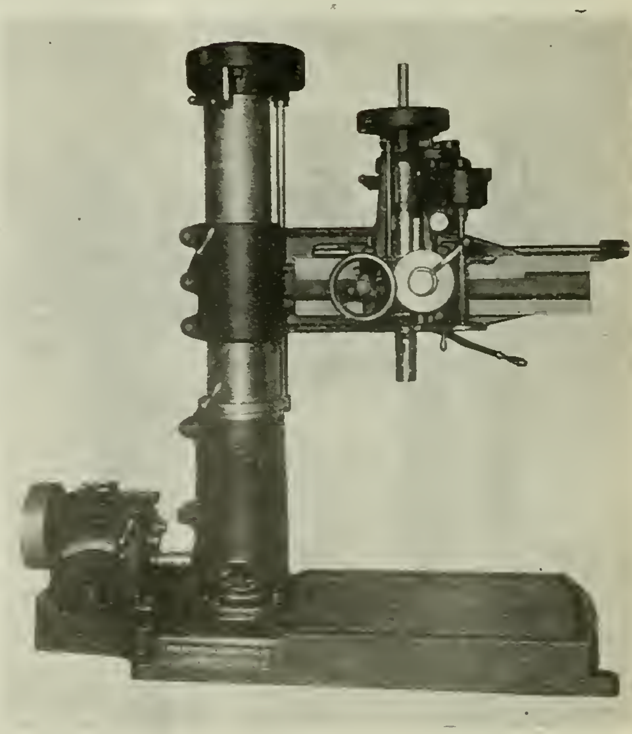
NEW LINE OF RADIAL DRILLS

A NEWLY designed line of radial drilling machines consisting of 2½, 3 and 3½ ft. machines has been placed on the market by the Morris Machine Tool Co., Cincinnati, O. The machines embody all the necessary features of modern manufacturing tools, and are capable of driving high speed drills at their maximum speeds, as well as doing tapping facing, counterboring, etc., with ease on the part of the operator.

A large diameter column, mounted on roller bearings, is carried on a heavily designed stump, bolted and doubled to the base, projecting into the stump sufficiently far to insure alignment under heavy strain. The deep base is well ribbed and provided with large tee slots, and oil channel round the base draining into a large reservoir.

The arm bearing on the column is wide, has adjustment for wear, and is clamped in position by a single lever. The arm itself is of pipe section with a heavy rib above and below. The arm elevating screw is operated through tumbler gears so arranged that their tendency to disengage compels the operator to keep his hand on the elevating lever while in operation. Any attempt to elevate the arm while clamped, or in extreme positions renders it impossible to keep gears in mesh. The head is of substantial construction and slides on hardened ways on the arm by rack and pinion. The spindle is a hammered forging of high carbon steel, having ball thrust bearing, and graduated sleeve fitted with direct reading depth gauge and automatic feed trip Ten spindle speeds are secured on the cone drive machine and twelve on the speed box drive.

Steel gears are used throughout and all bearings are of phosphor bronbe fitted with oil chamber and felt wiper.



NEW MODEL RADIAL DRILL MADE IN 2½, 3 AND 3½ FT. SIZES.

C. P. R. TUNNEL THROUGH SELKIRKS

TWO important results will follow the completion of the C. P. R. Connaught tunnel in the Selkirks—first, the elimination of all danger from snowslides; second, the discontinuance of the upkeep of five miles of snowsheds. The ventilating system, which is now being installed, and which is in a very forward state, is most thorough in its layout and equipment The desire is to keep the smoke and gases away from the engineers and firemen on the locomotives on their trip through the tunnel. The train will travel uphill from the eastern to the western end at the rate of about 20 miles an hour; but the smoke and foul air will be pushed down the hill at the rate of about 12 miles an hour—thus driving the smoke away from the engines.

The ventilating fans are driven by two oil engines, which are in duplicate against emergencies, and no effort has been spared to make the plant the most complete possible, the idea being to have the tunnel as safe from every point of view as any other part of the line. Ten or twelve minutes are required to negotiate the five miles of tunnel.

Another Bloke.—"Who was this 'ere Nero, Bill?" asked a coster of his friend as they gazed in the picture shop. "Wasn't he a chap that was always cold?"

"No, that was Zero," was the answer. "Another bloke altogether."

British colonies total 13,002,321 square miles in area, with a population of 389,065,035.

Vol. XVII. JANUARY 4, 1917 No. 1

OUR 1917 MUNITIONS OPPORTUNITIES

GREAT as have been our opportunities during the past two years to secure contracts for the supply of munitions to Great Britain and her Allies, and in spite of the fact that we have given evidence of a generous response as regards output, still greater opportunities are awaiting us, and, correspondingly, the onus of a very much increased production comparatively. Munition orders amounting to several hundred millions of dollars are being and will be placed with Canadian metal-working plants, in which connection it is learned from a highly authoritative source that during the past week or ten days an order for shells, variously estimated as worth from $175,000,000 to $200,000,000, has been placed with a prominent Montreal plant.

From time to time recently, reference has been made in our columns to the fact that, while orders for raw materials may continue to be placed in the United States, those for finished shells were on the eve of being discontinued. Notwithstanding, it was hardly believed that the transfer to Canadian metal-working plants could be carried out in toto, as is now planned, a suspicion being existent that the capacity, if not also the efficiency of the latter were unequal to the task. Further, it had been supposed that the hundreds of munition factories which have sprung up in Great Britain, France and Italy would take over the work. News that Canada has developed facilities to handle a shell business which may amount to fully $400,000,000 during this year, has been, to say the least, some surprise, more especially when it is recalled that during 1915 and 1916, sections of numerous Canadian shell orders were placed in the States to be filled.

Several important influences have been operative to cause Allied munition buyers to switch shell-making to Canada. In the first place, of course, there is a desire to utilize the facilities of a country having a direct part in the war, whose plants and workmen will profit from the business. Another consideration is the economy to be effected in having the finished goods turned out close to the base of supplies of raw material. Whether, however, the Allied war material is made in Canada or in Europe, a great part of the steel rounds and metals used will have to come from the United States. As completed shells can be shipped across the Atlantic cheaper than steel, copper and zinc, in the rough, it is naturally in keeping with the economic plans of the fighting nations to have munitions made up on this side of the water.

As a result of the foregoing developments, we may expect Canadian bankers to continue to furnish the necessary accommodation to our Imperial Munitions Board, in quantity commensurate with the resources at their disposal; and, on occasion, when supplementary measures become necessary, to influence by co-operative effort the successful flotation of either domestic loans or their consummation with United States bankers, thus relieving the Imperial Treasury, and adding to the strength of its credit in world markets.

As we go to press, advices reach us to the effect, that an additional $50,000,000 credit from Canadian Banks to the Imperial Government for the purchase of munitions and supplies in Canada has been arranged, same having been under negotiation for some two weeks past. This new credit makes a total of $250,000,000 provided by our banks and Government for the purposes mentioned, and all within the space of one year.

CANADA'S NATIONAL SERVICE WEEK

THESE, the opening days of the New Year, 1917, constitute what is known as Canada's National Service Week, and, as will be gathered from what follows, the response of our citizens to its aims and purposes is expected to be both prompt and hearty. Our men are interested because it is obligatory upon each of them, between the ages of 16 and 65 years, to fill out one of the cards which the Government is sending to them through the Post Office authorities. Our women are interested because their co-operation is being invited, in seeing that their men-folk attend to this important duty. Our children are interested because their school teachers have explained to them the meaning of National Service and the way in which father and the big brothers at home have to reply to the various questions.

To write in the answers and return the card promptly is a good NewYear's resolution for every man throughout the Dominion; it has the advantage of being easy of fulfilment. It only means a few minutes' careful thought. The postman in the cities gets the hard work, for he has not only to deliver the cards, but he is responsible also for their proper return. Prompt mailing of the answers will make the postman's work very much easier.

National Service means that we are to get into that frame of mind which will cause us to think of the needs of the country, to realize that the interests of the State have a greater claim on us than our self-interest. This applies to everyone, from the highest in the land to the lowest. The Prince of Wales' motto, "I serve" may well be the motto of every citizen of the British Empire at this time. There are many ways of serving the nation besides going to the front. The man on the farm and the mechanic in a workshop may be serving the nation as usefully as the man in the trenches. In a word, every man should be doing the work which represents his most efficient service to his country.

The war is teaching us, or should be teaching us, great lessons. Terrible as are its effects, those who have faith in Canadian manhood, hope and believe that the nation will emerge from this experience, bigger, stronger and better. If the meaning of National Service is thoroughly grasped and properly understood, if the Government's call for information is responded to in the right spirit, 1917 will be the banner year in Canada's history.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., Dec. 30.—The action of the Allies in counteracting Germany's peace manoeuvre, coupled with the recent decision of the British Government to place an ever-increasing proportion of munitions contracts in Canada are the two most significant events influencing business at the close of the year. The former of these events imparts a more definite and decisive atmosphere to all activities connected with the conduct of hostilities, the ultimate result of such a decision tending to maintain prices firmly at present high levels but without the prospect of any further spectacular advances. The latter event insures a high degree of productive activity in nearly all branches of Canadian industry. In the iron and steel industries considerable inconvenience has been caused by car shortage and weather conditions interfering with the supply of raw materials, while business in certain metals has been directly affected by the recent censorship of shipping news.

Pig Iron

Prices continue strong but a tendency to reform further buying in some quarters has eased the situation slightly and prevented further advances in price which were becoming altogether too frequent for a satisfactory state of affairs.

Steel

Billets and sheet bars are still in heavy demand and Pittsburgh quotations have been advanced from $3 to $5 per ton, the nominal price being $65 per ton. The extreme demand for wire rods has resulted in a sharp advance, the quotation of $80 per ton, being an advance of $10 during the week. Forging billets show a similar advance the nominal price being $85 per ton. Black sheets have moved upwards to $5.50 Pittsburgh an advance of $10 per ton. Galvanized sheets at a corresponding advance are quoted at $7.00 Pittsburgh

Metals

The general situation is rather unsettled owing to the current political developments, both here and abroad. The action of Great Britain in more closely controlling the distribution of material for manufacturing purposes, together with the restriction of shipping information has resulted in placing the trade in a somewhat nervous and uncertain condition.

Copper.—The market is quiet and unsettled. Quotations are lower on the British market, following the action of the authorities in curtailing the use of this metal. A census of copper is being made to determine the amount of metal, both stock and on contract, that is available, with a view of more economical use of the supply and to regulate the future consumption. New York quotations are lower, the price of lake, after a decline of ½c, being 31½c per lb. Electrolytic at the same price shows a decline of 1½c. Dealers here report a quiet market and a weakening tendency, the quotations this week having declined 1c per lb. Prices this week are 36c for lake and electrolytic, and 35c for castings.

Tin.—The market has been disturbed by the action of the British Government in restricting the publication of information regarding shipping movements. This will mean that the trade will experience much uncertainty as to the amount of tin in transport and will consequently result in an unsteady market. Both London and New York have declined on price quotations, the latter quoting 40¾c, a drop of one cent on the week. The situation here is comparatively firm but developing a weaker tendency. Tin is nominally 46c per lb.

Spelter.—The market though easier is showing a firmer tone, having become more active during the past week. However the situation in this metal is largely affected by current conditions and the early future is an unknown factor. All markets are lower, New York having declined ½c, the nominal quotation being now 9¾c per lb. The local situation is quiet and prices have declined ½c; the quotation this week being 13½ cents per lb.

Lead.—The market remains firm but quiet, although not sufficient to affect the current quotations. Should the uncertainty that prevails continue, the situation will probably develop a weaker tendency. The firmness of the present market is partly due to a temporary scarcity. New York continues to quote 7½c on "Trust" metal with the outside interests ⅛c higher. Dealers here are still quoting 10c but would not be surprised to see an early decline.

Antimony. — In common with other metals, antimony is experiencing a dull period owing to existing conditions. Quotations are however holding firm, prices here being steady at 15c per lb.

Aluminum.—The market is unchanged but with an easier tendency. Dealers here are quoting 69c being a decline of 1c per lb.

Machine Tools and Supplies

The holiday season has been reflected in a decrease in machine tool activity, and added to this the situation is partly affected by the indefinite knowledge of early future conditions. However the nervous feeling is somewhat offset by the ever increasing volume of domestic inquiry that tends to develop into greater proportion with the assurance of ultimate peace possibilities.

Scrap

Following the quiet of the past week or so, the quotations on old materials have become easier, more especially on the metals; the strength of iron and steel scrap being well maintained although a weakness has developed in some lines. Coppers have fallen off 1½c per lb., the quotation ranging from 21c for light to 25c for heavy and crucible. Machine compositions and turnings are 1½c lower, prices being 20½c and 16½c respectively. Brass clippings are now 17c, and scrap zinc 8c; both having declined ¼c per lb.

Toronto, Ont., Jan. 2.—The refusal of the Allies to enter into peace negotiations at the present time will help to clear the air of business uncertainty recently in evidence.

The year just closed has been one of remarkable prosperity for Canada, and this new year, so far as can be seen at the present time, promises to eclipse its immediate predecessor. Many industries have developed to such an extent that variety of output as well as volume has increased to a surprising extent. There has been a remarkable expansion in export trade, while Customs revenues have also made a big increase. For December the Customs revenue amounted to $11,884,000, as compared with $9,432,000 for the corresponding month of last year. In the nine months of the fiscal year the Customs revenue has reached a total of $106,613,000, an increase of $34,891,000.

Steel

The market has been quiet during the holiday season, as is usually the case, consequently there are no price changes to note. The New Year opens with the iron and steel trade in a sound position, with a year of big business undertaken and good prospects for another twelve months, or at the least a good part of it, of at least equal activity. Much depends, of course, upon the duration of the war, but the mills are already assured of practically twelve months' business, it being unlikely that any contracts now placed will be cancelled. If peace be declared during the year, it is more than likely that the tonnage will be delivered in some form other than munitions. The productive capacity of the mills has been greatly increased and requires a corresponding increase in volume of business to keep them operating at capacity. To what extent this output will be required after the war is a matter of speculation, but it is there to be taken advantage of, if needed. While there will probably be a subsidence of peace talk for some months, prices may be subject to more or less disturbance. The situation in the steel trade at present is similar to that of last June, when it was generally thought that prices had about reached the top. Whether the upward movement has stopped or not is a matter of conjecture, but there is little doubt that the peace talk has already affected the market to some extent, and that it will help to check any upward tendency in prices. Some steel products, such as black sheets and plates, are expected to reach higher levels regardless of the general trend of the market, as the situation in each is rather exceptional.

As regards black sheets, the mills are experiencing a shortage of sheet bars, while the scarcity of labor is helping to curtail the sheets output. Most large sheet mills have no material to offer for first quarter delivery, while some have made fairly large sales for second quarter. The leading interest in the U. S. has advanced prices which will affect the local situation in due course. The demand for plates continues heavy, and most mills are sold up for the whole of 1917. The market for wire rods continues very firm at advancing prices. It is understood that Canadian interests have paid $80 a ton at mill for wire rods in the U. S.

Pig Iron

The pig iron market is quieter, and no further price changes have been made. Prices on domestic brands of pig iron are still withdrawn, and no intimation has been made as to when new prices are likely to be issued. The pig iron market in the States is quieter, buying being lighter owing to limited amounts of iron available and congested freight conditions. There have been no price changes in the U. S. on pig irons.

Machine Tools

There is a seasonable quietness in the machine tool market, the transactions this week having been comparatively light. Renewed activity is, however, looked for this month, principally in equipment for munition plants. Prices of machine tools continue to advance, affecting particularly lathes, drilling machines and power presses. A firm in the U. S. has advanced prices 12½ per cent. on 12-in. to 30-in. lathes, making quotations now 65 per cent. higher than two years ago. Drilling machines, including radial and upright drills, have advanced 10 per cent. recently, making prices about 50 per cent. higher than two years ago. On power presses the advances range from 5 to 10 per cent., making quotations about 50 per cent. higher than two years ago.

Supplies

On account of the holidays, business has been quiet during the week. It is understood that new and higher prices on lubricating oils will be announced very shortly, due, it is stated, to the higher cost of crude oil, which has recently advanced. Gasoline is unchanged in the meantime, but very firm. Pennsylvania crude oil advanced 10c a few days ago, and is now quoted at $2.85 a barrel, Pittsburg, the highest price ever quoted for this grade. Other grades were each advanced 5c. The advances were brought about by the continued demand of refiners, who state that there is an abundance of oil above ground, but producers are holding it for still higher prices. Jenkins globe, angle, and check valves have advanced approximately 7½ per cent., the new discount being 15 per cent. on standard grade. Gate valves are now selling at 20 per cent. off list. Iron body gate and globe valves are quoted at 40 per cent. off.

Metals

The metal market has been seasonably quiet this week on account of the holidays and stock-taking. The situation with regard to most metals is unchanged, and prices are the same as were recorded last week. The temporary passing of peace talk will tend to make the markets firmer, but any pronounced upward movement in any metal is very unlikely. The possibility of peace proposals being renewed later on in the year will tend to check any tendency to inflated prices.

Copper.—The market is steadier, but quiet. Producers, in view of their sold-up condition, have not changed their quotations for any part of the first half. There is practically no spot copper to be had except resale metal, which has been quoted under the market. Local prices are unchanged and nominal at 36c per pound.

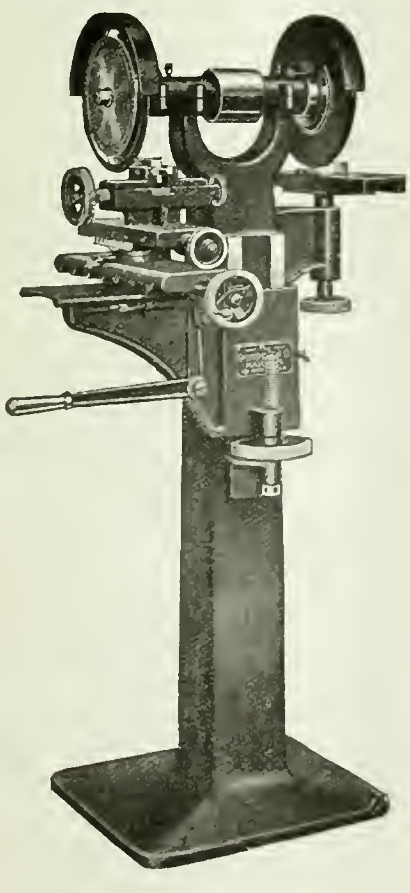
Tin.—The market is dull and unsettled, although there has been no change in prices. The action of the British Government in prohibiting the publication of steamship arrivals and departures has affected the tin market, as the movements of tin cargoes cannot be followed by the trade. Local price, 45c per pound.

Spelter.—There has been no change in the spelter situation at the mines; the market is steadier and quiet. Local price, 13c per pound.

Lead.—There is some scarcity of lead, but quotations are unchanged, with the market quiet. Local price, 9½c per pound.

Antimony.—The market is very dull, with prices nominal and unchanged at 18c per pound.

Aluminum.—The situation is unchanged, but the market has an easier tendency. Local price, 68c per pound.



INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Toronto, Ont.—The Gutta Percha & Rubber Co. will build an extension to their power house.

Toronto, Ont.—The Wm. Davies Co. will build a smoke house addition to their plant at 529 Front Street, to cost $3,000.

Toronto, Ont.—A building permit has been granted to the Consolidated Steel Co. for the construction of a machine shop at 1154 Dundas Street, to cost $2,500.

GENERAL INDUSTRIAL

Montreal, Que.—The Canadian Starch Co. will build an addition to their factory at Cardinal, Ont.

Tillsonburg, Ont.—The Huntley Mfg. Co., Silver Creek, N.Y., builder of cereal-milling and canning machinery, has purchased a site here and will build a factory.

Toronto, Ont.—Fire on December 28 destroyed the King Street car barns of the Toronto Street Railway Co., causing damage estimated at over $500,000, which is covered by insurance. About 70 cars were destroyed and a portable air compressor outfit.

MUNICIPAL

Port Arthur, Ont.—A by-law to renew a power contract with the Hydro-Electric Commission was carried by 780 to 20.

Clinton, Ont.—The waterworks extension by-law was carried here on Monday by a majority of 4 to 1, and the Hydro by-law by 2 to 1.

Oshawa, Ont.—At the elections on Monday, the by-law to vote a bonus to the McCulloch Foundry was carried by a majority of 62.

Palmerston, Ont.—The Hydro-Electric by-law' to acquire and develop more power was carried six to one, only 11 voting against it.

Amherst, N.S.—The Town Council contemplate the purchase of a motor-driven centrifugal pump in connection with the waterworks system.

Gananoque, Ont.—The voting on the by-law granting the Steel Co. of Canada the present fixed assessment for ten years resulted as follows:—For, 247; against, 192.

Seaforth, Ont.—Two by-laws were voted upon here on Monday. The Jackson Clothing Co. by-law was defeated, standing 49 for, 132 against. The firm asked $250 a year for ten years to operate a branch factory here.

Brantford, Ont. — The City Council contemplate installing a mechanical filltration plant.

Ottawa, Ont.—At the elections on Monday, the ratepayers voted $50,000 for a civic garbage collection plant and $75,000 for public swimming baths.

Lindsay, Ont.—The by-law to allow a fixed assessment on the new plant of Flavelles, Ltd., cold storage and egg house was passed by a very large majority.

Toronto, Ont. — The Township of Etobicoke propose to construct a waterworks system at an approximate cost of $75,000. E. A. James, of Toronto, is the consulting engineer.

Woodstock, Ont.—The result of the vote on the Hydro by-law resulted in an overwhelming majority for the by-law of over 900, very little opposition being shown. The vote stood—1,025 for, 7 against.

Walkerville, Ont.—The by-law empowering the Town Council to consider the deal with transportation problems in the municipality was carried by a large majority, as was also the Hydro-Electric by-law.

Toronto, Ont.—At the elections on January 1, the vote in favor of tue municipal ownership of the Hydro development generation plant was overwhelmingly large; out of a total vote of nearly 22,000 only 1,566 people voted against the proposition.

Toronto, Ont.—The Board of Control recommends that the Works Department be authorized to purchase the following suplies during 1917 in the open market: Iron and steel, pig lead, paving pitch, pipe and boiler tubes, rubber valves, etc.

Owen Sound, Ont.—The ratepayers voted on Monday on by-laws to loan the Keenan Woodenware Mfg. Co. $20,000 to extend their plant and to authorize the purchase of a motor truck for the Fire Department. The Keenan by-law carried, 923 to 152, while the motor truck proposition was defeated by 433 to 566.

Bridgeburg, Ont.—All the by-laws for the Welland, Port Colborne & Bridgeburg Radial Railway carried on Jan. 1 by large majorities, probably five to one. Fort Erie was considered a doubtful point, but there were only eight votes against it there. Humberstone Township carried it by four to one.

Chatham, Ont.—The Hydro extension by-law and the Patriotic Fund by-law, the latter providing for raising $600,000 for the Patriotic Fund by taxation this year, were both carried with large majorities. The fire truck by-law was defeated at the municipal election on January 1.

Brantford, Ont.—At the elections on Monday, two by-laws, one as to a proposition to develop the question of a municipally owned gas plant to be placed before the people, and one giving the city authority to enter into the Chippewa power development scheme, were carried by big majorities.

London, Ont.—On January 1 the industrial bond guarantee by-law, covering a scheme for the inducement of industries to locate here after the war, was given a majority of 999, but will not become operative because a two-thirds majority, which was necessary, was not secured. The vote stood—2,886 for and 1,887 against.

Hamilton, Ont.—At the elections on Monday, seven by-laws were submitted to the people, with the following results: The plebiscite on the question of Hydro-Electric power development was carried; that to raise $50,000 for improvements at the Mountain Sanitarium was carried by a large majority; that to endorse the expenditure of $6,000,000 on the Hydro-Radial Railway prospect was lost by a small majority; to expend $25,000 on filling in the Sherman Avenue inlet, defeated; to expend $61,000 on the construction of a storm sewer, defeated by a large majority; to expend $362,500 on steam pump at the waterworks station, negatived.

TRADE GOSSIP

Marine Insurance Raised.—The *Daily News*, London, England, says that owing to the increased submarine menace, the Government War Risk Insurance Office has raised the insurance rate per voyage for British vessels to forty shillings per cent.

Prohibition Raised. — C. Hamilton Wickes, his Majesty's Trade Commissioner in Canada and Newfoundland, has received the following cable from the British Government's Board of Trade, London:—"Strontium compounds and mixtures prohibited United Kingdom. 19th December, various fibres and jute piece goods, threads, yarns, twist webbing no longer prohibited."

Toronto, Ont.—The Royal Securities Corporation has become associated with the financing of the Mattagami Pulp & Paper Co., to develop the resources of this concern, which owns 125 square miles of freehold timber limits on the Mattagami River, Northern Ontario, estimated to contain over 4,000,000 cords of spruce pulpwood. For over a year the company has had under construction a sulphite pulp plant, capable of producing 45,000 tons. S. R. Armstrong has been appointed manager.

The S. K. F. Ball Bearing Co., Hartford, Conn., are reorganizing their Canadian branch the S. K. F. Ball Bearing Co., and have opened offices at 47 King Street West, Toronto.

The Michipicoten Power & Paper Co., which has recently ben incorporated with a capital of $6,500,000 propose to build a 150 ton news print mill at Michipicoten Harbor on Lake Superior. L. M. Wood of Toronto is president of the company.

Canada's Revenue Increase. — The close of the calendar year 1916, found the revenue of Canada well in advance of the receipts for 1915. The Customs revenue for the December just closed amounted to $11,884,000, as compared with $9,432,000 for the corresponding month in 1915, an increase of $2,451,000. In the nine months of the fiscal year the Customs revenue has reached a total of $106,613,000 an increase of $34,891,000.

Marine Insurance Higher.—It is reported from New York that marine insurance rates on Dec. 30, showed another increase. Underwriters quoted 6 to 8 per cent. for insurance of cargoes bound to ports of the United Kingdom and 10 per cent. to Mediterranean ports. A few days ago these rates stood at 5 to 8 per cent. The advance was attributed to reports that the Lamport & Holt lines Voltaire, long overdue, had been captured.

Absence of Labor Troubles—The year 1916 ended with practical immunity from labor troubles in Canada. Only one Board of Conciliation has been sitting of late, and its report was recently submitted. It deals with the application of employees of the Ottawa city waterworks for a 15 per cent. increase. The Board unanimously recommends individual increases, which amount to ten per cent. in every case, and in some instances to more than 15 per cent. Forty-five employees of long standing are affected.

Russian Language at McGill—McGill University is offering during the last half of the present session a course in the Russian language. This is the first time that instruction in Russian has been given by any Canadian University. It is an interesting departure, as indicating that the present war alliance is destined to develop into a permanent relationship of commercial intercourse. The present course is designed for beginners and is meant to meet the needs of business men as well as of students of language and literature. Full information about the class can be had on application, in writing or by telephone, to the Registrar of the University.

New Brunswick Lumber.—New Brunswick lumber production for the calendar year 1915 amounted to 635,518,000 feet, board measure, compared with 414,808,000 in 1914. These figures were obtained from 240 active mills. In the production of spruce, balsam, fir, white pine, and many of the minor classes of lumber in New Brunswick, the returns show a considerable increase in 1915 over 1914. In the quantity of hemlock sawn there was a noticeable decrease, while in 1915 it composed only 2.4 per cent. The total value of 1915 production is given as $9,902,202.

New Copper District.—During the past twelve months development work has been carried out on a new copper discovery at Newport, County of Gaspe, P.Q. Some very rich ore has been taken out on wide veins assaying as high as 57 per cent. copper content in massive ore from 14 veins already uncovered. Over a large area assays run in payable ore. American interests are contemplating larger development on the recommendation of expert geologists, who have made exhaustive examination of the properties.

Toronto, Ont.—Thorough-going endorsation of the Hydro-Electric extension was given on Monday by the municipalities voting on the question of municipal development of the Chippewa Creek-Niagara Falls power. The question was submitted in practically every municipality having a contract with the Hydro-Electric Commission, and with one exception—Goderich—the cities and towns of the Niagara system voted overwhelmingly for the principle of municipal development of power. In some places opposition was practically nonexistent, less than half a dozen votes being polled against the proposal in several places.

Trawler Inquiries — The Submarine Boat Corporation of New York, which was incorporated in August, 1915, to take over the business and stock of the Electric Boat Co., has had agents in Canada endeavoring to place orders for the construction of the 200 trawlers for which it has contracts with the Admiralty. Several Montreal firms have been approached. It is thought unlikely that Canadian firms will be able to take any considerable portion of the business, since they had already refused the whole of the original order before it was offered in the States. The contract calls for 200 trawlers, each 100 feet long, equipped with 500 h.p. Diesel engines, and costing $150,000.

Toronto Exhibition — The financial ment of the Canadian National Exhibition for 1916 was presented to City Treasurer Bradshaw on Saturday last by president Noel Marshall, manager Dr. Orr and treasurer Brentnall. It revealed that the profits of last year's fair were approximately $77,000, and that the attendance reached 910,000. These figures have only been exceeded once before in the record year of 1913. The distribution of the surplus will be as follows: $34,613.19 to the city, $8,044.99 towards the cost of the new eastern entrance, $25,000 for the construction of new lavatories as approved by the City Council and $10,000 reserved for working expenses.

U.S. and the "Deutschland"—The absolute secrecy with which the merchant submarine Deutschland, and, later, the fighting submarine U-53, made their way into the Chesapeake and Narragansett Bays, should serve as a note of warning to the United States, says the *Scientific American*. Whether or not the German Government sent this fighting submarine across for the express purpose of showing the United States that she was capable, if she wished, of running amuck among her shipping, the instant it ventured beyond the three-mile limit, is a matter for conjecture. "This much is certain," says our contemporary, "that after these visits it will be our own fault, and not Germany's, if we fail to realize that what she did to merchant shipping off our coasts, she could just as easily do to the naval and merchant shipping within our own dockyards and harbors."

U.S. Tin-Plate Manufacture—Official returns show the extent to which American manufacturers of tin-plates have secured a footing in foreign markets since the outbreak of war. In the fiscal year ended June 30, 1916, the exports from the United States amounted to 230,472 tons, as compared with 80,009 tons in the year 1914-5, and 47,276 tons in 1913-14. Some indication of the breadth of the area of distribution of the export trade is obtainable from the following figures showing the destinations and volume of the shipments in the fiscal year ended June 30, 1916, the corresponding figures from the year 1913-14 being in parenthesis: Great Britain, 29,783 tons (nil); Canada, 52,394 tons (3,310 tons); Argentine, 18,717 tons (1,282 tons); Brazil, 11,848 tons (805 tons); China, 15,807 tons (4,012 tons); British-Indian, 20,334 tons (9 tons); Japan, 24,647 tons (191 tons); other countries, 33,250 tons (3,685 tons).

Accidents in Metallurgical Plants — Fatal accidents reported at metallurgical plants in the United States in 1915 were 68, of which 30 were in ore-dressing plants and 38 in smelters. In 1914 these were 23 and 33 respectively. These data are from the second report of the Bureau of Mines on accidents at metallurgical works, and cover returns from 110 smelting plants in 1915 as compared with 94 in 1914, and include copper, lead, zinc and quicksilver smelters, as well as refineries, but do not include iron-blast furnaces. They represent also concentrating plants for copper, lead and zinc ores, stamp mills, cyanide plants and iron-ore washers. Non-fatal injuries at ore-dressing plants in 1915 were 2,095 and at smelters 5,718; these were 1,434 and 5,673 respectively in 1914. There were 63 permanent partial disabilities at ore-dressing plants and 87 at smelters. Total men employed were 49,891 in 1915, as compared with 41,461 in 1914.

WOODWORKING

North Vancouver, B.C.—The Canadian Robert Dollar Co. will build a saw mill and wharf here.

Wiarton, Ont.—Fire on December 24 completely destroyed the local branch factory of the Canada Furniture Manufacturers, Ltd., the main factories of which are at Woodstock. The loss is estimated at $75,000, which is partly covered by insurance.

PERSONAL

W. G. Ross, chairman of the Montreal Harbor Commissioners, has been appointed director of naval recruiting in the Province of Quebec.

Frederick J. Brule has resigned from the staff of the Anaconda Copper Co., to accept the position of chief engineer of the British American Nickel Corporation with headquarters in Toronto.

W. D. Ackworth, the financial expert of the commission inquiring into the Canadian railway situation, has arrived in Ottawa. Mr. Ackworth will assist A. H. Smith, chairman, and Sir Henry Drayton, in preparing a report.

Capt. John Trethewey, for many years recognized as one of the leading mining men in Canada, died after a long illness, in Toronto, on December 25. Captain Trethewey, who was in his 77th year, came to Toronto to reside when he retired from business ten years ago. Before that date he had lived for 20 years in Owen Sound.

John I. Reid has been made superintendent of the Longue Pointe plant of the Canadian Steel Foundries, Ltd., Montreal. He assumes his duties at once. He was formerly works manager of the American Steel Foundries' plant at Chester, Pa., and recently sales agent for the company at 30 Church Street, New York City.

Col. Thomas Cantley, president and general manager of the Nova Scotia Steel &Coal Co., has returned from a trip to England and France. He was away about seven weeks, a considerable part of the time being spent in France, his company having large contracts with the French Government.

Sub-Lieut. Andrew Dyas MacLean has been granted a commission in the Royal Naval Volunteer Service, and is at the present time taking a course at Greenwich. He is a son of Major Hugh C. MacLean, of the Hugh C. MacLean Publishing Co., Toronto and Winnipeg. The young officer went to England to join the motor-boat patrol service.

RAILWAYS AND BRIDGES

Edmonton, Alta.—J. D. McArthur, president of the Edmonton, Dunvegan, and British Columbia and allied railways, has stated that tenders had been invited for the big steel bridge across the Peace River, immediately north of the town of Peace River. It will cost a million dollars, and is to be ready in eighteen months.

MARINE

Montreal, Que.—Canadian Vickers, Ltd., are enlarging their shipbuilding plant at Maisonneuve, by adding a berth 500 x 128 feet and another 400 x 100 feet. This will provide for the construction of vessels of 12,000 tons.

TENDERS

Winnipeg, Man.—Tenders will be called until Feb. 12, 1917, for works required for the completion of the new Parliament Buildings which include the following. Heating and ventilating, electric conduit and wiring. Thos. H. Johnson, Minister of Public Works, Winnipeg.

Toronto, Ont.—Tenders will be received, addressed to the chairman, Board of Control, City Hall, Toronto, up to January 16, for the installation of a 40 million Imperial gallon centrifugal sewage pump at the main sewage pumping station, Toronto. Specifications and forms of tender may be obtained at the Works Department, Room 6, City Hall.

Ottawa, Ont.—Tenders will be received up to January 15, for the construction of a reinforced concrete lighthouse tower and fog alarm building combined, and a wooden dwelling at Point Abino, township of Bertie, Welland County, in the Province of Ontario. Plans, specifications, form of contract and schedule of wages, can be seen, and forms of tender procured, at the Department of Marine, Ottawa; at the Harbor Master's office, Toronto, and at the post offices, Welland, Port Colborne, St. Catharines, Bridgeburg, Hamilton and Brantford.

CONTRACTS

Vancouver, B.C.—The general contract for the construction of an extension to the C.P.R. Co's. Pier "D," has been let to S. E. Junkins and Co., Vancouver.

Toronto, Ont.—The Board of Education have awarded the following contracts in connection with additions to the Orde Street School. Metal roofing, D. M. Rowe & Co., $1,327; ornamental iron work, Canadian Ornamental Iron Co., $3,400; plumbing, Fred Armstrong Co., $6,095; heating and ventilation, Fred Armstrong Co., $6,890; heat regulators, Johnson Temperature Regulating Co., $826; electric wiring, Fred Armstrong Co., $640.

INCORPORATIONS

Dominion Iron & Wrecking Co. has been incorporated at Ottawa, with a capital of $50,000, to buy and sell steel, iron and scrap metals of all kinds, and to carry on the business of a wrecking company, with head office at Montreal.

The Canada Glass Works, Ltd., has been incorporated at Ottawa, with a capital of $250,000, to manufacture bottles, carboys, flasks, etc. The head office is at Toronto, and the incorporators are: H. P. Hill, A. C. Hill and S. F. MacDougall, all of Ottawa.

The Pembroke Machining Co. has been incorporated at Toronto, with a capital of $100,000, to establish and operate a machine shop and foundry at Pembroke, Ont. The provisional directors are: E. A. Dunlop, James F. Munro and Charles A. Eaton, all of Pembroke.

British Cordite Co. has been incorporated at Ottawa with a capital of $50,000, to manufacture cordite and explosives of all kinds, with head office at Montreal. The incorporators are: Walter R. L. Shanks, Francis G. Bush and George R. Drennan, all of Montreal.

International Magnesite, Ltd., has been incorporated at Ottawa, with a capital of $250,000, to manufacture magnesite, graphite, and other minerals. The head office is at Montreal, and the incorporators are: Leon Daoust, Aime Daoust, and Ernest D. White, all of Montreal.

The St. Louis Auto Machinery Co. has been incorporated at Ottawa, with a capital of $40,000, to manufacture automobiles, bicycles, and engines, etc., at Windsor, Ont. The incorporators are: Joseph B. St. Louis, Joseph F. Knight and Henry C. Cage, all of Windsor, Ont.

Port Arthur Copper Co. has been incorporated at Toronto, with a capital of $2,500,000, to acquire and develop mineral deposits, with head office at Toronto. The incorporators are: Arthur E. Way, William D. McKay and James H. Young, all of Toronto.

R. W. Stewart & Co. has been incorporated at Toronto, with a capital of $40,000, to manufacture paper specialties and boxes, etc., at Windsor, Ont. The provisional directors are: Robert W. Stewart and Richard Bangham, of Windsor; also Albert M. Draper, of Detroit, Mich.

The Northern Bolt, Screw & Wire Co. has been incorporated at Ottawa, with a capital of $500,000, to manufacture nails, bolts, nuts, screws, rivets, tacks, taps and dies at Owen Sound, Ont. The incorporators are: John McEwen, Clarence L. Vanwyck and James H. Van Overbeek, all of Owen Sound.

Capital Machinists & Founders, Ltd., has been incorporated at Ottawa, with a capital of $50,000, to carry on the business of machinists, engineers, brass and iron founders, etc. The head office is at Ottawa, and the incorporators are: Michael J. Skelly, Walter L. Goode, and E. P. McGill, all of Ottawa.

Metal Foundries of Canada, Ltd., has been incorporated at Ottawa, with a capital of $50,000, to develop mineral deposits and to carry on the business of smelting, refining, milling and foundry company. Head office is at Toronto, and the incorporators are: John M. Duff and James G. Hamilton, of Toronto.

The Wagner, Chambers, Glassco Co. has been incorporated at Ottawa, with a capital of $49,900, to carry on a general machine shop business and to manufacture munitions of all kinds. The head office is at Toronto, and the incorporators are: William E. Wagner, James L. Chambers, of Toronto, and Ernest S. Glassco, of Oakville, Ont.

FOR SALE

GAP LATHE, 28 x 42 x 16 FT. BED, FOR sale, cheap. Guarantee Motor Co., Hamilton, Canada. (4)

ENGINE FOR SALE—50 HORSE-POWER Corliss; no reasonable offer refused if taken at once. Box 387, Chatham, Ont. (2)

BROWN-BOGGS MARKING MACHINE FOR 4.5 shells. Has been used for short time only, and is in good condition. Box 248, Canadian Machinery. (24)

FOR SALE—1 ¼-1½ MODEL A CLEVELAND automatic screw machine. F. T. Coffin, 17 Tudor St., Cambridge, Mass., U.S.A. (2)

FOR SALE—75 H.P. CANADIAN GENERAL Electric motor, 25 cycle, 3 phase, 550 volts, 950 R.P.M.. In first-class condition. Box 258, Canadian Machinery. (26)

1 VERTICAL, SINGLE ACTION, DOUBLE cylinder hydraulic pump, 6" stroke, all ready to connect up; almost new; price $75. McGregor & McIntyre, 1139 Shaw Street, Toronto. (tf)

FOR SALE—FIFTEEN HEAVY CAST IRON columns, from thirteen to seventeen feet long. Columns tapered and have good heavy base and top. Also four roof trusses. Sixty feet long. Ten feet in centre, eight foot at ends. Will cut columns to suit purchaser. Woodside Bros., Port Arthur, Ont. (2)

1—2-SPINDLE SHAPER, WOOD TOP, JOHN Ballantyne, Preston, make, used two months. 1 Dynamo, 45 lights, Toronto and Hamilton Electric Co. make. Used five months. Good as new. Box 195, Jordon, Ont. (R.T.F.)

FOR SALE—1 40 H.P. ROBB, ARMSTRONG high-speed engine; 1 4 x 1 Marsh deep well steam pump, and 1 Barton generator, 80 lamp capacity, with switch-board. All in good order and cheap for quick sale. Richards-Wilcox Canadian Co., Ltd., London. (20)

FOR SALE—TWELVE H.P. GAS OR GASOline Engine. Goold, Shapley & Muir Ideal. In first-class condition. Cheap. Stedman Brothers, Ltd., Brantford, Ont. (21)

DOUBLE-END FEATHERSTONE AXLE cutting off machine with countershaft and equipment adapted for cutting off two 4.5 forgings at once. Bargain $500. Medicine Hat Pump & Brass Mfg. Co., Ltd., Medicine Hat, Alberta. (tf)

BAND SAW—COWAN & CO. MAKE, 30" Iron Frame. Post Machine 29½" x 33", Iron Tilting Table and Saw Guard, including Brazing Tools, setter for Filing, etc., has had very little use. Whaley, Royce & Co., Limited, 237 Yonge St., Toronto, Ont. (23)

SHRAPNEL SOCKET AND ADAPTER machinery, turret lathes, boring machines, cutting-off machines and thread millers tooled for operation. Globe Electric Machine Co., Hamilton. (tf)

FOR SALE, CHEAP—ONE TWENTY-TWO inch by ten-foot bed Porter lathe; compound rest, steady rest, set change gears, large and small face plate, eighteen-inch four-jaw chuck, boring bar, four tool holders and taper socket fitted. New Prague Flouring Mill Co., New Prague, Minn., U.S.A.

2—30 H.P. PRACTICALLY NEW, LATEST type Canadian General Electric Company's 30 H.P., 60 cycle, 550 volt, 3 phase, 900 R.P.M. Induction Motors, with starting compensators and adjustable sliding base, pulley 14", diameter 8" face. Price......$500 each f.o.b. Sarnia, Ont. 1—20 H.P. Same as above, pulley 11" diameter, 10" face. Price.........$390 f.o.b. Sarnia, Ont.

WANTED

WANTED—COMPLETE SET OF DRAWings or blue prints of Universal grinder, with all attachments. Box 251, Canadian Machinery. (1)

ONE AUTOMATIC SCREW MACHINE, capacity up to 1-in.; can use machine having had some service. Canadian Matthew-Gravity Carrier Co., 484 Richmond St. west, Toronto. (2)

WANTED—POWER-DRIVEN ROLLER 8' long, suitable to roll ¼" steel plates; state make, condition, time used. Give price and particulars to L'Air Liquide Society, corner First Ave. and Ernest St., Maisonneuve, Montreal.

WANTED—SMALL SCREW-CUTTING ENgine lathe 12" or 13" x 5' or 6' bed, automatic feed, power cross feed, compound rest; must be cheap and lathe in good working order; give full particulars in first letter. J. W. M., Suite 34, Thelmo Mansions, Burnett St., Winnipeg, Man. (24)

WANTED — THE FOLLOWING EQUIPment for 18-pr. H.E. shells:—2 electric or steam baking ovens, 2 painting machines, 1 banding press and pump, 2 band turning machines, 3 sensitive drills for drilling and tapping grub screw hole, 1 Bowser varnish pump, 1 marking machine. Send quotations to Box 253, Canadian Machinery. (24)

REPAIRING

ALL KINDS OF MACHINERY REPAIRED, rebuilt and installed. W. H. Sumbling Machinery Co., 643 Yonge Street, Toronto, Ont.

SITUATIONS WANTED

TOOL MAKER, ACCURATE, GOOD draughtsman, desires responsible position. Box 254, Canadian Machinery. (4)

SUPERINTENDENT, DESIROUS OF change, 18 pdr. shrapnel, and 6" H. E. shells. Box 247, Canadian Machinery. (26)

MECHANICAL ENGINEER, EXPERIenced in eighteen-pounders and six-inch nosed-in shells, with twelve years' drawing office, shop and general experience, will be disengaged shortly. Box 252, Canadian Machinery. (25)

EXPERT FOUNDRYMAN FAMILIAR with all modern foundry appliances, desires position as foreman or assistant in gray or malleable iron foundry. Box 250, Canadian Machinery. (25)

SUPERINTENDENT WITH PROVEN MEchanical and executive ability desires position as same, or one of equal grade. Wide experience with well known firms manufacturing high explosive shells, rifles, electrical machinery and instruments, light and heavy sheet metal and plate products. Have satisfactorily supervised installation and organized new plants for widely varied lines of product. Address P.O. Box 122, Dartmouth, Nova Scotia. (25)

SITUATIONS VACANT

TOOLMAKERS AND MECHANICS. APPLY Pease Foundry Co., Brampton; Junction 4341. (3)

WANTED—MAN TO TAKE CHARGE OF machine shop doing repair and new work. Must be up-to-date and able to show results. State experience and salary and when you can start. Apply Box No. 257, Canadian Machinery. (26)

FIRST CLASS GRIDLEY AUTOMATIC men wanted to set up Gridley automatic machines, also operators for same, highest wages paid, only first class mechanics need apply. Apply 47 Richmond St. East, Toronto. (24)

WANTED—NIGHT SUPERINTENDENT TO take charge of factory making 4.5 sockets. Apply Box 237, Canadian Machinery.

ALL-ROUND MACHINISTS WANTED FOR tool-room; highest wages paid. A. R. Ormsby Co., Limited, 48 Abell Strett, Toronto. (21)

WANTED — FIRST-CLASS MACHINIST able to take charge of our repair shop. Apply Hull Iron & Steel Foundries, Ltd., Hull, Que. (23)

MECHANICAL DRAUGHTSMAN WANTED for tracing and detailing on general machine work, also opening for man with experience on plate and structural work. Box 245 Canadian Machinery. (23)

SPLENDID OPPORTUNITY FOR YOUNG man about twenty-one, well educated and with some mechanical knowledge, who desires to learn the machinery business. Apply in first instance with full particulars as to experience, etc., to Box 243 Canadian Machinery.

WANTED—EXPERIENCED MILL WRIGHT and Machinist to take charge of construction and repair work in growing factory. A man who has had experience as foreman preferred. An excellent opportunity for a first-class man. State when you can start, also experience and salary wanted. Apply Box No. 256, Canadian Machinery. (26)

WANTED—EXPERIENCED MECHANICAL Draftsman; one who has had some experience on machine design and factory layout preferred. Apply stating experience and salary desired to the Goodyear Tire & Rubber Co., Bowmanville, Ont. (26)

WANTED — TECHNICAL ENGINEER — steady, energetic, practical, to learn the business and take charge of the operating and construction departments of a firm manufacturing compressed gases, and apparatus to use such gases. Reply giving experience and salary expected to Box No. 255, Canadian Machinery, 701 E.T. Bank Bldg, Montreal. (26)

INDEX TO ADVERTISERS

Machining the 4.5 in. Mark VII. Howitzer Shell

By A. F. Menzies *

Some better idea will perhaps be had of the scope of munitions manufacture within our borders when note is made of the fact that the accompanying article refers to the activities of a plant situated well-nigh to the extreme Western limit of this far-flung Dominion. Whether East be East, and West be West, in some realms of reasoning or its twin brother class imagination, it goes without saying that as far as meeting the insistent need of the hour is concerned, the aim and effort are as one, a condition likely to be permanent in its effect.

THE shop from which the following data were taken, relative to the machining of British 4.5 in. M. VII. H. E. shells, had been engaged for some time on an 18 pdr. H.E. contract, but, in common with other shops on the Pacific Coast changed over to the production of the larger size shells immediately the others were completed. The equipment used is all of standard type, except the cutting-off machine and bull-dozer, these together with all small tools and attachments, turrets, etc., having been designed and built on the premises. The shells are finished up to the riveting-in of the base-plates; banding, varnishing, etc., being done at a central plant which handles the output of a number of shops in the district. The capacity of the shop was estimated at 200 shells per day; at the time of writing, however, this output had not quite been reached. As every one engaged on munition work knows, it takes a little time to get machines and operators into line, and until everything is running smoothly, the maximum output cannot be expected.

The forgings, as received, are well enough known to omit description here. The first operation consists of the selection of forgings which are sufficiently concentric to be centered true with the hole. This is determined by the use of a wall caliper having two marks on the stem. Forgings which show no portion of the wall to be less than $\frac{3}{4}$ in. in thickness are passed along. Those which show occasional variation from $\frac{5}{8}$ in. to $\frac{3}{4}$ in. are piled separately and sent through in batches, care being taken at the centering drill that the center is shifted sufficiently to allow the forging to clean up both outside and inside. Forgings which show a wall thickness of less than $\frac{5}{8}$ ins. cannot be used. In justice to the inspectors at the forging shop, it should be stated that this class are rarely in evidence.

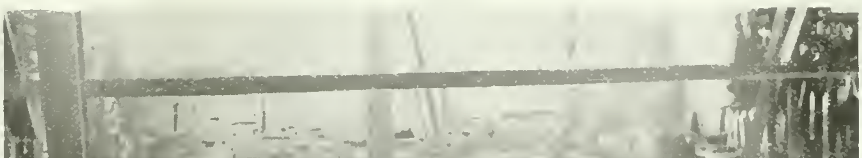

FIG. 1 LATHE IN WHICH SHELL BODIES ARE ROUGH TURNED

Open End Cutting-Off

The open end of the shell is trimmed in a cutting-off machine built for the purpose. The head consisted of a heavy iron casting carrying a hollow cast iron spindle running in babbitted bearings. The shell is slipped onto the spindle and secured by means of a set screw. To care for varying sizes of forgings, four set screws are located at 120 degs. from the locking screw; by properly adjusting these screws, the shells can be made to run absolutely true. As forgings of each heat number, and often of several heat numbers, are of practically the same size, adjustment is not often required. The head of the cutting-off machine is carried on a pair of I beams, which also carry the compound slide rest. The tool used is a piece of 3-16 in. x 2 in. high speed steel held in a special holder.

The location of the cut is found by a hook gauge which is so placed as to touch the bottom of the rough hole, the short leg forming a stop against which the parting tool is brought. A depth gauge is used to check the operator's work. The centreing was done on a Rockford Lathe & Drill Press Company's machine. The post over which the shell is placed has a hollow cone held up by a spring to centre the open end, while the base is brought true by a hardened cap on the upper end of the post. The post is carried on a swing table having a locating pin which enters a hole in the fixed table.

*Mechanical Engineer, New Westminster, B.C.

Rough Turning.

A 24-in. MacGregor-Gourlay lathe is used for the rough turning operation. This machine does its work in one cut, using two tools at a feed of 1-20 in. per revolution. Occasionally, with a shell that is much out of true or very hard, the feed has to be reduced. The back tool which leads and does the heaviest work, is of high speed steel, and is held in a cast iron arm bolted to the saddle. The front tool of ½ in. sq. stellite is gripped in a special holder in the tool post. The rough turned diameter of the shell is 4 9-16 ins., and the gauge used is of the ordinary snap type having limits .015 above and below the nominal size. The driving chuck on the rough-turn lathe is shown in Fig. 1., as are also the different tools. The chuck is of hardened tool steel, and has three cams formed on it. The cams force out hardened rollers to grip the inside of the shell.

The unused part of the long bed of the rough-turn lathe is used on which to mount a spare head and tail stock. These, with the addition of a compound rest built from the same patterns as that on the cutting-off machine, make a convenient apparatus for facing off the bases. This operation brings all the shells to the same over-all length, and, as the amount cut off the open end is gauged from the bottom of the hole, the base thickness is constant. Two drill presses are used to rough out the hole. The first, a 30-in. Baush machine, uses a bar with a single cutting tool which is fed down to where the hole begins to curve inwards. A spider guide, made to fit over the open end of the shell, forms a support for the bar. The other drill press, a 38-in. Niles machine rough forms the bottom with a forming tool held in a bar. A hardened sleeve made so as to just slip into the hole bored by the first drill press guides the bar. As the power feed cannot be used on some shells, a pointer is fixed to the bar to give the operator the correct depth of hole. A depth gauge is used to check the operation. On both drill presses the shells are held in hinged vises.

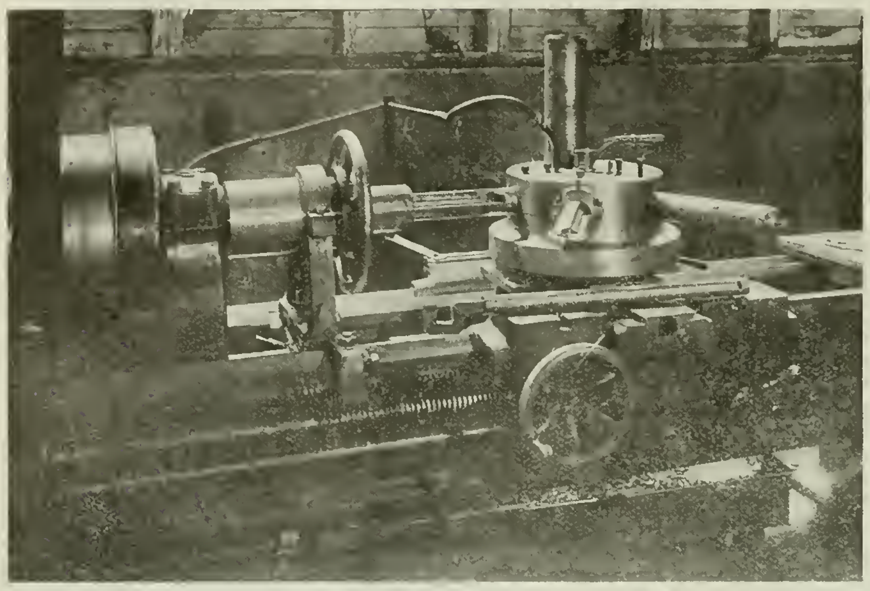

FIG. 2—FINISH MACHINING SHELL INTERIOR

Inside Finish

The inside finish, perhaps the most important operation on all H.E. shells, is done next. Two machines fitted with very heavy turrets are engaged on this work. The turrets are 16 ins. in diameter where the bars spring from, and have a 20-in. diameter bearing on which to swing. Fig. 2 shows one of the lathes on this operation. The shell on the turret shows the bevel on the outside of the open end. The beveling leaves a diameter of 4⅛ ins., and is carried back ⅜ ins. There are three boring bars, the first carrying point tool to true up the hole. The next, a rough bottoming cutter takes out all but a light shaving. The finishing cutter is run-in on power feed until almost at the bottom, when hand feeding is used to get a good smooth finish. The boring bars are of tool steel, fluted for the egress of chips. A ¼ in. brass pipe soldered into one flute carries the cutting compound to the business end. The second bar, in addition to its work on the hole faces off the end of the shell and forms the bevel. The tools for this work are held in a collar on the bar. The chucks used on this and on all subsequent chucking operations are of the collet type, having a cast iron body with forged steel jaws. The closing nuts which have the hand-wheels cast with them were to have been cast steel, but, by a mistake in the foundry, cast iron was substituted. So far, they give every evidence of standing up to their work. The chucks themselves have given every satisfaction, the hand wheels making them very convenient. The lathes used for the inside finish are both Le Blond products—one being 18 ins. and the other 24 ins. After the inside finish operation, the shells are examined for depth of hole, concentricity and smoothness of bore.

Nosing Operation.

Closing-in the noses constitutes the next operation. The shells are heated in an oil-fired furnace, constructed of steel plates and angles, and lined with Clayburn fire brick. No water jacket is provided and beyond a slight buckling of the front plate, no operation or other troubles have been experienced. The fuel used is crude oil delivered to the burners at from 35 to 40 lbs. pressure per sq. in., and at a temperature of about 225 degs. F. The oil is heated at starting by means of a Hauck kerosene torch directed on a coil of ¼ in. pipe through which the oil is passed. After getting under way, a water heater takes up the work. The latter is constructed on the same principle as a kitchen boiler. A reservoir made of 8-in. pipe containing a coil of ½-in. pipe made up of three lengths welded together, is con-

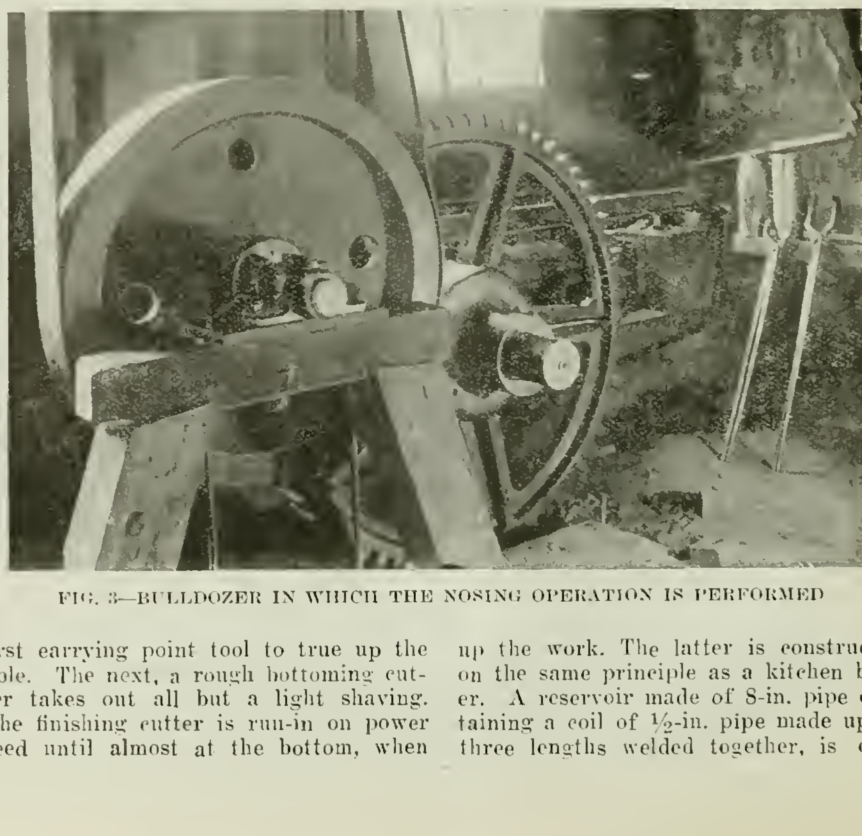

FIG. 3—BULLDOZER IN WHICH THE NOSING OPERATION IS PERFORMED

nected to the city water supply. A loop, starting from the bottom of the reservoir and passing twice across the top of the furnace, entering the reservoir again near the top, forms the heating surface. Air is supplied to the furnace at from 9 to 10 oz. pressure, by a Buffalo Blower & Forge Co. pressure blower. The oil

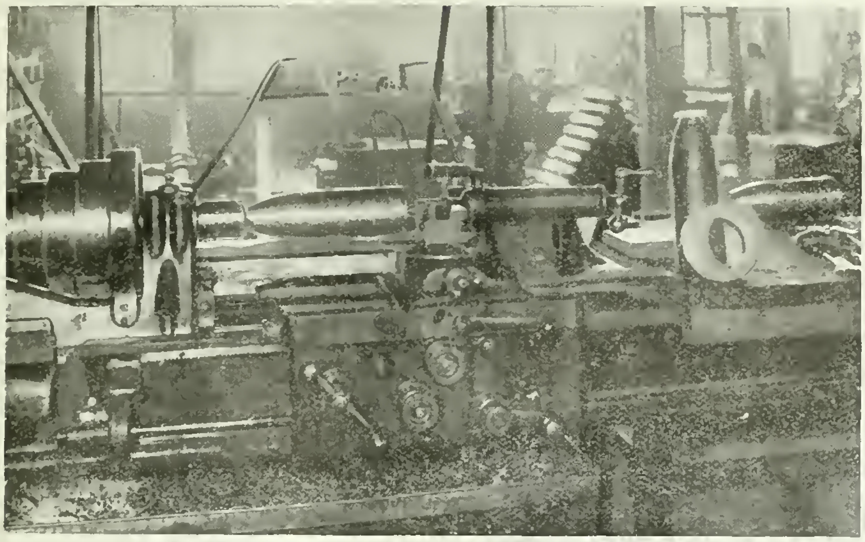

FIG. 4—FORMING SHELL BODY EXTERIOR PROFILE

burning equipment was installed under the supervision of E. C. Hogh, of the Machinery Installation Co., of Vancouver. The channel iron, on which the shells are seen standing in Fig. 3, runs along the front of the furnace and forms a table on which the shells are rolled to the bulldozer.

The nosing is done on the bulldozer shown in Fig. 3, the crank shaft of the latter being 6 ins. dia., with 7 ins. stroke. The dies used are of cast iron which seem to stand up to the work very well. After being closed-in, the shells are placed nose down in a galvanized iron pan containing about 8 ins. of mica. When cool enough to handle, they are examined to see that there is enough metal inside to clean up, and also for length. To judge whether a shell has sufficient metal inside or not requires not a little experience.

Finishing Inside of Nose.

The next machining operation is that on the inside of the nose. This is done on a 16-in. MacGregor-Gourlay lathe fitted with a chuck and a turret. The nose is first bored out below the fuse hole recess for the thread and neck. At the same time, a tool held in a collar on the reamer bar faces off the nose to the correct bevel. The inside profile is machined with two forming tools, one roughing-out and the other finishing. The tapping is done with a Murchey collapsible tap, after which the recess is put in with a tool mounted on an eccentric. To check the collapsible tap, an old 18 pdr. fuse hole gauge which had been lapped .003 in. small is used. The foregoing operations being found too much for one machine, the reaming, tapping and undercutting were removed to another lathe.

The shells are next tapped out to size by hand, and the fuse seat trued up with a special cutter. A centred plug is screwed into the fuse hole and the shell held betwen centres for turning the body and profile. A driver with a slot to take the lug on the plug, is screwed onto the headstock spindle. As two plugs are provided, the operator always has a shell ready to go into the machine which is an 18 in. American lathe. The tool, $\frac{3}{8}$ in. high speed steel is held in a block holder which can be moved in line with the lathe to bring the profile exactly right. A 2 ins. diameter roller secured to the cross slide, from which the screw had been removed, is held to the forming bar by a spring. The latter is supported by two cast iron brackets, one of which can be seen near the headstock, and can be moved in them by set screws transverseiy to the lathe, making a very convenient adjustment. A snap gauge is provided for the operator, the shells being examined for size with gauges also for shape of profile and for concentricity. Fig. 4 shows the profile lathe with a shell ready to be put in, the centred plug being clearly indicated, also the gauges used..

Copper Band Recess.

Cutting the upper band recess is the next operation. The lathe, a 16 ins. C. M. C. product to which a special attachment was added, the cross slide being removed, is shown in Fig. 5. The attachment fits the cross-slide ways and carries a roughing tool which operates on the under side of the shell, also two undercutting tools which operate at the back, and a waving tool at the front. The roughing tool operates by drawing the whole attachment toward the front by means of the cross slide screw. As this tool passes the centre and ceases cutting, a stop is encountered which locates the attachment to suit the undercutting tools. One revolution of the hand wheel A, feeds these tools in, and a spring returns them. The attachment is then returned to its first position against a stop located to suit the waving tool, and bringing the roller B in operation against the cam C, causing the wave tool holder to reciprocate. The hand-wheel D, feeds the tool into its work, a stop being provided to get the correct diameter. In this machine, the shell is held in a cup centre at the headstock, being driven by a pin engaging in a slot in the driver E, which is screwed into the fuse hole. To prevent the saddle shifting and altering the location of the band recess it is secured to the ways by a clamp at each side.

Forming Base Recess.

A 16-in. Le Blond lathe, shown in Fig. 6 is used to form the base recess, a square turret mounted on the cross slide carrying the tools. A hogging cutter is first fed into a stop, leaving a light cut to be taken off the bottom of the recess.

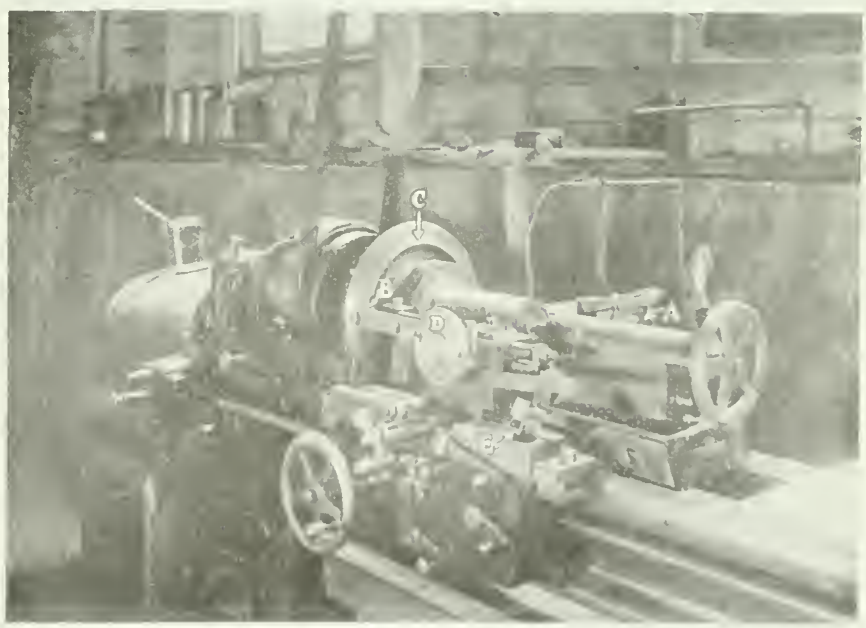

FIG.5—FORMING THE COPPER BAND GROOVE

While the saddle is held against the stop, the turret is drawn to the front to increase the diameter of the hole and also to bring into action a tool to face off the base and leave the riveting strip standing. The turret is next swung round and the tool shown in the illustration used to give the correct diameter and the perfect finish desired on the bottom of the recess. The shells are then ganged for base thickness, depth, and diameter of recess, the bottom being also carefully examined with a straight edge to see that it is perfectly flat.

Sand Blasting Shell Interior

Cleaning out the shells preparatory to sand blasting is rather a difficult job, but was solved finally by washing out with a jet of soda water and drying with rags on a stick. The sand blasting is done in a room made as nearly dust proof as possible. As a few grains of the steel shot, or sand left in the threads would prevent the screw gauge from going down, care has to be taken that the threads are properly cleaned out. A shield with a few threads on it was made up to screw into the fuse hole and effectually prevented the shot from getting into the threads. An elongated electric bulb with a tin shield half-way round it is used to examine the interior of the shell to see that the sand blasting has been properly done. A complete shop inspection, supplementary to that given after each operation, now takes place, and rectifications made before the shells are submitted to the Government examiners. Rectifications were made on a Boyes & Emmes lathe, fitted with various convenient attachments and tools.

Base Plate Machining

The lathe on which the base-plates are machined is a 14-in. Sebastian product. A chuck to hold the square shank is secured in the taper of the head-stock spindle. A square turret mounted on the cross slide carries the tools. A roughing tool made so that it can be used to rough-face as well as rough-turn the diameter is first employed. The turret is then swung round and a finish facing tool used, a very light cut with this tool resulting in a perfectly finished and flat base plate. A tool with a projection at 30 degs. on one side brings the diameter down to size, and also forms the bevel at the back of the plate.

The base-plates are riveted in by an air hammer, the shell being revolved in a converted pipe machine. A holder for the hammer is arranged so that it can be swung out of the way to take out and put in a shell. The holder also carries a stop which when the head is brought forward by the foot lever, holds the base-plate securely in the recess. The square shank of the base-plate is cut off in a Racine draw-cut hack saw, after which the shell base is faced off in a machine made by adding an old head-stock to the bed of one of the plant long lathes. A compound rest, to carry the tool, was also added. The tool is made of 7/8 in. square high speed steel, and is arranged to cut on the end to get under the scale and afterwards to cut on the side to remove the excess metal.

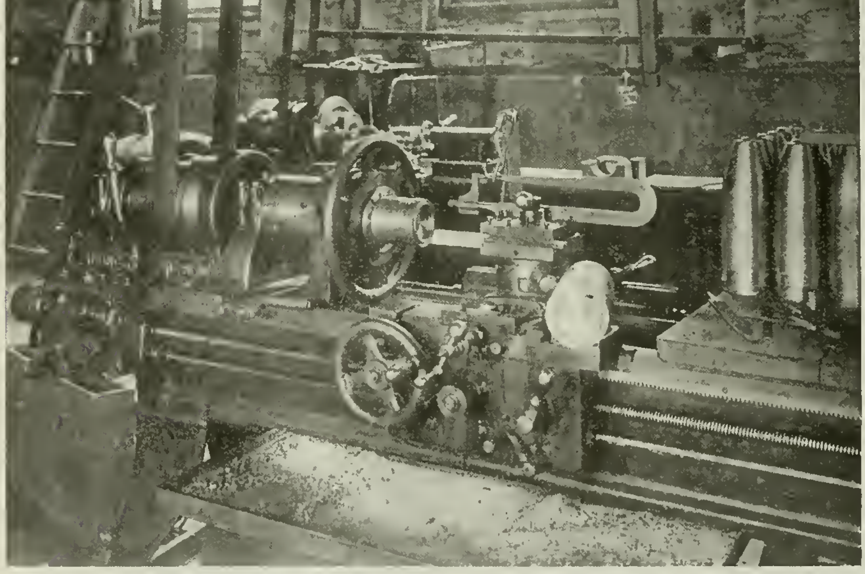

FIG. 6—FORMING THE BASE RECESS

The dimension limits for the distance from the base to the band recess being very small—about 1-32 in., care has to be taken not to remove too much. The weight, of course, has also to be watched. If a shell cannot be brought down to weight by removing metal from the base it is usually possible to get an ounce or two out of the inside profile. Care should be taken that the riveting is not cut away too much, this feature being due for consideration when determining the depth of the base recess. If the recess is deep enough there should be no fear of spoiling the work on this account.

The shells, before being passed into the inspection room, are weighed and the tightness of the base plates tested by tapping with a light hammer. Any shells which have the diameter of the base increased by the riveting are filed slightly to allow of the high diameter ring gauge to pass over.. On being accepted by the Government examiners, the shells are lightly oiled inside and out, packed into regulation boxes, in lots of three, and shipped to the finishing plant.

DOMINION STEEL CORPORATION YEAR

THE changed character of Canadian steel production is shown strikingly in the Dominion Steel Corporation output figures for 1916. In the calendar year of 1914 the rail output amounted to 176,505 tons. It was 174,802 tons in the fiscal year 1912-13. In 1915 the output fell to 57,500 tons, and last year it was 17,495 tons. On the other hand, the output of wire rods has risen successively from 30,778 in 1914, to 73,500 in 1915, and now to 112,400 tons for 1916, while sales of wire products, which were less than 11,000 tons in the fiscal year 1912-13, have jumped to 47,500 tons.

These increases are a direct reflection of the export demand created by war conditions, and have resulted from the corporation's ability to diversify its output. Last summer, President Workman noted that the mills were then turning out twice as much barbed wire as six months previously, and the production at the end of 1915 had been about double the capacity at the outbreak of the war. The rail production, now little more than nominal, suggests post-war developments for the life of a rail is only so long, and annual replacement demands alone, deferred to the fullest possible extent since the war, should furnish substantial business when urgent war requirements cease.

An official statement of the corporation's output for the calendar year 1916, shows a new record in tonnage of ingots, the figures being about 8 per cent. higher than in 1915. Pig iron production was more than 12 per cent. in excess of the previous year's showing. Coal output was lower at about 4,500,000 tons, against 5,000,000 in 1915, recruiting and the shortage of shipping facilities entering as adverse factors. The approximate output of the various products is given as follows:—

..	1916.	1915.	1914.
Pig iron	348,000	309,800	334,101
Steel ingots .	376,000	349,000	331,000
Rails	17,495	57,500	176,505
Wire rods ..	112,400	73,500	30,778
Wire products	47,500	34,000	32,414
Blooms, billets, etc. ..	150,000	....	....
Merch. bars .	9,950	....	....

Large expenditures were made during the year for improvements and extensions to the plant, as well as for renewals. The statement adds: "The tonnage of steel on order is sufficient to keep the works actively employed for several months, and, so far, there is no indication of any slackening in the demand for all the materials that the company can produce.

REMOVING THE MONOTONY OF REPETITION WORK

By J. W. G.

THAT the monotony of repetition has a seriously depressing effect on factory workers is a fact, which, until recently, did not receive due recognition nor ameliorative effort on the part of employers. Constant production of the same article on the same machine, or repeated performance of certain physical efforts in a limited manner, may enable the operator to become expert and capable of rapidly repeating the motions because of their increasing familiarity. But some day, sooner or later, depending on the person's temperament, there comes a realization of the dehumanizing effect of the work, and another man quits, sick of the job.

A Familiar Simile

That such a sequence of events is only human can be shown at once by considering the elementary development of a child. In learning to walk, for instance, the danger of falls and excitement of effort maintain an interestedness and induce further effort until ability is fully developed. Then what happens? As soon as effort is thoroughly familiarized and becomes unconscious, the child wants to walk, not for the pleasure of simply walking, but of getting somewhere. If its efforts are confined to walking round and round in a circle, how long will it continue before the novelty wears off?

And yet such a state of affairs is exactly parallel to the conditions toward which many factory occupations are leading those who will be led. The simpler the work and the fewer the actions necessary to its performance, the more certain is it that the activity of the brain is gradually lessened until the output reaches a flat level. This is the stage when accidents most frequently occur in operating stamp presses, etc. That such a state of affairs demands a remedy is obvious to any broad-minded student of industrial economics; but whether it is possible to find a real cure is not immediately apparent. It has been suggested by certain authorities that if more care were taken to explain to operators the purpose of their task and the part it plays in production, the tendency toward intellectual revolt would be checked, and the systems of shop education which have been established by several progressive firms are evidence of organized effort in this direction.

Recent Growth of Monotony

But it would be foolish for employers to imagine that the burden of unending monotony can be alleviated to any great extent by lectures or demonstrations regarding the purpose or use of parts made by the thousand. Motor car production is an outstanding example of the conditions under consideration. In the early days, when production was small and evolution rapid, every employee in a factory had a personal interest in new models, and the numerous and sometimes radical changes in design maintained a spirit of expectancy among the workers which lasted from season to season; but the commercialization of the industry has removed the fascination of novelty and substituted the problem of production. While esprit de corps may have a stimulating effect in factories producing cars of particular reputation, the number of factories making component parts lack this feature in their output, and the probability of removing monotony there is just as remote as in the case of making tacks or punching links for chain belts. In none of these cases is the operators' state of mind likely to become more composed toward the work if the functions of a steering gear or a piston pin are explained in relation to a complete car; tacks are too commonplace and chain belt parts possess about as much individual interest as a brass time check.

Complete Removal Impossible

The present flood of shell production has called many workers who never handled a machine in their life, and, after some time, familiarity with the product induces an indifference which is only kept in check by rigid inspection of product. The stimulus of personal interest in the course of hostilities is present with many of the workers, but lacks the permanent persuasion offered by adequate remuneration. When all is said and done, the prime object of labor is to earn an existence and the amount of cold cash earned represents the degree of existence enjoyed, which is just what most individuals are most concerned about.

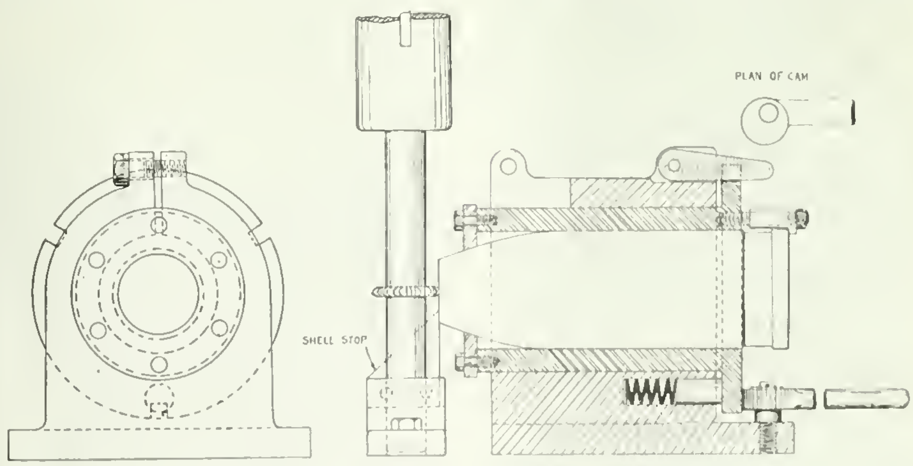
No amount of moralizing will alter the fact that the monotony of repetition work cannot be removed. Education will either irritate, so that the operator will eliminate himself, or else induce him to become reconciled to fate; automatic machines may partly remove it, but, in the final analysis, the greatest comfort will be derived from the pay envelope. Drudgery will always be with us, and until some unforeseen change in conditions takes place, the stultifying effect of repetition work on operatives' intelligence can best be counteracted by giving them the means and opportunity of obtaining suitable counter-irritants or salves, free from factory influences or any taint of commercialized sympathy.

NICKING ATTACHMENT FOR SHELL NOSES

By A. F. White.

THE attachment shown in the accompanying sketch is designed for cutting the nicks in the nose of 4.5-in. Mark VII. shells. It can be used equally well in milling machine, drill press, or small lathe, the sketch showing it in a drill press.

The cutter arbor is driven by the drill spindle, the lower end of the arbor being carried in a steady bearing bolted to table. The shell is carried in a revolving sleeve, the end next the cutter having a ring bolted on for supporting the shell nose, and the opposite end flanged and provided with three slots for spacing the nicks. The shell is held in the sleeve by a tubular clamp carried on a stud, and is fed against the cutter by sliding the sleeve in the main casting by means of a levered cam mounted on the base and working against the side of the flange.



NICKING ATTACHMENT FOR SHELL NOSES

After milling each nick, the sleeve is

backed out by a spring plunger working against the inner face of flange, after which the locking plate is disengaged and the sleeve revolved by hand to the next position. The depth of nick is controlled by a stop-plate, carried by the arbor support, against which the shell nose makes contact. The main casting is bored a close fit for the sleeve and is split at the nose-end to allow of tightening up for wear and removing all shake.

The manner of using this attachment in lathes and millers is sufficiently obvious, the arbor being mounted horizontally and the main casting carried on the miller table or mounted on cross-slide of lathe.

OVER-MUCH DRILLING EFFICIENCY

By R. Hamilton.

ALL through the ages the question of efficiency, often more or less disguised, has been the bane of many a man's existence. During my apprenticeship in a large railroad repair shop, at a time when twist drills especially of the larger sizes, were considered more of a luxury than at present, the greater amount of heavy drilling being accomplished by means of flat drills. I recall an experience of "high speed" drilling that would appear to put the methods of today somewhat in the shade. The work consisted of drilling seven or more $1\frac{1}{8}$ inch holes in air-brake fork levers, using a block of wood between the two sections.

With a large pile of these on the floor, I was making satisfactory progress, operating the drill at the slowest speed of about 80 or 90 revolutions per minute, with a fair feed when the shop foreman came along, stood for a few minutes looking at the pile on the floor and the action of the drill alternately. Seeing the master mechanic coming down the shop, he suggested that I "throw her up" on the next speed. Without comment I did so, and with a partially concealed smile he walked away, only, however, to be replaced by the master mechanic, a moment or two later. He ,after a brief survey of the situation, asked if the drill could not be run on a higher speed. I said it could, but did not think the drill would stand it. He pooh-poohed the idea, and further suggested that I again increase. Almost immediately thereafter, he told me to keep it there and proceeded on his way: just like some bosses who jump into a hole and throw clouds of dirt out in an effort to demonstrate to the operator how he should work, with no apparent realization that what may be possible for a short time is impracticable for an extended period. So, in this instance, with a sharp drill, lots of lubricant, and increased speed, the output for the moment, so to speak, contributed to the greater efficiency achievement impression with which the master mechanic had disappeared from the scene.

The duration of the "test," however, was well within the time required to drill two complete holes, and it was no suprise to me that the drill needed grinding before starting the third hole, and that, after finishing two more, the size of the drill had been destroyed. This of course necessitated a trip to the blacksmith shop for redressing and tempering the drill, which after drilling six or eight holes required to be repeated.

On returning from one of these journeys to the "adjusting bureau" the foreman was waiting at the machine to inquire of my progress. Upon learning that the output had decreased over 50 per cent., owing to the extra time spent at the grindstone and tool dresser, he started to "call" me for not reducing the speed, but I suggested that his remarks be reserved for the "chief", as I was only obeying his orders. This, resulted in closer attention being given to the details of operation, and after several demonstrations, the original speed was decided on with a slight increase in the feed, which goes to show that speed is only one of the factors in the problem, and its elimination often aids in solutions for economic efficiency.

A BELGIAN BALL-TEST MACHINE

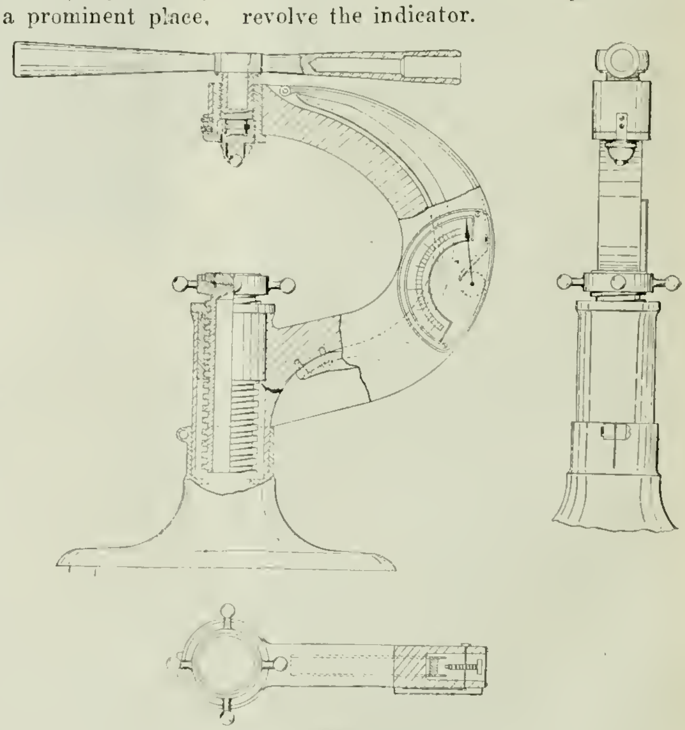
By J. W. G.

THAT increasing recognition is being given to that quality in metals generally termed hardness is evidenced by the number of machines which are now available for testing purposes. Among the different methods in use, the ball test has always occupied a prominent place, the Brinnell system being a standard for certain classes of work. This fact, together with the present terrible tragedy in Belgium, imparts a peculiar, almost a morbid interest to the device illustrated herewith.

In pre-war days an international reputation as a producer of the highest grade of forgings was enjoyed by the Usines G. Derihor Societe Anonyme, Loncin (Lez-Liege), and the ball testing machine illustrated herewith was developed in the Derihon shops and used in their work regularly. The writer first saw this machine about seven years ago and feels that the peculiar features of the machine, coupled with changed conditions, make it of special interest to your readers at this time.

The method of operation consisted in pressing a 10 mm. hardened steel ball into a specimen of the material, and measuring the diameter of the impression on different specimens of the same material. The frame of the machine was a hook-shaped forging of narrow channel section, the lower end terminating in a large boss containing an elevating screw for the table, while the upper end carried a pressure screw and testing ball. When pressure was applied to the ball, through the double-ended wrench on top of pressure screw, the resultant stress caused the gap in the frame to open, the frame being so designed and proportioned that regular increments in load were accompanied by equal amounts of distension in the frame without the stresses being near enough the elastic limit to affect its permanent resistance. In other words the frame acted as a very strong spring.

The amount of deformation imparted to the frame was indicated by a simple lever and pinion arrangement shown clearly in the illustration. A small channel section member was fastened to the base of frame, fitting the curve to a point near the pressure screw. Here the member terminated, a knife edge being formed on the end to support a hinged member which carried a rack at its lower end, this rack engaging with a pinion on the indicator spindle. As the bending of the frame took place above the point where the small channel member was attached, relative movement between their upper extremities ensued, so that the hinged member descended as its hinged end was raised, allowing the rack to travel across the pinion and revolve the indicator.



BELGIAN BALL TEST MACHINE.

The diameters of impressions were measured by a glass gauge similar to a wire gauge. By carefully observing the contact of the tapered lines with the edge of impression, an empirical number was obtained which could be referred to any other specimen provided the same pressure was used in making the test. The maximum pressure applied varied with different materials, the chief point being to get a medium sized impression where possible without injuring the work unnecessarily. Where standard grades of material were in constant use, suitable pressures were specified so that measurements with the scale were then comparable.

To the writer's knowledge, these machines were at one time on the market in the United States. Many dark days have passed over its land of origin since then, the Derihon factory at one time being reported in operation under German control; recent developments, however, create considerable misapprehension regarding the men and plant who were responsible for the development of the machine.

HUMAN FACTOR IN THE WORKSHOP

By J. Wright.

PRESENT-DAY competition has become so keen that the scientific and mechanical world are working at high pressure devising ways and means to increase the quality and quantity of manufacturing output at a minimum expenditure, both of money and material. It is only within the past few years, however, that any great amount of consideration has been given the general betterment of conditions under which employees operate in industrial establishments. It is encouraging, however, to note that the value of the human element is being more and more appreciated at its true value.

There was a time when the average workman was for the most part recognized as simply a piece of machinery, capable of working long hours and under almost any conditions. Many things have transpired to prove the fallacy of such a belief, with the result that employers are giving more attention to the welfare of their help than ever before. Progress in this direction has not only proved beneficial to the workmen, but results have shown that a higher standard of production is maintained in those factories where the environment tends to the "uplift" rather than the "depress," the latter of which is more or less associated with dismal and unsanitary surroundings.

Examples might be cited where material gain was falsely considered of more importance than the health or welfare of the employee. Some years ago on a certain machine, the "boss" had considerable difficulty in keeping it in continual operation owing to the irregular attendance of the operator, who was absent quite often as a result of contracting heavy colds, due to the draught created by the opening of a nearby door. A screen was suggested, but nothing was done until the season arrived when artificial light was necessary. The open gas jet could not protest against the draught, but, as the light was essential, a screen was erected to "protect the light," and thus provide a better opportunity for the man to work.

On another occasion the superintendent was showing a visitor about the works, and happened through the galvanizing department at a time when some tanks were being supplied with fresh acid. The visitor lost no time in seeking the freer atmosphere of the adjoining room, remarking to his host that he would not work in such a place for $20 a day. The boss replied that "the men did not mind it; in fact, they actually eat the stuff." This was probably true, and they were doing it for much less than $20 a day, or even a week, while in reality the fumes from the acid were slowly consuming them as the days rolled by. However, not long after this visit facilities were provided to aid in carrying off the poisonous fumes and permitting healthier working conditions for the employees.

When more thought is given to the efficiency of the workmen through the agency of the human touch, by incorporating suitable and sanitary environment with that of their daily tasks, the ever present problem of shop efficiency will become less complex.

THREAD INDICATORS

THE little device often found on lathe saddles and on some screwing machines, variously known as the thread indicator, pitch indicator or dial indicator, is an extremely useful arrangement if used intelligently. Owing to the large number of untrained workers now operating, or being taught to operate, machine tools, it may not be out of place if we endeavor in what follows to explain the principle and use of this indicator, thus substituting understanding for rule of thumb.

If anyone desires to make the device, it is a simple matter to attach it to the machine. Fig. 1 shows the indicator as fitted to a Lodge & Shipley lathe. A hole is drilled underneath the wing of the

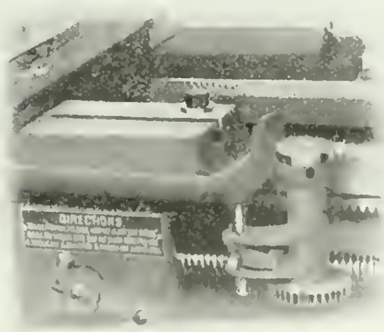


FIG. 1

saddle and a turned pin fitted in it. The bracket which carries the worm wheel and dial is free to swing on this pin; it is, however, kept by spring pressure with the worm wheel, in mesh with the lead screw. This spring pressure is furnished by means of the finger seen beneath the two arms of the bracket. This finger is locked on the pin by a set screw and a small helical spring is fitted between its end and the bracket. The worm wheel should have teeth of the same pitch as the lead screw, while the number of teeth should be a multiple of the number of

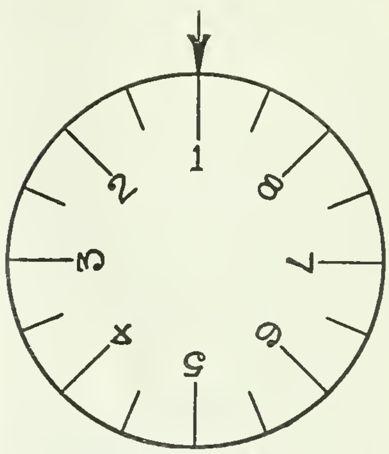

FIG. 2—THE DIAL SHOWING 8 NUMBERED AND 8 UNNUMBERED GRADUATIONS

divisions on the dial depending on the pitch of the lead screw. Examples:—

Pitch of Lead Screw.	Divisions Dial.	Teeth in Worm Wheel.
2 thds. per in.	8 or 16	16 or 32
4 thds. per in.	16	32
6 thds. per in.	16	48

The dial and worm wheel must be connected in such a way that, when the half nuts are engaged, a graduation on the dial must be opposite the index mark or pointer. When using the indicator, the saddle can be run back by hand and the half nuts re-engaged at the proper point without fear of cross-threading. Its use entirely obviates the necessity for a reversing countershaft or for the old-fashioned method of chalking the work and the lead screw. In principle, the thread indicator is a device for showing the operator when the work and the lead screw are in register one with the other.

Each revolution of the lead screw when the half nuts are disengaged causes the worm wheel to rotate one tooth—that is, provided the lead screw is single threaded, which most of them are. Each division of the dial corresponds to a certain number of teeth in the worm wheel. Assuming that the dial is graduated as Fig. 2, then the number of teeth of the worm wheel, and consequently the number of revolutions of the lead screw, that will cause the dial to rotate one division, will be as follows:—

Teeth in Worm Wheel.	Revs. of Lead Screw to Make Dial Rotate One Division.
16	1
32	2
48	3

When the screw-cutting tool is taking the first cut over the work, everything is in register. If that register is disturbed, as it is by disengaging the half nuts at the end of the cut, the half nuts must only be re-engaged for commencing another cut when everything is in register again. This will only occur when both work and lead screw have made a whole number of revolutions in the same ratio as the number of threads per inch being cut and the number of threads per inch of the lead screw. For instance, if cutting, say, 14 threads per inch, and the lead screw has 4 threads per inch, then, from being in register to coming in register again, the work must make seven complete turns to two of the lead screw, these being the smallest whole numbers in the ratio of 14 and 4. If cutting, say, $11\frac{1}{2}$ threads per inch, then work and lead screw must make 23 and 8 revolutions respectively before all is in register again.

The reason for this is the fact that work and lead screw are geared in the same ratio. Imagine an unthreaded piece of work in the lathe and a pointed tool in contact with it. If the machine is started with the half nuts engaged, the tool marks a path on the work, this path being an incipient screw thread. Next imagine the machine at rest, the tool touching some point on the marked path and the half nuts engaged. Everything is in register.

If now we disengage the half nuts and revolve the lathe face-plate by hand, we find that the work and the lead screw have to make a certain number of revolutions before they are in register again—the revolutions made will be in the ratio of the threads per inch on work and lead screw. While all this is being done, it will be noted that the dial is also rotating, and register is obtained when a division mark is opposite the pointer. If we repeat the operation, we shall find register again occurring with a division mark opposite the pointer.

Next let us imagine some specific numbers of threads to cut and carry out this operation, noting the division marks opposite the pointer each time register is obtained. It is assumed that the dial is graduated as in Fig. 2, and the following factors hold good. There may be exceptions, but they do not affect the principle, and they will be few and far between.

Thds. per in. of Lead Screw.	Teeth in Worm Wheel	Rev. of Lead Screw to make Dial Rotate one Division
2	16	1
4	32	2
6	48	3

First, take an even number of threads per inch to be cut on the work. Register is obtained when the work has made the same number of revolutions as the threads per inch. At the same time the lead screw will have made two, four or six revolutions, according to its pitch. As all even numbers are divisible by two, register is obtained when the lead screw has made either one, two or three revolutions, which, according to the table above, occurs when any division mark comes opposite the pointer. Therefore, when cutting an even number of threads per inch, the half nuts can be engaged when any division mark is opposite the pointer.

Next take an odd number of threads per inch. As such a number is not divisible by two, register is only obtained when the work and lead screw have made the same number of revolutions as their respective threads per inch. That is, the lead screw must make either two, four or six revolutions, according to its pitch. Therefore, when cutting any odd number of threads per inch, the half nuts can be engaged when any numbered division is opposite the pointer.

Fractional threads are those including a fraction along with a whole number in the number of threads per inch, as, for instance, $11\frac{1}{2}$, $2\frac{1}{4}$, and so on. These numbers must be multiplied by the denominator of the fraction to bring them to the lowest whole number of revolutions that the work must make before register is obtained. Half threads must be multiplied by two; so also with the threads per inch of the lead screw. Therefore, when cutting threads, including $\frac{1}{2}$ in the number of threads per inch, the half nuts can be engaged when the dial has made a quarter revolution.

Quarter threads require multiplying by four; so also with the threads per inch of the lead screw. Therefore, when cutting threads including $\frac{1}{4}$ in the number of threads per inch, the half nuts can be engaged when the dial has made a half revolution.

It is wise when commencing to cut fractional threads to see that the dial has a numbered graduation opposite the pointer, as this makes it easier to reckon the half and quarter revolutions. When we have to cut threads involving some odd fraction in their number per inch, such as 14.083, then the dial indicator is of much less value. The only way is to mark the work at the end where cutting starts, and to only engage the half nuts when the mark and, say, the number one graduation come in register at the same time.— *Herbert's Monthly.*

CANADA'S 1916 COAL OUTPUT

THE Dominion Department of Mines has received from the principal coal operators in Canada returns of their production for ten months, supplemented in most cases with estimates for November and December.

On the basis of the record available, it is estimated that the total production of coal in Canada during the calendar year 1916 will approximate 14,365,000 short tons (equivalent to 12,825,892 gross tons). The estimate is believed to be fairly close for Nova Scotia and British Columbia. In Alberta, however, there are so many small operators that final returns may show a wider variation from the estimates now made. By provinces the estimate is as follows, the figures for 1915 being included for comparison:

	1915.	1916.	Inc.
N.S.	7,463,370	6,950,000	*513,370
N.B.	127,391	135,000	7,609
Sask.	240,107	260,000	19,893
Alberta	3,360,818	4,400,000	1,039,182
B. Columbia..	2,065,613	2,620,000	554,387
Yukon	9,724	......	......
Total	13,267,023	14,365,000	1,097,977

*Decrease.

The 1916 production exceeds that of the two previous years, the increase over 1915 being about 8 per cent. Nova Scotia is apparently the only province that has not made an increased production, the falling off in this province being a little less than 8 per cent. The increase in Alberta is nearly 32 per cent., and in British Columbia nearly 27 per cent. The production in New Brunswick, Saskatchewan and British Columbia is the highest on record. No estimates are available yet as to the Yukon output.

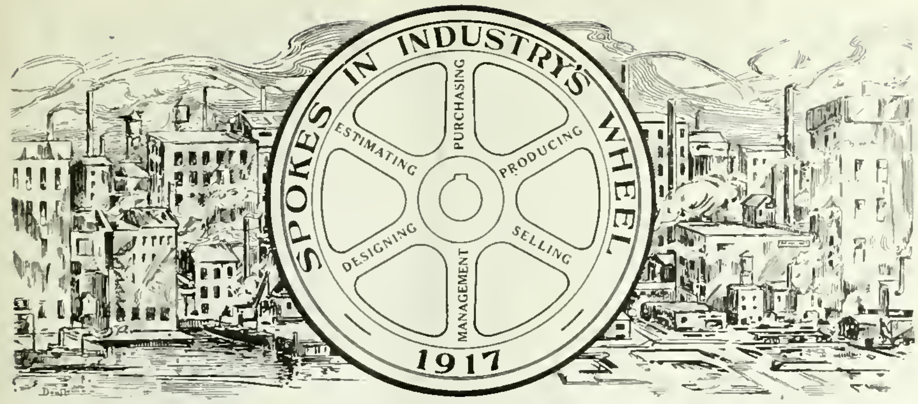
CONCERNING SUPPLIES FROM UNITED KINGDOM

MERCHANTS, manufacturers, and the general public are urgently requested to refrain from applying for permission to obtain materials and supplies from the United Kingdom, unless the same are required for war or other urgent national objects. It is essential that supplies in the United Kingdom should be conserved for direct war work and work of urgent national importance.

So runs a notice issued to Canadian manufacturers and others by the Trade and Commerce Department, Ottawa. It brings to light the fact that the restriction of export of a large number of articles by the British authorities has become a matter of serious import to Canadian trade, and the work of seeing that necessary exceptions are made to the general restriction in favor of national importance in the Dominion is keeping the Trade and Commerce Department busy. On the restricted list are commodities such as tin plate, tin sheets, wire rope, boilers, machinery parts, tool steel, hoisting cable, etc. A number of these are articles directly, and in other cases indirectly, required in the manufacture of munitions, so that every effort is being made to see that Canada obtains enough for such requirements.

In connection with all applications to receive shipments from the United Kingdom of goods on the British export restriction list, there is now being required detailed information as to the nature of the goods and their purpose. Such information includes:—Names and addresses of exporter, Canadian consignee and actual user of goods; quantity and descriptions; purposes for which required; whether or not goods might be substituted; why the goods required could not be purchased in Canada or the United States; degree and proof of urgency and consequences should application be refused; if goods are for stock purposes what is normal stock; stock on hand; average call on stock per month; stock it is desired to hold. When such information is furnished to the Trade and Commerce Department, the latter requests the Canadian High Commissioner in London to support the exporter's application for the issue of a priority certificate by the Minister of Munitions which is a necessary step before export licenses may be issued by the War Trade Department at its discretion.

Representations have been made to the Trade and Commerce Department with particular relation to the import from Great Britain of wire rope. The restriction of its export has been particularly felt by the lumber and mining industries of British Columbia.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

JOHN SHARP

THE war-created prominence accorded shipbuilding and marine engineering on this North American continent has had the specific effect—and more especially in Canada—of bringing into the limelight a section of the industrial community, who, from lack of demand for their handicraft, had been, if not altogether outside the pale of nation builders, at most but contributory in much restricted degree. John Sharp, chief engineer, Polson Iron Works, Toronto, Ont., is of the number. His firm, in common with others recently or long established, have not only their every available shipbuilding berth filled with ocean-going freighters in varying stages of construction, but carry on their books a sheaf of contracts for vessels of a like type, calling for earliest possible delivery, and, making necessary as a result, plant extensions ranging all the way from 100 to 200 per cent. normal or prewar capacity.

John Sharp—what the name lacks in ornamentation it expresses in keenness, relative to personality or otherwise—was born at Brantford, Ont., May 26, 1886, of Canadian-by-birth parents—Benjamin and Rachel (Near) Sharp, who, it may be stated, also first saw the light under our Dominion sky. He received his education in the public and high schools of his native city, following which, during the years 1902-1906, he served a four years' apprenticeship in the draughting office of the Waterous Engine Works. In the latter year he joined the engineering staff of the Dyment Foundry Co., of Barrie, as chief draughtsman, occupying that position until associating himself with the Canada Foundry Co., Toronto (now Canadian Allis-Chalmers Co.), in 1908. The variety experience gained in the plants above enumerated laid, as it were, the foundation for not only an enlargement of the scope of John Sharp's general mechanical engineering bent, but developed both his inquisitiveness and acquisitiveness relative to other fields of metal-working activity.

In 1910, therefore, we find him transfer his services from the Canada Foundry Co. to the engineering department of the Polson Iron Works, and here it may be in order to say that, with his promotion to the post of chief engineer of the latter concern some four years ago, he has found opportunity for the exercise of his skill in a specific class of product to which his endowment of talents has been naturally adapted. The manufacturing output of the Polson Iron Works covers a wide range, embracing as it does general mechanical, steam, and marine

JOHN SHARP

engineering, shipbuilding and ship-repairing, and, when it is remembered that John Sharp's experience previous to 1910 was largely, if not altogether, confined to engineering equipment for ashore service, much credit is due him for the apt—*sharp*, if you like, way he has in these recent years appropriated to himself an honored place among Canada's naval architects and marine engine and boiler designers. With the practical certainty of a decade of more or less abnormal activity in shipbuilding and marine engineering within our borders, his star with respect to same is likely to continue in the ascendant.

Mr. Sharp is unmarried, although quite as eligible to pass from that state to the other as to develop into a naval architect from eight years' experience as a mechanical engineer; besides, and judging from his devotion to his chosen and adopted craft and calling, there is little doubt but that a like disposition would mark his matrimonial enterprise, and, therefore, in course its equal success. We might say that in the few brief moments during which the more personal data connected with this career sketch were being acquired, our single or married query brought out the information—single [at present], the words in brackets being, however, hastily withdrawn. The outlook, needless to say, gives promise of a thinning out of the ranks of bachelordom at an early date.

In politics, Mr. Sharp says he is Independent, which, in nine cases out of ten as regards the engineering fraternity generally, means that little or no interest is taken—lack of time, and little or nothing in common, being good and sufficient reason for not taking sides. In religious creed he is Anglican—engineers are usually found associated with progress and uplift, and, therefore, belong to one or other church denomination. In matters military, he holds a commission in the 12th Regiment, York Rangers, a circumstance by no means surprising when account is taken of the prominent part that engineering of every kind is playing in this great European war. He had as a matter of fact enlisted for Overseas Service and had quit his work, but because of the equally important duty of helping to eliminate the shipping shortage, his recall was officially ordered. He is a member of the A.F. and A.M., the Engineers' Club, Toronto, and of the Society of Naval Architects and Marine Engineers, New York. His residence is at 121 Carlton Street, Toronto.

"The engineering profession," says Mr. Sharp, "embracing as it does so many branches and departments, presents a variety of opportunity to every young engineer or mechanic who cherishes the desire to advance. He should, therefore, concentrate both his studies and his energies along one line until that is mastered, both in theory and practice. Present-day educational facilities—technical schools, technical and trade papers, technical and practical text books, are available and within easy reach, furnishing reliable stepping stones to position after position of advantage, regardless of initial circumstances or vagaries of environment."

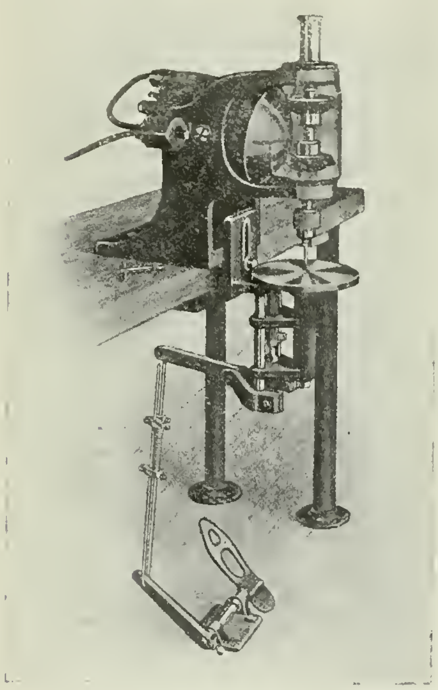
Phosphorus is considered by many brassworkers to be the only deoxidant of value in dealing with copper alloys. It is, however, frequently added to excess, when it become injurious. A proportion of 0.25 per cent. is the maximum permissible while 0.10 to 0.15 per cent. is ample for all ordinary purposes.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

MOTOR DRIVEN TAPPING MACHINE

IN constructing the tapping machine illustrated herewith, the designers had as their object a high-grade tapping machine in which the cutting speed can be varied without affecting the time per operation, that is, having increased reverse speeds to compensate for slower cutting speeds, conjointly with this being an efficient type of motor drive which would transmit a maximum amount of power so that the machine might be run on ordinary lighting service wire without undue overload.



MOTOR DRIVEN BENCH TRAPPING MACHINE.

The machine is of the vertical drill press type, having a high carbon steel spindle mounted in ball bearings top and bottom, the inner ball races, in which the spindle moves endwise, being increased in length by pressed-in sleeves, fitted very accurately to the ground spindle. An enclosed spring balance is fitted to the upper end of the spindle, adjustment being provided to suit the weight of the spindle and related parts.

Friction drive is employed between the motor and spindle, a spherical disc being mounted on the end of the motor shaft, and engaging with the convex edge of two friction discs on the spindle. As a result of the curved line of contact obtained by this arrangement the tendency to slip is largely reduced. The motor is pivoted in the frame of the machine on the same centre as the spherical friction disc, so that by tilting the motor, various cutting and return speeds can be secured, any decrease in one direction resulting in a corresponding increase in the other.

The circular work table is 7 in. dia. and has a vertical movement of $1\frac{3}{4}$ in., being guided by two way-rods which can be adjusted vertically 3 in. A balance spring below the table makes the movement of the tap very sensitive when doing small work. The table is operated by foot treadle, a safety spring being fitted to prevent spoilt work through too sudden pressure on the treadle. The lower part of the table is hollow and acts as a lubricating well, the taps dipping in and being cleaned at each stroke of the table.

This machine is built by the Anderson Die Machine Co., Bridgeport, Conn., and is distributed in Canada by the R. E. T. Pringle Co., Toronto. The net weight is 115 lbs., and it has a capacity with standard taps of 1-16 in. to $\frac{1}{4}$ in. in cast iron, 1-16 in. to 3-16 in. in steel, with a depth of $1\frac{1}{2}$ in.

SINGLE PURPOSE HIGH SPEED DRILLING MACHINE

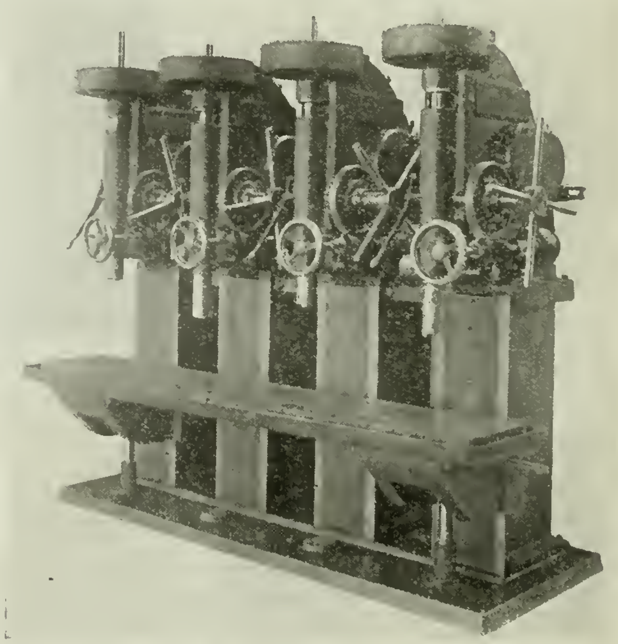
THE heavy vertical drilling machine illustrated in the accompanying cuts is intended for single purpose manufacturing work to drive $1\frac{1}{2}$ in. high speed drills to the limit of their efficiency in steel. Simplicity of design and rigidity of construction characterize this machine, which, while built for quantity production, is capable of performing a wide range of work with little change.

The frame is of the two-piece type, the lower or column portion having its front face machined to take the eelvating table which is gibbed thereto. The upper or headstock portion is securely bolted to the column and carries all the driving gear and feed mechanism. The spindle is machined from a high carbon steel forging, having a No. 5 Morse taper hole in the nose, which is slotted across for driving heavy boring and facing tools. The sleeve which carries the spindle is supported in bearings for its entire length, and is fed by hardened nickel steel rack and pinion, the worm gear on the pinion shaft being fitted with a safety shear pin to protect the feed mechanism from overload.

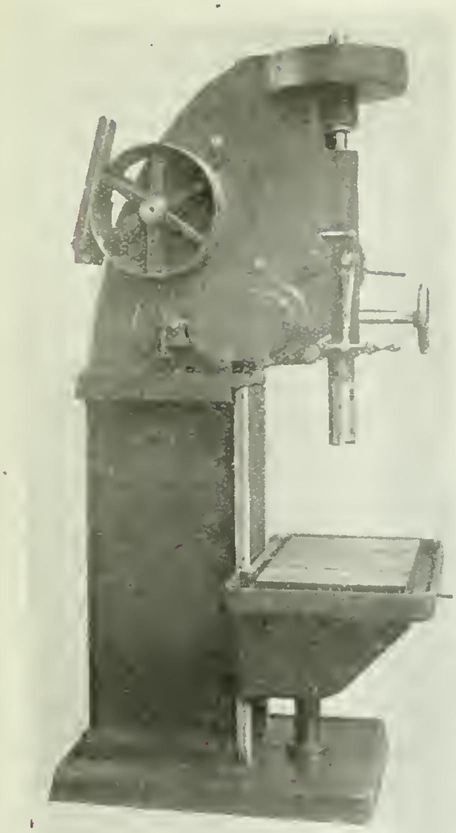
Change gears are employed to vary the spindle speed from 76 revs. per min. to 614 revs. per min. while by changing the top driving gears, speeds one half and one third of these are obtained.

Feeds also are varied through change gears, a reaming feed 3 1-3 times the drilling feed being provided. Six feeds are provided on the standard machine, reaming from .020 to 0.89 in. and drilling .005 to .024 in. per revolution of spindle. Considerable attention has been given to the locating of the operating levers, in order to make them suit the logical movements of the operator. Tight and loose pulleys are used for controlling purposes, and a spring device holds the belt shipper securely in either position. When in the off position, a brake is applied to the spindle to secure prompt and effective stoppage. The change from drilling to reaming speeds is made by push rod at left of spindle.

These machines are well suited for gang arrangement, a four spindle unit being illustrated herewith, either continuous or independent tables being furnished as required. Elevating screws are provided for the tables which are constructed so that they can readily be bushed for boring bar. From center of spindle to face of column is 10 in.; from end of spindle to plain table 32 in.; length of feed, 12 in.; vertical adjustment of table, 18 in. The single machine requires 29 in. x 46 in. floor space



GANG ARRANGEMENT, SINGLE PURPOSE HIGH SPEED DRILLING MACHINE.



SINGLE PURPOSE HIGH SPEED DRILLING MACHINE.

and weighs 2,550 lbs. A four spindle gang requires 101 in. x 46 in. floor-space and weighs 10,250 lbs.

The makers of this drilling machine are Baker Bros, Toledo, O.

PRESS FOR STAMPING WASHERS FROM SCRAP PLATES

SCRAP sheets and plates bring a small price when sold as scrap, but when punched into washers realize a much higher figure. The press shown in the illustration herewith is specially adapted for making washers and other stamped specialties from scrap plates and sheets or from new material, its most useful field being in the utilization of waste material by converting it into standard or special washers, large quantities of which are always used around railroad and industrial plants.

The frames are one solid casting of the open gap type, on which is mounted the gearing (a single reduction except in case of motor drive) plunger, cam shaft, dies, etc. The plunger has broad wearing surfaces and is equipped with a bronze taper gib to take up any wear. Fastened at the bottom is the die and piercer, the former for cutting the outside of the washer, and the latter for punching simultaneously the centre hole. The punch is on the bottom and is held in a substantial punch holder block on the lower jaw of the frame.

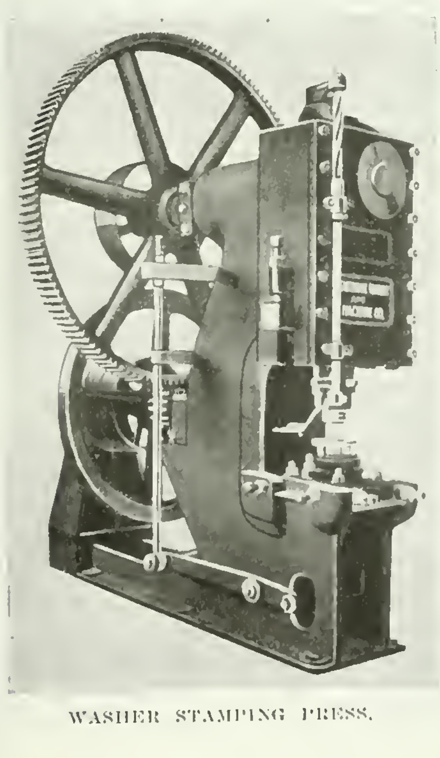
Surrounding this punch is the stripper ring, operated through connecting rods and lever from a cam on the back of the main shaft. In an annular space between the piercer and die are a series of knockout pins for knocking down the washer which sticks in the upper part of the die mechanism and goes up with the upward stroke of the plunger. These pins are operated by a bar passing crosswise through the ram and, at the top of the stroke, stopping against a pair of set screws in lugs cast on the frame.

At the left front side of the machine is a vertical shaft which is splined at the top with a steep pitch thread. This passes through a nut which is fast to the top of the plunger. The up-and-down stroke of the ram imparts a rotary motion to the shaft. On the bottom of the shaft is the hand or cup which receives the knocked out washer and throws it into a pile or suitable receptacle.

The back of the main shaft is equipped with a tight pulley as is also the fly wheel shaft. This pulley drives the machine on light work when operated the same as a fly-wheel non-geared press. In this case the fly-wheel, pinion and shaft are removed. Operating without gears makes the machine a rapidly acting press the speed being limited only by the skill of the operator handling the material.

The machine may be used for various forms of stamping, punching, shearing, etc. Where used for scrap reclaiming only, it may be placed at the scrap bins. Only one man is required to operate it, he using both hands to hold the material as the ram operates continuously. By a special die construction, the press makes a complete washer at each stroke of the ram, insuring the concentricity of hole with the outer circumference. It leaves the washer perfectly flat and with clean-cut edges. The punched washer is thrown out automatically into a box or to a pile by a mechanical hand operated from the slide.

The machine is equipped with a pulley for belt drive or, when specified, motor bracket and suitable gearing for electric motor drive and one set of punches and dies for any size within range of the capacity. Five sizes of this machine are built by the Southwark Foundry & Machine Co., Philadelphia, Pa.



WASHER STAMPING PRESS.

CANADA'S IRON OUTPUT

REFLECTED in Canada's largest production of iron and steel, are the output of the munitions industry and the larger domestic requirements of last year, together with exports of billets and wire. J. McLeish, B.A., chief of the Department of Mines, division of statistics and mineral resources, has compiled the following table. The summary of iron and steel statistics, 1914-1915, are as below:—

	1914. Short tons.	1915. Short tons.
Iron ore shipped	244,854	398,112
Canadian iron ore charged to blast furnaces	182,964	293,305
Imported iron ore charged to blast furnaces	1,324,326	1,314,957
Iron ore charged to steel furnaces	37,686	74,872
Pig iron made	783,164	913,775
Pig iron and ferro-alloys exported	19,063	26,545
Pig iron imported	78,680	47,842
Ferro-alloys made	7,524	10,794
Ferro-alloys imported	22,147	12,758
Pig Iron and ferro-alloy consumption	782,452	959,254
Pig Iron used in steel furnaces	619,030	747,834
Steel ingots and castings made	828,641	1,020,336
Steel rails made	428,225	232,411
Canadian coke used in iron blast furnaces	330,269	578,743
Imported coke used in iron blast furnaces	590,902	86,022
Iron and steel imported	878,179	771,007

THE BET

CHILDREN are never quite so ignorant as we think they are. There is a London man who said to his little daughter one evening:

"Now that the stork has brought you a dear little baby brother, I want you to sit down and write a nice letter about it to Brother Jack at boarding school. Tell him we went out and looked under one of the big cabbage plants, and there we found a dear, sweet baby brother, with blue eyes and red hair, that the kind stork left for us."

"Yes, papa," said the little girl, meekly.

She wrote her letter, and when her father went to post it, he thought, since it was not yet sealed, that he'd see what she had said.

What she said was this:

"Dear Jack, I win the money. It's a boy."

A Moving Appeal.—"Yes," said the naive young person, "we invited three soldiers for dinner on Christmas Day. We felt we just had to, for mother said it was a crime to eat turkey at 42 cents a pound unless we had some sort of excuse for it. So we hunted one up quickly, and we never had such a delightful Christmas as we did entertaining three perfect strangers. What about them? Well, they stayed until nearly twelve o'clock, and I think they'd be here yet, smoking cigarettes, if one of them hadn't happened to be Scotch, and we suggested that they would have to be taking night cars very soon!"

Vol. XVII. JANUARY 11, 1917 No. 2

THE PAPER SITUATION.

IN view of the continued seriousness of the paper situation in Canada, and of its perhaps no less acuteness in the United States, it may not be without interest if we refer to some observations made by our contemporary the Pulp and Paper Magazine relative to the scarcity and high cost of newsprint and other publication stock. In a recent issue, a two-fold protest is lodged. On the one hand, protest is made against the danger and injury which will come to the whole pulp and paper industry if the chief interest in the manufacture of paper is to be centered in the stock market; on the other, exception is taken to inclusion of paper stocks in the "war baby" class.

"Canada," to quote some of the data given, "owns 40 per cent. of the world's supply of pulpwood, but at the present time only produces 5 per cent. of the world's paper. The United States, on the other hand, owns but 18 per cent. of the world's pulpwood supply, yet produces 42 per cent. of the world's paper production. When Canada comes into her own as a paper-making centre and produces 40 per cent. of the world's supply instead of 5 per cent. as at present, people who now scoff at the paper industry will have a chance to revise their opinions. Again, even if peace were to come tomorrow, the present prices prevailing for paper will be maintained for a year or two at least."

In recent months—we "make no bones about it," our readers have been called upon to pay a higher subscription rate for this journal, added to which the paper quality is less substantial and the space devoted to their interests, compressed by using closer faced and in some departments, smaller type. The figures quoted above will we trust serve to explain effectively the conditions which face Canadian publishers, no matter the nature of their medium, and show at same time that the return to normal is quite far removed. A. G. McIntyre, Paper Expert of the Newspaper Publishers Association, estimates that, if the normal paper consumpt—6 to 10 per cent. per year in the United States is maintained, and taking as a basis the meantime production of Canadian and American mills, we on this continent will have to face a shortage during 1918 of some 1,500 tons per day. Continuing he states that, "when the price of newsprint dropped to a minimum of 2 cents delivered, a profit of $10 to $15 per ton had always been maintained by Canadian mills." Under 1917 contract prices, profits from $30 per ton upwards are being made." The advantage of the Canadian producer over the American producer, he considers to be considerably in excess of $5 a ton, and he believes, in view of the current relation of supply to demand, "that the opportunity for Canadian pulp and paper mill development, even under present extreme conditions, is both safe and highly remunerative."

Industrial enterprise, we may say at once, is indissolubly linked with the stock market. In more immediately pre-war days, pulp and paper industries were however rather too lean of appearance to whet the public appetite. Paper-making was then an enterprise engaged in for the benefit of those directly concerned; now, with profits of thirty dollars per ton and upwards, the benefits will accrue for the most part to those with but slight or entire lack of knowledge of even the different plant locations and who care not a "hoot" if they ever know under the circumstances.

The "high cost of living" to which we are all more or less subject has a good excuse in the war, at least so we are made to believe. Our stock and other market manipulators have however more to do with the H.C.L. than has the war, in the final analysis. We are anticipating larger benefits to accrue to us industrially in peace time, both in the matter of meeting our own requirements and those of nations of whose existence we have hitherto had but a hazy geographical knowledge. It is not assuming overmuch when we express the opinion that little in either direction is likely to be realized, unless more attention be given our industries for their value as such, and less as financial footballs.

MORE EFFORT, MORE MEN, MORE MONEY.

IF there is one thing more than another that the recent peace scare has demonstrated, it is the fact of our being in this war to the "knock out" stage. Beyond the confines of the stock market, where expediency, imagination, or reality, stand ever ready either to woo or create opportunity, little excitement and probably still less business dislocation resulted from the now silenced dual-source peace proposals with their "soft pedal" heralding. Renewed and still more forceful expression has been given of the determination of Britain and her Allies to prosecute the war to its logical conclusion, and in this respect the very untimeliness of the peace suggestions have not been without a salutary effect. As we see it, the Dove of Peace—were that the fair bird or another in its borrowed plumes—has tucked its head under its wing for many months to come, under which circumstances, munitions, men, and money, to the limit of our capacity and resources must needs be our New Year programme. Our Imperial Munitions Board, our National Service Commission, and our Patriotic Fund Executive, all war-created organizations, are more intensely than ever war-in-earnest. Coupled with the "Thrift Campaign" now been planned by our Minister of Finance, Sir Thomas White, it is abundantly evident that our efforts and responsibilities are primarily those of war concern, and, therefore, wasted if otherwise directed and evaded. Much is expected of us during the coming year and largely dependent on our measure of response—ourselves and our substance, will the ushering in of a peace worth-while be hastened.

INDUSTRIAL NOTABILITIES

MEURIG LLOYD DAVIES, vice-president, Standard Chemical, Iron, and Lumber Co., of Canada, manufacturers of wood distillation products, Royal Bank Building, Toronto; representative of the United Alkali Co., of Liverpool, England; director, Port Hope Sanitary Manufacturing Co., of Toronto; director, Standard Iron Co., of Montreal; director, North American Chemical Co., Bay City, Mich.; director, Robert Gage Coal Co., Bay City, Mich., was born at Liverpool, England, October 3, 1865, son of William Hamlet Davies and Elizabeth Lloyd (Griffith) Davies, of that city.

MEURIG LLOYD DAVIES.

He was educated at Liverpool College, following which in 1882 he was articled to James Muspratt & Sons, of Liverpool, chemical manufacturers, becoming manager of the works there in 1889. The above firm was absorbed by the United Alkali Co. about a year later. In 1892 he was made manager of the Hutchison Works of the United Alkali Co., at Widnes, Lancashire. From 1899 until 1913 he was resident in the United States, and filled the position of general manager to the North American Chemical Co., Bay City, Mich. In 1913 he came to Toronto as general manager of the Standard Chemical, Iron, and Lumber Co., being made vice-president in the same year.

Mr. Davies married Sarah Elizabeth Sinister, daughter of Timothy Sinister, Runcorn, England, August 23, 1893, the family consisting of two daughters. His clubs are: Toronto, Albany, Rosedale Golf and R.C.Y.C.; his societies: A.F. & A.M. (32° Scottish Rite); Society of Chemical Industry (Canadian Section); St. George's Society. In politics, he is Conservative, and in religious creed, Anglican. His residence is 31 South Drive, Toronto, Ont.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., Jan. 8, 1917. With the turn of the year, commercial and industrial interests have resumed their pre-holiday activity. The business outlook for the ensuing twelve months equals, if not surpasses, that of the like period just closed. More or less relief has been recently afforded transportation difficulties by reason of additional rolling stock having been made available.

Pig Iron

The production of pig iron is being affected by the marked scarcity of coke, together with the trouble experienced in delivery of the raw materials to the furnaces. The coke situation has recently been of such a serious nature as to cause the temporary or partial shut down of several blast furnaces. No price advances have taken place during the week, but the high level reached a couple of weeks ago is being maintained. It is generally conceded, however, that the crest of the advance has been reached.

Steel

The steel situation has failed to resume its pre-holiday activity, the present market being exceptionally quiet. In addition to the adjustments that are habitual at this period of the year, the quiet tone noticeable is no doubt due to the uncertainty still prevailing in some quarters as to the ultimate outcome of international peace negotiations. Production continues unabated with prices at the high level. Blue annealed sheets have been advanced $10 per ton, the Pittsburg quotation being $4.50 per hundred. Black sheets are lower, the base being $5 per hundred. Local prices on sheets show a tendency to advance. Dealers here have recently revised their quotations on boiler plates and tubes; plates are now $5.40; heads, $5.75 and tank plates (3-16 in. thick) are $5.50. Changes in tube prices effect the 3 and 4 inch seamless sizes, the demand for these being very heavy. The former are now $55, and the latter $75 per 100 feet.

High Speed Steel

The situation in high speed steel shows little change. The demand continues heavy and prices are very firm, ranging from $2.50 to $3 per pound.

Metals

The market appears still affected by peace talk. Copper shows a weaker tendency. Tin is slightly stronger and temporarily higher. Spelter is firm and steady. Lead continues very firm, with slight scarcity apparent.

Copper.—The market is still influenced by the uncertainty that still prevails regarding the present political situation. Activity in resale metal has apparently weakened the market, but producers conitnue to quote high prices. The market has declined both in London and New York; the latter now quoting 29 cents for lake and 28¼ cents for electrolytic. The situation here is quiet, but dealers are firm in their quotations; lake and electrolytic being 36 cents, and castings 35 cents per pound.

Tin.—Strength was given the market following a little increased activity during the latter part of the week. The general situation, however, is without material change. Advances are noted in both London and New York reports; New York being 1¾ cents higher than a week ago. Dealers here are quoting 47 cents on a steady market, this being an advance of one cent per pound.

Spelter.—Satisfactory conditions prevail in the spelter market, producers are holding firm on prices. The abnormal production which appeared evident some months ago has not materialized, as the additional facilities have been offset by the closing of a number of mines. The local situation continues steady with prices firm at 13½ cents per pound.

Lead.—The market in lead continues very firm in face of recent and current disturbances. This is partly due to an apparent scarcity of available metal. New York is still quoting 7½ cents for "trust" metal, with "independents" asking ⅛ cent higher. Prices here are unchanged at 10 cents per pound.

Antimony. The market is holding firm, prices being well maintained. Dealers here are quoting 15 cents per pound on a quiet market.

Aluminum.—The market is very steady, the quotation here having returned to 70 cents per pound.

Machine Tools and Supplies

With the passing of the holiday season the machine tool trade is again resuming some of its previous activity. The recent placing of large munition contracts is beginning to reflect itself in the demand for additional equipment. The abnormal high cost of raw materials and labor has resulted in higher prices for all lines of tools. The expense entailed in equipping a plant at the present time is from 50 to 75 per cent. greater than that of a couple of years ago.

Scrap

Following a quiet week in the scrap market the general tone is easier, more especially in old copper. Much of the inactivity is owing to the difficulty of securing shipping facilities, although the demand has also fallen off. The local changes this week are a decline of 2 cents on old copper, the current quotations ranging from 19 cents for light, to 23 cents for heavy and old wire. Owing to the curtailment in pig iron production the demand on machine cast iron has increased, an advance of 5 cents per hundred, placing this class of scrap on a $20 per ton basis. Old shafting is much in demand, the price quoted being 20 cents, an advance of 3¼ cents. Stove plate is higher, the local uotation of 13 cents being one cent over that of last week.

Toronto, Ont., Jan. 9.—The freight situation is perhaps the outstanding feature in industrial circles this week. Conditions have been steadily getting worse for some months, until now a crisis has been reached. This is particularly so as regards coal, due largely to the shortage of motive power and cars, and also congestion in the freight yards. It is proposed to take off a number of passenger trains between Toronto and the U. S. border, so as to release engines for hauling freight trains.

Steel

The peace proposals have had less effect on the steel market than was anticipated, prices still advancing. How long this upward movement will continue is difficult to say, but in any case some products will be affected more than others. Take, for instance, ship plates and steel rails, for which there will be as big a demand after the war as there is at the present time; prices on these, particularly the former, will yet reach a considerably higher level, and the relative advance in plates will be greater than in bars and shapes. Plates have advanced 40c per 100 lbs. since the beginning of the year, ¼-in. and larger being now quoted at $5.40; heads, $5.70; and tank plates, $5.50 per 100 lbs. Local warehouse price on steel bars is now 3.75c, and, on small shapes, 4c per lb. Wrought iron pipe, black and galvanized, has advanced 2 points, while higher prices on black sheets have been announced. This advance in sheets has been expected, as the situation in the primary market is tight, due to shortage of sheet bars and scarcity of fuel and labor. Deliveries are getting very backward on account of conditions at the mills, and indications point to further advances. Galvanized sheets are unchanged in the meantime, the weakness in spelter having some effect on the market. Local steel merchants report a good volume of business during December, and believe that January will be even better. Deliveries from mills continue slow, with no sign of improvement. Local shipbuilders are asking for considerable tonnages of steel plates, but are experiencing much difficulty in getting this material, even at the fancy prices now ruling. The scarcity of ship plates is restricting development in the shipbuilding industry.

While the steel market in the U. S. is less active than it was before the peace proposals were made, there is little sign of weakness. As a matter of fact, prices are being well maintained, which emphasizes the strong technical position of the market. Foreign demand continues, despite the existence of peace talk and uncertainty in the international situation. Chicago warehouse prices are higher, bars being quoted at 3.75c; bars, 2 in. and up, 4.25c; structural shapes, 3.85c; and plates, 4.50c per lb. Bessemer and open-hearth billets are now being quoted at $60 per ton, Pittsburgh.

Pig Iron

There is no change in the pig iron situation, the general tone of the market being strong, though quiet. Prices of domestic pig irons are still withdrawn. In the U. S., the pig iron market is quiet. Buyers continue to wait for developments in international affairs before proceeding with the covering of requirements over the second half of the year. Prices continue firm, but unchanged.

Coal and Coke

The situation in coal and coke is getting more acute, and there appears to be little possibility of any pronounced relief until the spring. Shortage of motive power and congestion of freight in the railway yards are the principal causes, but efforts are being made to relieve the situation. Coal dealers warn consumers not to buy more coal than they really require, otherwise the shortage will become more serious. Prices are higher, steam coal is selling at $8.50, and best slack at $9 f.o.b. cars. Prices on coke are unobtainable.

Scrap

The scrap market is very unsettled, due to peace talk and freight congestion on the railways. Prices on all grades of copper and brass scrap have declined approximately 2c per pound, but steel scrap has not been affected. The embargo which was placed on the export of steel turnings has been extended to include all grades of steel scrap; this is having a tendency to weaken the market on same. The demand for scrap generally is good, notwithstanding the unsettled situation.

Machine Tools

The market continues quiet, with no developments of particular interest to note. The prospect of further large orders for munitions being placed in Canada instead of in the U. S. has improved the outlook, and a large volume of business is expected. Another credit of $50,000,000 has been arranged by the Canadian banks for the British Government to finance further contracts for munitions.

Supplies

Prices on machine shop supplies are still advancing. New and higher prices on lubricating and machine oils have been announced. These oils will in the future be sold on a bulk basis, while an extra charge of $2 will be made for the barrels. The prices given in the selected market quotations have been revised accordingly. Castor oil is higher, and is now quoted at 25c. Lard oil has also advanced and is now $1.45. Acme cutting oil, Union thread cutting oil, and fuel oil prices have also been revised upwards. New discounts have been issued on brass machine screws, but iron screws are unchanged. Packings have been advanced 2c. per pound.

Metals

The metal markets are still being influenced by peace talk and the situation is consequently somewhat unsettled. Copper has declined, otherwise prices are unchanged locally. Business which was quiet over the holidays is improving, and a renewal of former activity is anticipated.

Copper.—Although copper has declined on account of peace talk, the position of this metal is still very strong, and a recovery is more than likely. The consumption of copper will be very heavy even after the war, which will have a tendency to keep prices up. Locally copper has declined 2c. and quotations are entirely nominal at 36c per pound.

Tin.—The market is steadier with a fair volume of business. Quotations are unchanged and nominal at 48c. per pound.

Spelter.—The situation is unchanged and the market has a quiet tone. Local quotations steady at 13½c. per pound.

Lead.—The market is characterized by a general tone of dullness. The leading interest maintains its price at 7.50c. New York, but the outside interests are understood to be selling below that figure. Local price 9½c. per pound.

Antimony.—The market generally is featureless, with quotations unchanged at 18c. per pound.

Aluminum.—Quotations are firm but nominal at 68c. per pound.

Solders.—There has been a decline in prices of solders. Guaranteed is now quoted at 28½c., and strictly at 25½c. per pound.

BIG CONTRACT ABANDONED

THE seven million dollar contract for the improvement of the port of St. John (Courtenay Bay side) has been thrown up by the contractors, the Norton, Griffiths Co., and all work discontinued.

The St. John harbor works were part of the general scheme of the present Government for the improvement of

Canadian ocean ports. A good deal of work has been done, but the contractors, who were to have completed the larger part of the improvements by next spring have not made the necessary progress and are now apparently unable to go on. In addition to the actual harbor work, the plans included the construction of a large drydock on a subsidy basis.

It is regarded as unlikely that the Public Works Department will take over the uncompleted work. If the completion is not to be deferred until after the war, the contract will probably be transferred. Something like $3,000,000 has already been expended on undertaking.

MANUFACTURING PATRIOTISM

SOME time ago the Imperial Munitions Board at Ottawa found themselves facing a 75 per cent. increase in the already high prices of acetone supplied from the United States. They decided upon its manufacture in Canada. After full investigation, it was reported to the board that the distillery at Toronto, of Messrs. Gooderham & Worts, was the most suitable of all the Canadian distilleries for the purpose. The Munitions Board thereupon offered to lease the building and plant from the company for the duration of the war; the rental to be based on the average net profits of Messrs. Gooderham & Worts, for the past three years, plus interest on their actual investment. The company within a few days thereafter refused the offer of the Munitions Board. In effect, the whisky distillers said:

"This company will lease its distillery, its buildings and its complete plant to the Board only upon the understanding that it shall receive no compensation whatever from the Imperial Munitions Board. Furthermore, we are authorized to say that if the services of our general manager, Col. H. E. Gooderham, and his son, Capt. Gooderham, are of any use to the Board in the operation of the company's plant thereafter, they are offered on like terms."

Needless to say, the offer was promptly and gratefully accepted as a result, and the Board is now operating the Gooderham & Worts plant, with Col. Gooderham as general manager, and Captain Gooderham as assistant general manager, paying nothing for either plant or managers. The Imperial Government has asked the Munitions Board to convey to Messrs. Gooderham & Worts its thanks for their munificent and patriotic action.

Trail, B.C.—The Consolidated Mining & Smelting Co., is preparing plans for enlarged operations in the refining of copper with a 50 per cent. increase to its present facilities. With such increase effected, the refinery will have capacity for producing about 11,000,000 pounds of refined copper per annum. There is no other copper refinery in Canada at the present time. The Consolidated Mining Co., was a pioneer in the treatment of zinc electrolytically, and, from the resultant production a new source of income was developed the past year.

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles. British Consul General.

INDIA—Calcutta. Director General of Commercial Intelligence.

ITALY—Genoa. British Consul General. Milan. British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa. British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—H. R. Poussette, Reconquista, No. 46, Buenos Airés. Cable address, Canadian.

AUSTRALIA—D. H Ross, Stock Exchange Building, Melbourne. Cable address. Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Canecoma.

CUBA—Acting Trade Commissioner, Lonja del Commercio, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—G. B. Johnson, P. O. Box 109, Yokohoma. Cable address. Canadian.

HOLLAND—Acting Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrivskaya, Ploshch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 27-28 Pearl Building, East Paradise, Leeds. Cable address, Canadian. F. A. C. Bickerike, Canada Chambers, 36 Spring Gardens, Manchester. Cable address, Cantracom. J. T. Lithgow, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.

SPECIAL TRADE COMMISSIONER—LUMBER

H. R. McMillan, visiting Europe, Africa, Australasia and the Orient.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin, Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum Grubbeged No. 4, Christiania, Norway. Cable address, Sontums.

CANADIAN HIGH COMMISSIONER'S OFFICE

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

St. Catharines, Ont. — The Kinleith Paper Co. will build an extension to their mill here.

Toronto, Ont.—It is reported that a large steel plant may be established here under the Imperial Munitions Board.

Thorold, Ont.—The Exolon Co., manufacturer of abrasive wheels, has awarded the contract for an addition to its plant. Estimated cost, $100,000.

Timmins, Ont.—The Murray Mogridge Mining Co., proposes to build a compressor plant and stamp mill on property near here. Engineer, C. E. Jury, Toronto.

Brandon, Man.—Fire recently destroyed the Brandon Machine & Implement Works, the damage being estimated at $20,000, which is partly covered by insurance.

Toronto, Ont.—City Architect Pearse has issued a permit for a 20,000-gallon water tank to Adams Bros., on King Street, near Niagara. The tank will cost $1,240.

Vancouver, B.C.—Fire which started on Jan. 5 in Wood, Vallance & Leggatt's paint warehouse, caused a loss of over half a million dollars, fully covered by insurance.

Preston, Ont.—Fire here on Jan. 7 destroyed the blacksmith and finishing shops of the Preston Car and Coach Co. The origin of the fire is not known. The loss is estimated at about $100,000.

Galt, Ont.—Damage to the extent of $35,000 was done by fire on Jan. 3 to the factory of the Crown Hat Co. All machinery in the stitching-room was destroyed. The loss is fairly well covered by insurance.

Port Arthur, Ont.—The Port Arthur Copper Co., which was recently incorporated at Toronto, propose to build a concentrating plant in this district. F. M. Connell, mining engineer, Toronto, is interested in the concern.

ELECTRICAL

Weston, Ont.—At the elections on Jan. 1, the hydro by-law was carried by a large majority.

MUNICIPAL

St. Marys, Ont.—The Town Council contemplate installing a sewage disposal plant.

Midland, Ont. — The Hydro-electric by-law carried here by a majority of 55 on Jan. 1.

Strathroy, Ont.—The ratepayers on Jan. 1 carried a by-law endorsing the hydro plebiscite.

London, Ont.—It is proposed to utilize 22 acres of city property on Egerton Street for factory sites.

Cochrane, Ont.—A by-law for a $40,000 loan was carried at the recent elections, also a by-law re rate of taxes.

Oil Springs, Ont.—Ratepayers on Jan. 1, strongly endorsed the by-law enabling the Council to spend $10,000 on installing hydro.

Port Dover, Ont.—The ratepayers on Jan. 1, granted fixed assessment to the Ivey Greenhouse Co., figures on the vote being: For, 156; against, 31.

Highgate, Ont.—The ratepayers on Jan. 1, carried by a majority of 69 the enabling by-law authorizing the installation of hydro. The figures were: For, 75; against, 6.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

Markham, Ont.—By a vote of 96 to 8 the ratepayers on Jan. 1, endorsed the proposition to expend the sum of $6,000 on the extension of the present waterworks system.

New Toronto, Ont.—The by-law has been carried fixing the assessment at $4,000 per acre on property, etc., of Brown's Copper & Brass Rolling Mills, Ltd. The company is making important extensions to the plant.

Listowel, Ont.—A by-law to expend $20,000 on public and high school improvements, was carried by the narrow margin of 41. A second by-law, providing for an expenditure of $18,000 on street paving, was defeated by 187 majority.

Sarnia, Ont.—The flow of water from the new basins placed in operation at the new waterworks at Point Edward has shown an output of half-million gallons in 24 hours. This is not as large a flow as was looked for as these basins are right on the bank of the river. It is expected that the city will put down more basins, as the plan is declared to be a good one, and all that is needed is enough basins to give the required amount of water.

CONTRACTS

Vancouver, B.C.—A large piling contract has been awarded by the C. P. R. to the Vancouver Creosoting Co., which only recently began operating its new big plant in North Vancouver. The contract amounts to $150,000, and the piles will be used in the extension to Pier D, which the C. P. R. is now undertaking. A large number of the piles will be 130 feet in length.

Montreal, Que.—The Montreal & Southern Counties Railway Co. has placed an order with the Ottawa Car Co. for six new electric interurban passenger cars, consisting of three motors and three trailer cars. The new cars will be fifty-five feet long, with a seating capacity of sixty-two passengers. They will be equipped with four 50-horse power motors, improved Peter Smith heating and ventilation systems, smoking compartment.

MARINE

St. John, N.B.—The Eastern Steamship Corporation fleet of steamers, docks and warehouses, etc., have been purchased by Hayden, Stone & Co., of Boston, on behalf of a syndicate, who will reorganize the corporation. The price paid was $3,366,000, which includes a large interest in the Boston and Yarmouth Steamship Co.

1916 Lakes Season.—The lake marine season of 1916 will be known as the longest on record, boats encountering ice at the start and finish. Thirteen vessels passed out of existence during the nine months of navigation, but most of them were small and only two were lost in collisions. Two boats stranded and were total losses; three were destroyed by fire, and six foundered. Four of the lost vessels went down in the gale which swept Lake Erie on Oct. 20, and the steamer "Merida," which went down with all hands, was the biggest monetary loss. She was insured for $200,000. The loss on the S. R. Kirby, which went down in Lake Superior early in the summer, was the next greatest loss. She cost the underwriters $120,000. Total loss of life was 70, as against 15 the year previous.

BUILDINGS

Toronto, Ont.—A new office building and warehouse will be erected at 69 Adelaide Street West, by S. Frank Wilson & Sons, publishers. Plans for the building are not yet complete, but, according to present intentions, it will be either of brick and steel, or concrete and steel construction, 68 by 200, and probably nine storeys high.

TRADE GOSSIP

St. Catherines, Ont.—The St. Catherines Brass Works are building a foundry.

Guelph, Ont. — The International Malleable Iron Co., propose building an extension to their foundry.

Britain Requisitions Copper.—Supplies of unwrought copper have been requisitioned by the British Government.

Victoria, B.C.—The Aetna Iron & Steel Co., is applying for a site on the terminal area on which to erect a plant.

Sudbury, Ont.—The Murray Mining Co., are negotiating for hydro power for the development of a mining property three miles from here.

New Munitions Credit.—Another credit of $50,000,000 by Canadian banks to the Imperial authorities for munitions is announced. This makes a total of $250,000,000 provided in Canada.

Cobourg, Ont.—The Federal Steel & Foundry Co., are having plans prepared for a steel plant and rolling mill to cost about $250,000. T. H. Cole of the Corbett Foundry & Machine Co., Owen Sound, Ont., is manager.

Armstrong, Whitworth Co. of Canada, Ltd., Montreal, who are represented in Winnipeg by Kelly Powell, Ltd., are considering opening up a Vancouver branch with the view of developing their business in mining drills, steel, etc., throughout the mining districts of British Columbia.

Winnipeg, Man.—Application will be made at the next session of the Legislative Assembly of the Province of Manitoba for an Act to incorporate the Transcona Electric Railway Co., with power to build, operate and equip electric railways, and to do an electric light, power and gas business.

H. W. Petrie, of Montreal, Ltd., Montreal, are opening a large department for the sale of wholesale and retail automobile supplies and accessories, in addition to their regular line of iron and wood working machinery. A. Carriere, formerly with John Millen & Sons, Ltd., Montreal, is in charge of this department.

Armstrong, Whitworth of Canada, Ltd., has just opened new, larger, and up-to-date offices in Montreal at Nos 298-300 St. James Street. The new premises consist of three floors and basement. It is the intention to carry a very complete stock of their product, in order to ensure quick delivery, particularly of small orders.

Samuel Osborn, Canada, Ltd., will shortly establish a plant in Montreal for the purpose of manufacturing high-speed tools for machine shops and special uses. They will also have a hardening plant in charge of a Sheffield expert for treatment of steels. This arrangement will enable the company to make quicker delivery and give better service generally to their customers.

Montreal, Que.—The machinery and equipment for the new tire plant which the Armstrong Whitworth Co., are building is arriving, and they hope to have the two new six ton Heroult furnaces in operation in from 60 to 90 days.

Toronto, Ont.—Forgings, Ltd., 27 Atlantic Avenue, has taken out a building permit to instal three fuel oil tanks at a cost of $2,000.

Canadian Pneumatic Tool Co.—At a meeting of the directors of the Canadian Pneumatic Tool Co., held recently in New York, George J. Sheppard, who has been connected with the concern as manager for a number of years, was elected vice-president. This honor was conferred on him in appreciation of his efforts in making the Canadian subsidiary a success. He retains his position as Canadian manager, W. O. Duntley being the president, and W. B. Seelig, secretary-treasurer. It is the intention of the directors to erect an up-to-date factory in Canada, with a view to coping with future trade conditions.

Lack of Ocean Tonnage.—Lack of ocean tonnage may prevent the shipment of the fifteen hundred miles of steel rails which the Canadian Government undertook to supply for use in France. Canada is providing the rails, and, if the British Government can get them across the ocean, the arrangement entered into two weeks ago will be carried out. The tonnage now available, however, is insufficient, and if no more is forthcoming the rails can hardly be transported with the expedition that is necessary. Three hundred miles of steel from the Government railways are going across at once. If the rest cannot be taken over in time it is assumed that steel mills in Great Britain will be used to turn out what is required.

To Use Canadian Woods.—Canadian lumber merchants will be glad to learn the decision of the British War Office to make larger use of Canadian woods in the future manufacture of articles required for war purposes. This agreement is the outcome of representations made by Sir George Perley, who put the lumbermen's case strongly before the authorities, more especially as regards red and white pine. Specimen, prices and samples of pine were submitted to the War Office, with the result that an inspector of equipment and supplies has furnished for the merchants' guidance lists of 68 articles in which the use of Canadian woods will be provided for in the specifications governing their manufacture.

TENDERS

Winnipeg, Man.—Tenders will be called until February 12, 1917, for works required for the completion of the new Parliament Buildings, which include the following: Heating and ventilating, electric conduit and wiring. Thos. H. Johnson, Minister of Public Works, Winnipeg.

St. Lambert, Que.—Tenders will be received up to January 22, for the supply of a horizontal shaft centrifugal pump, electric motor and switchboard. Specifications may be obtained from H. A. Gibeau, Town Engineer, Town Hall, St. Lambert, Chambly Co., P.Q.

Toronto, Ont.—Tenders will be received, addressed to the chairman, Board of Control, City Hall, Toronto, up to January 16, for the installation of a 40 million Imperial gallon centrifugal sewage pump at the main sewage pumping station, Toronto. Specifications and forms of tender may be obtained at the Works Department, Room 6, City Hall.

Ottawa, Ont.—Tenders will be received up to January 15, for the construction of a reinforced concrete lighthouse tower and fog alarm building combined, and a wooden dwelling at Point Abino, Township of Bertie, Welland County, in the Province of Ontario. Plans, specifications, form of contract and schedule of wages, can be seen, and forms of tender procured, at the Harbor Master's office, Toronto, and at the post offices, Welland, Port Colborne, St. Catharines, Bridgeburg, Hamilton and Brantford.

INCORPORATIONS

The Kerr & Goodwin Machine Co., of Brantford, Ont., have increased their capital stock to $100,000.

The Duncan Electric Co. has been incorporated at Ottawa with a capital of $150,000 to manufacture and deal in electrical apparatus and supplies of all kinds at Montreal. Incorporators are J. H. Meagher, Henry W. Chauvin and James E. Coulin, all of Montreal.

The North Bay Toy Co. has been incorporated at Toronto, with a capital of $100,000, to manufacture toys, wooden, tin and metal wares of all kinds at North Bay, Ont. The provisional directors are: Leonard W. Henderson, George Gordon and Howard H. Thompson, all of North Bay.

The Acme Oil & Gas Co. has been incorporated at Toronto with a capital of $1,000,000 to acquire and develop mineral lands and deposits with head office at Sarnia, Ont. Provisional directors are William J. Barber, Clarence P. Smith and Frederick R. Reeves, all of Sarnia, Ont.

Port Arthur Shipbuilding Co. has been incorporated at Toronto, with a capital of $2,500,000, to take over the business of the Western Dry Dock and Shipbuilding Co., of Port Arthur, Ont. The provisional directors are: Donald R. Hossack, John G. Leckie, and Lorne L. Lillico, all of Toronto.

British Forgings, Ltd., has been incorporated at Ottawa with a capital of $50,000 to cast, smelt, forge and roll iron and steel, also to operate blast furnaces, forges and converters. Head office is at Montreal and the incorporators are F. G. Bush, G. R. Dennan and A. G. Yeoman, all of Montreal.

The Jarvis Optical Co. has been incorported at Toronto with a capital of $40,000 to acquire the business of Charles A. Jarvis, of Brantford, Ont., manufacturer of optical supplies and instruments. Provisional directors are Charles A. Jarvis, Norman J. Penwarden, and W. S. Brewster, all of Brantford, Ont.

PERSONAL

William Sherman Smith, harbor master of Dalhousie, N.B., for over twenty years, died on January 4, aged 65.

Bertram Dawson, president of the Dickson Bridge Works Co., Cambellford, Ont., died on Dec. 31, aged 36 years.

Capt. H. N. McMaster has been appointed Marine Superintendent of the Montreal Transportation Co., at Kingston, Ont. He has been assistant superintendent since 1913.

John Grundy, engineer at the works of the Canada Carriage Co., Brockville, Ont., was accidently killed on Jan. 1, in the performance of his duties. Deceased was 65 years of age.

Robt. Patterson, for forty-one years an employee of the G. T. R. and for the last seventeen years master mechanic in the repair shops at Stratford, Ont., has been placed in charge of the General Car & Machinery Co. plant at Montmagny, Que. His appointment was made by the Imperial Munitions Board, Ottawa, and the Grand Trunk is releasing him for the period of the war. Charles Kelso will act as master mechanic at Stratford in the interval.

Hugh McCulloch, one of Galt's most prominent residents, died there on January 8, in his sixty-first year. He was president of the Goldie & McCulloch Co., vice-president of the Galt Malleable Iron Co., and of the Galt Art Metal Co., and a director of the Gore Mutual Fire Insurance Co. A native of Galt, he was closely identified with the industrial progress of the city, but never held municipal office. He was educated at Whitby Grammar School and Upper Canada College.

INCORPORATIONS

The Empire Brush Co. has been incorporated at Toronto, with a capital of $40,000, to manufacture brushes and brooms of all kinds at Toronto. Incorporators are: Samuel Scott, Abraham Shulman, and Wilfred H. Taylor, all of Toronto.

The MacFarlane Shoe Ltd., has been incorporated at Ottawa with a capital of $400,000 to manufacture boots and shoes of all kinds at Montreal. The incorporators are Walter S. Johnson, F. W. Fairman and William S. Wilson all of Montreal.

Daylyte Lamp Co. has been incorporated at Toronto, with a capital of $200,000, to manufacture lamps and electrical supplies of all kinds at Guelph. The provisional directors are: James E. Carter, John Davidson and John Kennedy, all of Guelph, Ont.

The Cluff Ammunition Co. has been incorporated at Ottawa, with a capital of $1,500,000, to manufacture explosives and munitions of all kinds. Head office at Toronto. The incorporators are: Arthur W. Holmested, Lorne F. Lambier and Norman R. Kay, all of Toronto.

The Provost Mfg. Co., has been incorporated at Ottawa with a capital of $50,000 to manufacture stump pullers, trucks, wagons etc., at Edmonton, Alta. The incorporators are Pierre Provost of Legal, Alta., also George H. Stoddart and John, C. Sherry of Edmonton.

Forgings, Ltd., has been incorporated at Ottawa, with a capital of $100,000, to manufacture forgings of all kinds, munitions, and explosives, etc., with head office at Toronto. The incorporators are: William H. Irving, Henry H. Davis and Edward H. Brower, all of Toronto.

The Spencer Heating Co., of Canada, Ltd., has been incorporated at Ottawa, with a capital of $500,000, to manufacture boilers, heaters and furnaces of all kinds, with head office at Toronto. The incorporators are: Tilman H. O'Neil, Albert T. Hawley, and Hugh Polson, all of Winnipeg.

South Bay Power Co. has been incorporated at Toronto, with a capital of $1,000,000, to operate power plants in the Sudbury and Temiskaming districts of Ontario, with head office at Toronto. Provisional directors are: A. Fasken, G. H. Sedgwick, and Duncan McArthur, all of Toronto.

Standard Stampings, Ltd., has been incorporated at Ottawa, with a capital of $45,000, to carry on the business of stampers, founders and metal workers, with head office at Toronto. The incorporators are: James F. Edgar, Norman R. Tyndall, of Toronto, and James E. Maybee, of Port Credit, Ont.

Atlas Metal & Alloys Co., of Canada Ltd., has been incorporated at Ottawa with a capital of $50,000 to carry on the business of metal workers, machinists and smelters with head office at, Montreal Incorporators are C. M. Holt, Alexander Chase-Casgrain and Errol M. MacDougal all of Montreal.

The Stave Mfg. Co. has been incorporated at Ottawa, with a capital of $50,000, to maintain and operate saw mills and planing mills, also to manufacture staves and woodenware of all kinds, with head office at Montreal. The incorporators are: Harold Wooland, Walter H. Thomson and Walter F. Lee, all of Montreal.

The Michipicoten Power & Paper Co., has been incorporated at Ottawa with a capital of $6,500,000 to manufacture pulp, paper and paper substitutes of all kinds with head office in Toronto. The incorporators are William A. J. Case, James B. Taylor and William M. Smith all of Toronto.

The St. Catharines Machinery Co. has been incorporated at Toronto, with a capital of $40,000, to manufacture machine tools and machinery of all kinds, at St. Catharines, Ont. The provisional directors are: George Wilson, E. W. Marks and Harry Shortt, all of St. Catharines, Ont.

The Lytle Engineering Co., has been incorporated at Ottawa with a capital of $50,000 to manufacture all kinds of engineers and mill supplies and to carry on the business of iron and brass founders, engineers and millwrights etc., with head office at Montreal. The incorporators are F. G. Bush, G. R. Drennan and H. W. Jackson all of Montreal.

CATALOGUES

The Cling-Surface Co., 1057 Niagara Street, Buffalo, N.Y., have issued a very unique calendar of special interest to engineers and will gladly send a copy of anyone who applies to them.

Trucks and Turntables.—The Whiting Foundry Equipment Co., Harvey, Ill., have issued a catalogue, No. 124, superseding No. 78. This catalogue illustrates and describes a varied line of steel trucks, charging cars, turntables, buckets, core oven cars, etc.

Electric Hoists.—Bulletin M-1, of the Shepard Electric Crane Co., Montour Falls, N.Y., gives particulars of floor-operated electric hoists up to one ton capacity. The bulletin also contains a figured diagram accompanied by a table giving the corresponding dimensions.

Collapsing Taps.—Bulletin No. 34, issued by the Modern Tool Co., Erie, Pa., describes and illustrates the "Modern" adjustable collapsing taps. The principal features and construction of this type of tap are dealt with fully. Copies of the bulletin may be had on request.

Scientific Lubrication of Cutting Tools is the title of a bulletin published by the Cincinnati Lubricant Pump Co., Cincinnati, Ohio. The opening pages of the bulletin cover the history of cutting tool lubrication, followed by another dealing with the use and application of lubricant or "coolant" as it is termed. In the latter part of the bulletin, the "Fulflo" lubricant pump is described and illustrated and its merits dealt with fully.

Mechanical Stoker.—Bulletin B-2 deals with the type "E" underfeed stoker made by the Combustion Engineering Corporation, New York. The bulletin contains a full description of this stoker, particular attention being given to the principal features embodied in its design and operation. The illustrations show sectional views of the stoker and illustrations under various types of boilers.

Crossley Oil Engines.—A bulletin dealing with the new Crossley oil engine for running on crude, residual and refined oils, has been issued by Crossley Bros., Ltd., Openshaw, Manchester, England. The bulletin contains full details covering the design of this engine and its attachments, while the advantages claimed for it are given in detail. Reference is made to the economical fuel consumption of the engine, and its adaptability for burning various qualities of crude and residual oils. Details of a test on a 95 b.h.p. engine are included. The bulletin is fully illustrated.

Ammonia Fittings and Supplies.—The Canadian Ice Machine Co., Toronto, are distributing a new high class catalogue, dealing with the "York" ammonia fittings and supplies. This catalogue, which supersedes all pervious issues, illustrates and describes standard types of fittings, etc., for which patterns are already made. A complete line of fittings and supplies is dealt with as used in refrigeration plants, the first part being devoted to fittings and the second covering various types of condensers, ammonia receivers, coolers, distillers, oil and steam separators, brine coolers, and filters, etc. An extensive line of valves and fittings are illustrated, accompanied by tables giving the principal dimensions for each size. The concluding pages contain views of numerous installations featuring various types of "York" refrigerating machines. The catalogue contains 132 pages, with exceptionally good half tones. Copies may be had on application by interested readers.

Star Grinding Wheels is the title of catalogue No. 9, issued by the Star Corundum Wheel Co., Detroit, Mich., which deals with an extensive line of grinding wheels for all purposes. The three processes by which these wheels are made are briefly described, followed by a table showing general uses of grinding wheels and the process of manufacture best adapted and usually employed. Other useful tables deal with grinding wheel speeds, weights of wheels, decimal equivalents, selection of grades, etc. The catalogue contains a number of suggestions for taking care of wheels, ordering and rules for calculating speeds. There are also a number of rules for calculating list prices for various shapes to be used in conjunction with the price lists. A large number of grinding wheels of various shapes for different makes of grinding machines are illustrated together with the principal dimensions and prices. A safety code for the use and care of abrasive wheels is distributed with the catalogue. This is a very useful catalogue and is gotten up in an attractive manner.

BOOK REVIEWS

Ford Methods and the Ford Shops. By Horace Lucien Arnold and Fay Leone Faurote. 440 pages. 7 x 10 inches. Published by the Engineering Magazine Co., New York. Price $5. This book which is one of the latest additions to the Works Management Library, is a re-print of a series of articles that appeared in the *Engineering Magazine*. It was written for the most part by H. L. Arnold, but completed by F. L. Faurote after Mr. Arnold's death. Both authors worked with the direct co-operation of Henry Ford himself, and of the Ford engineers.

Graphical Solutions of Electric Railway Problems.—In an effort to overcome the difficulties attendant upon the use of analytical methods in the solution of electric railway problems involving the characteristics of motive power, A. M Buck, of the Engineering Station, University of Illinois, has developed a series of graphical methods which supply an accurate and easy means of attack applicable to any possible combination of electric motor characteristics and any range of conditions which may be met in practice. Diagrams have been developed to set forth the relationship between motor current and speed, between current and tractive effort, between speed and tractive effort, between speed and time, etc. The results of Professor Buck's studies are set forth in Bulletin No. 90 of the Engineering Experiment Station. Copies may be obtained on request from W. F. M. Goss, Director, Urbana, Illinois.

Railroads Use Heavier Rails.—The C. P. R. is giving out large rail orders, including 30,000 tons of 80-pound rails and 30,000 tons of 100-pound rails for 1917 delivery. As the Canadian mills are working overtime and orders are greatly ahead, the company is making inquiries in the outside market. The heavier rails, which our railways are constantly laying down, is a reminder of the radical change which has taken place with respect to freight transportation in the course of the past decade. The question of mere existence causes the railways to consider the matter of a doubled capacity—longer and heavier trains, cars double the size, locomotives of double power and haulage capacity, heavier bridges to sustain added weights, and 100-pound rails to sustain the doubled weight of traffic. All that was accomplished at the outlay of many millions by the C. P. R. and Grand Trunk. It solved the question, not only of mere existence, but of dividends. But for this departure the mileage in the hands of the receivers on this continent would be double what it is to-day.

The Cleveland Twist Drill Co., Cleveland, O., are distributing an attractive calendar, the upper part of which is entitled "The Critical Moment." It consists of a photogravure in colors, and depicts the critical moment in the making of a twist drill.

FOR SALE

GAP LATHE, 28 x 42 x 16 FT. BED, FOR sale, cheap. Guarantee Motor Co., Hamilton, Canada. (4)

ENGINE FOR SALE—50 HORSE-POWER Corliss; no reasonable offer refused if taken at once. Box 387, Chatham, Ont. (2)

BROWN-BOGGS MARKING MACHINE FOR 4.5 shells. Has been used for short time only, and is in good condition. Box 248, Canadian Machinery. (24)

FOR SALE—1 ¾-1½ MODEL A CLEVELAND automatic screw machine. F. T. Coffin, 17 Tudor St., Cambridge, Mass., U.S.A. (2)

FOR SALE—75 H.P. CANADIAN GENERAL Electric motor, 25 cycle, 3 phase, 550 volts, 950 R.P.M.. In first-class condition. Box 258, Canadian Machinery. (26)

1 VERTICAL, SINGLE ACTION, DOUBLE cylinder hydraulic pump, 6" stroke, all ready to connect up; almost new; price $75. McGregor & McIntyre, 1139 Shaw Street, Toronto. (tf)

FOR SALE—FIFTEEN HEAVY CAST IRON columns, from thirteen to seventeen feet long. Columns tapered and have good heavy base and top. Also four roof trusses. Sixty feet long. Ten feet in centre, eight foot at ends. Will cut columns to suit purchaser. Woodside Bros., Port Arthur, Ont. (2)

1—2-SPINDLE SHAPER, WOOD TOP, JOHN Ballantyne, Preston, make, used two months. 1 Dynamo, 45 lights, Toronto and Hamilton Electric Co. make. Used five months. Good as new. Box 195, Jordon, Ont. (R.T.F.)

FOR SALE—1 40 H.P. ROBB, ARMSTRONG high-speed engine; 1 4 x 1 Marsh deep well steam pump, and 1 Barton generator, 80 lamp capacity, with switch-board. All in good order and cheap for quick sale. Richards-Wilcox Canadian Co., Ltd., London. (20)

FOR SALE—TWELVE H.P. GAS OR GASOLINE Engine. Goold, Shapley & Muir Ideal. In first-class condition. Cheap. Stedman Brothers. Ltd., Brantford, Ont. (21)

DOUBLE-END FEATHERSTONE AXLE cutting off machine with countershaft and equipment adapted for cutting off two 4.5 forgings at once. Bargain $500. Medicine Hat Pump & Brass Mfg. Co., Ltd., Medicine Hat, Alberta. (tf)

FOR SALE — ONE 100 H.P. LINCOLN motor, 220 volts, 3 phase, 25 cycles, 750 r.p.m., complete with base and starting compressor, but without pulley. New. Electro Metals, Ltd., Welland, Ontario. (3)

SHRAPNEL SOCKET AND ADAPTER machinery, turret lathes, boring machines, cutting-off machines and thread millers tooled for operation. Globe Electric Machine Co., Hamilton. (tf)

FOR SALE, CHEAP—ONE TWENTY-TWO inch by ten-foot bed Porter lathe; compound rest, steady rest, set change gears, large and small face plate, eighteen-inch four-jaw chuck, boring bar, four tool holders and taper socket fitted. New Prague Flouring Mill Co., New Prague, Minn., U.S.A.

2—30 H.P. PRACTICALLY NEW, LATEST type Canadian General Electric Company's 30 H.P., 60 cycle, 550 volt, 3 phase, 900 R.P.M. induction motors, with starting compensators and adjustable sliding base, pulley 14", diameter 8" face. Price $500 each f.o.b. Sarnia, Ont. 1—20 H.P., same as above, pulley 11" diameter, 10" face. Price $390 f.o.b. Sarnia, Ont. H. Mueller Mfg. Co., Sarnia, Ont. (3)

WANTED

WANTED—COMPLETE SET OF DRAWINGS or blue prints of Universal grinder, with all attachments. Box 251, Canadian Machinery. (1)

ONE AUTOMATIC SCREW MACHINE, capacity up to 1-in.; can use machine having had some service. Canadian Matthew-Gravity Carrier Co., 484 Richmond St. west, Toronto. (2)

WANTED—POWER-DRIVEN ROLLER 8' long, suitable to roll ¼" steel plates: state make, condition, time used. Give price and particulars to L'Air Liquide Society, corner First Ave. and Ernest St., Maisonneuve, Montreal.

WANTED—SMALL SCREW-CUTTING ENgine lathe 12" or 13" x 5' or 6' bed, automatic feed, power cross feed, compound rest; must be cheap and lathe in good working order; give full particulars in first letter. J. W. M., Suite 34, Thelmo Mansions, Burnett St., Winnipeg, Man. (24)

WANTED — THE FOLLOWING EQUIPment for 18-pr. H.E. shells:—2 electric or steam baking ovens, 2 painting machines, 1 banding press and pump, 2 band turning machines, 3 sensitive drills for drilling and tapping grub screw hole, 1 Bowser varnish pump, 1 marking machine. Send quotations to Box 253, Canadian Machinery. (24)

REPAIRING

ALL KINDS OF MACHINERY REPAIRED, rebuilt and installed. W. H. Sumbling Machinery Co., 7 St. Mary St., Toronto, Ont.

SITUATIONS WANTED

TOOL MAKER, ACCURATE, GOOD draughtsman, desires responsible position. Box 254, Canadian Machinery. (4)

SUPERINTENDENT, DESIROUS OF change, 18 pdr. shrapnel, and 6" H. E. shells. Box 247, Canadian Machinery. (26)

MECHANICAL ENGINEER, EXPERIenced in eighteen-pounders and six-inch nosed-in shells, with twelve years' drawing office, shop and general experience, will be disengaged shortly. Box 252, Canadian Machinery. (25)

EXPERT FOUNDRYMAN FAMILIAR with all modern foundry appliances, desires position as foreman or assistant in gray or malleable iron foundry. Box 250, Canadian Machinery. (25)

SUPERINTENDENT WITH TWENTY-nine years' broad mechanical experience in different lines of manufacturing desires permanent connection with well known concern in need of a broad gauge man of unlimited energy and enthusiasm; long proven executive ability, strong personality, unquestioned integrity, strictly temperance, positive aggressive character with good judgment; highest references. Answer Box 260, Canadian Machinery. (2)

SITUATIONS VACANT

TOOLMAKERS AND MECHANICS. APPLY Pease Foundry Co., Brampton; Junction 4341. (3)

WANTED—MAN TO TAKE CHARGE OF machine shop doing repair and new work. Must be up-to-date and able to show results. State experience and salary and when you can start. Apply Box No. 257, Canadian Machinery. (26)

FIRST CLASS GRIDLEY AUTOMATIC men wanted to set up Gridley automatic machines, also operators for same, highest wages paid, only first class mechanics need apply. Apply 47 Richmond St. East, Toronto. (24)

WANTED—NIGHT SUPERINTENDENT TO take charge of factory making 4.5 sockets. Apply Box 237, Canadian Machinery.

WANTED — FIRST-CLASS MACHINIST able to take charge of our repair shop. Apply Hull Iron & Steel Foundries, Ltd., Hull, Que. (23)

WANTED—SUPERINTENDENT CAPABLE of taking charge of 4.5 shell factory in central Ontario; must have had past experience on this particular shell, and must be capable organizer. Please state experience, salary required and all other information possible. Apply Box 259, Canadian Machinery. (3)

WANTED—EXPERIENCED MILL WRIGHT and Machinist to take charge of construction and repair work in growing factory. A man who has had experience as foreman preferred. An excellent opportunity for a first-class man. State when you can start, also experience and salary wanted. Apply Box No. 256, Canadian Machinery. (26)

WANTED—EXPERIENCED MECHANICAL Draftsman; one who has had some experience on machine design and factory layout preferred. Apply stating experience and salary desired to the Goodyear Tire & Rubber Co., Bowmanville, Ont. (26)

WANTED — TECHNICAL ENGINEER — steady, energetic, practical, to learn the business and take charge of the operating and construction departments of a firm manufacturing compressed gases, and apparatus to use such gases. Reply giving experience and salary expected to Box No. 255, Canadian Machinery, 701 E.T. Bank Bldg. Montreal. (26)

INDEX TO ADVERTISERS

Preliminaries in Machine-Part Production Methods--I.

By F. Scriber

The efficient production of general machine work of small and medium dimensions demands the employment of a system which, while adaptable to various methods and processes, possesses also the feature of completeness. Preliminary outlines especially, should so exhibit the salient features of the work that each succeeding department can amplify its data in accordance with the ideas of the production manager, consistent with current conditions.

THE purpose of this article is to briefly yet comprehensively describe the preliminary work which precedes the laying out of tools for manufacturing by some of general production engineers. The system selected for description is not elaborate, nor is it an estimator's production method, but merely a plain statement of facts, enlarged upon so as to convey a clear understanding of what the production engineer has in mind for handling a specific piece of work. A production sheet of this type must be an instruction sheet, generally comprehensive, but flexible enough to permit a tool designer or whoever executes the job to work out the details which are sure to arise, and which no amount of deliberation without actually working out the details, could forestall.

Specimen Form

A type of sheet which may be used for this purpose is illustrated by Fig. 1, headed "List of Tools," and followed by name and number of the subject and other reference data relating to the work in hand. The columns headed "Operations" and "Tools Required" are the places of chief interest, and are filled in according to the judgment of the man arranging the work. The first job illustrated is a turret lathe proposition and the method of sizing it up is shown by the entries made in Fig. 1. We find that the name of the subject is a flange pulley No. 1012; under material, the subject is made of cast iron, and is to be machined on a turret lathe, while the sketch of the

turning, facing, boring, reaming, etc. In the column headed "Tools Required," a brief description or a sketch where this is thought advisable is shown. To enumerate these tools we note that special chuck jaws are required for gripping and a sketch showing the type is drawn in the column. All other tools used for machining this part are standard, and the brief description, such as standard turning, facing, etc., are terms which are readily recognized by men in the habit of working on these machines, while the term cross-slide block is, of course, quite familiar. Where the block must contain a number of tools this must be made special and, therefore, a sketch of this is shown in the "Tools Required" column, with five tools in it, namely, the crowning tool A, the flange rounding tools B, and the rim facing tools C.

In the "List of Tools," Fig. 2, we note the name of the subject is sliding gear, No. 904, made from a mild steel forging in two operations on a turret lathe. A sketch of the subject shows the general construction of this gear, and as the operations and tools required are fully descriptive, the illustration makes the method of handling this part clear.

A Piston Example

A typical example showing tools for use on a turret lathe is illustrated by Fig. 3, and it will be noticed in this connection that the column on the right, "Tools Required," contains a number of sketches. The part to be machined is a piston, and the heading is filled out in the usual manner. The piston is machined in two operations; at the first operation the open end A is bored, which serves to centre the part for the second operation. The machining is accomplished by gripping the part by the closed end in a three-jaw chuck and using standard boring tools in the turret. At the second operation the piston is located on a spindle nose fixture by the end previously bored. Through the wrist pin hole B, cross-wise of the piston, a pin is inserted, passing through a draw back rod, which goes through the spindle of the machine and holds the piston securely in place on the spindle nose fixture when tightened.

The tools which machine the piston are, of course, enumerated in the "Operation" column, and are headed, first, second, third, turret faces, etc. In the column headed "Tools Required" it will be noticed that it is necessary to use specially piloted turning tools. This is necessary owing to the fact that the turning tool pilot cannot be run through the spindle, which is the usual method of piloting on many turret lathes. As special cross-slide blocks are used for grooving the piston, a sketch of these is also inserted in this column.

FIG. 3.

IMPORTANCE OF UNIFORM DRIVING IN TEXTILE MILLS*

By Prof. G. F. Charnock.

THE money value of uniform turning and of close speed regulation in the driving of textile machinery is not appreciated as it ought to be. Steadiness and regularity of driving is an important factor in determining the maximum speed at which machinery may be run with the highest degree of efficiency. Uniform turning of the spindle is essential to the production of an even and level yarn, whilst in weaving, steady turning of the loom is of great importance in reducing the risk of broken threads. It will be recognized that for spinning and weaving machinery there is a maximum speed which the material will stand, and which must not be exceeded. To ensure the maximum output it is, however, desirable to approach this critical speed as closely as possible during the whole time the machinery is at work. The amount of yarn or of fabric produced depends upon the average speed, and the maximum possible efficiency as regards output would be reached when the average and maximum speeds coincide. The adjoining figure illustrates this point.

Taking a base line AB, a line CD is drawn to represent the maximum speed which must not be exceeded. Suppose the variation in speed occurring during the running of certain machinery amounts to 12 per cent., a figure which is frequently reached in the case of looms. At certain periods, the speed then falls to a minimum represented by the line EF, the fluctuation being shown by the wavy line of the diagram. The average speed, indicated by the line GH, will be

$$\frac{100 + (100 - 12)}{2} = 94 \text{ per cent.}$$

of the maximum, and so far as output is concerned, the efficiency might be stated at 94 per cent. Suppose now that it is found possible to reduce the speed variation from 12 per cent. to 4 per cent., the minimum speed is then given by the line IJ, and the curve between CD and IJ shows the fluctuation in speed between the extreme limits. The average speed is, therefore KL, or

$$\frac{100 + (100 - 4)}{2} = 98 \text{ per cent.}$$

of the maximum, and the output has been increased from 94 per cent. to 98 per cent., or

$$\frac{98 - 94}{94} \times 100 = 4.2 \text{ per cent.}$$

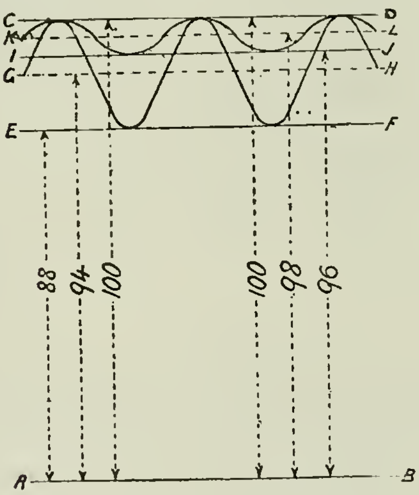
If the speed variation could be reduced to 2 per cent.—an extremely doubtful contingency — the average would be 99 per cent. of the maximum speed and the increase in output as compared with the first case would be

$$\frac{99 - 99}{94} \times 100 = 5.3 \text{ per cent.}$$

If it were possible to do away with speed variation altogether, the average speed would be 100 per cent. of the maximum, and the increase in output, as compared with a 12 per cent. variation, would be

$$\frac{100 - 94}{94} \times 100 = 6.3 \text{ per cent.}$$

This is, of course, a saving which is quite impossible of achievement in practice. Nevertheless, claims to effect an increase in output due to the cause named, and of much greater amount, in some cases as much as 30 per cent., have frequently been put forward. It is evident that such a result cannot be obtained, even in the case of a notoriously bad drive, by reduction of speed variation alone. Where any such saving has



SPEEDS DIAGRAM.

been effected, it is much more likely to be due to a general speeding up of machinery which had previously been allowed to run at a speed much below the maximum permissible. Many such cases exist, and the ease with which a considerable improvement in output may be obtained in this manner is worthy of the attention of every millowner. The gain due to a reduction in speed variation of, say, 3 per cent., does not in itself appear to be a very striking matter, but if the mean speed can be increased 3 per cent. without increasing the maximum speed, this is equivalent per week of 55 hours to a gain of 1 hour and 39 minutes in actual time. Viewed in this light, the problem of close speed regulation is one which no power user can afford to neglect.

*From Journal of Department of Textile Industries in City of Bradford Technical College.

FRICTION CLUTCHES—I.*

By W. G. Gass.

IT is a little difficult to know just where to commence the treatment of a subject like a friction clutch, which is not a machine in itself but only a part of machinery, and of which there is so great a variety, so many makers, and such extended use. It is not therefore proposed to deal with any one type, but to review the general types into which they may be classified, to refer to their common points and detail, and as far as possible their weaknesses and faults; not with the idea of extolling one type against another, but by bringing their faults to view to help towards their removal, for it is only by consideration of weak points that we can strengthen them. It may be taken as an axiom, that though one type of clutch may have advantages over another, there is not any perfect clutch, some types answering better than others for different classes of work; this is a great point to bear in mind when arranging clutch drives.

Clutch Types

We may commence by defining a clutch as a mechanical device by which rotary motion is transmitted from a first motion shaft to another or second motion shaft, which may be either in the same straight line or parallel with it. Clutches are divided into a number of distinct types:—Claw couplings, friction cones, internal segment and band clutches, external segment and band clutches, plate clutches, brush clutches, magnetic clutches, automatic clutches.

Claw couplings cannot be generally classified as friction clutches, but they can be and are combined with a friction slipping device by which some of the shock is absorbed when thrown into gear with the prime mover when rotating. Without any friction they are very useful on machines where the load is not very great, as they have all the advantages of giving a drive with no chance of slip. Where used for transmitting heavy loads, or at high speeds, they should only be put in gear when the machine or shafting is stopped. They are also very difficult to release when transmitting heavy loads.

Friction Cones.—These are the simplest form of friction clutch, and for some purposes the best, because simple in construction; if properly made they drive very well. They have the serious defect for general use of requiring to be held up with a constant pressure, which absorbs power and causes wear on the setting-up gear, with the bear-

*Read before the Manchester Association of Engineers.

ings taking the thrust of the setting-up gear. A portion of the constant thrust can be eliminated by making the angle of the internal portion sufficiently small, but this makes the cones liable to stick, and it is not infrequent, when large cones are so made, to have to hammer the outside of the cone to make the two portions come apart. If, on the other hand, the cone angle is too large, the pressure required to keep the two parts in gear is so great that it is very difficult to transmit the power. Generally these large cones are used for driving machinery in bleach-works and similar places, and are useful where there is a good deal of wet about. They are usually made of cast iron, the inner part sliding on the shaft on float keys, the outer part running loose on the shaft. They have been tried as double cones with internal and external bearing surfaces, but there is nothing to justify such an arrangement. If covered with some frictional substance such as leather, or any of the numerous frictional materials made for the purpose, the driving power is increased.

In motor cars the cone has proved a most valuable type, as the usual conditions are reversed, and it is as a constant driver that its value comes in. The arrangement in motor cars is such that there is no end thrust except when it is not transmitting power, and is, therefore, working under the best conditions.

Internal Segment or Band Clutches.—These are divided into two distinct types, those in which the internal segment is in two or more sections, which are forced apart— by means of screws usually, and those in which the internal segment is cast all in one piece, so arranged, that the driving portion is expanded against the spring of the metal. This type is made in two forms; in one case the segment is sprung apart in two points, and the other in one place only. Similar forms are made with hinged portions. In the loose segment type, the segments are carried on the arms of a turned internal piece, usually keyed on to the shaft as driver, but in other cases sliding in grooves made to receive them in the driven portion.

The External Segment or Band Clutch, is made in quite as many forms as the internal band type, but is more generally used for the smaller powers. The segments are in two, three or four pieces forced on to a central drum and carried in much the same way as the previous type. A single band similar to brake drum strap gripping on a central drum and set up by a wedge is one form; another has two bands and is set from opposite sides. Another takes the form of a spring coil which tightens up by tension and friction, and is, in fact, an external cone clutch with a flexible rim. It is not usual to consider a fast and loose pulley drive as a clutch, but it comes under this head, the belt being the external friction band.

A Plate Clutch is distinct from any of the other forms, as the gripping surface is between two or more flat plates pressed together, one plate being attached to the driver and the other to the driven alternately. These are forced together by levers through a toggle joint. Another form of this type has the plates of stamped steel formed into a kind of double cone, which is supposed to give it extra gripping powers.

Brush Clutches.—These utilise the resistance of a great number of projecting wires, which when the two portions are pushed together, interlock and give the necessary power of driving.

Magnetic Clutches have generally two flat faces, though conical surfaces have been used, which are pulled together by the power developed in an electro magnet formed in one half the clutch.

Automatic Clutches depend on centrifugal action to keep the surface in contact, and are used in connection with electric motors, being designed usually to come into operation at certain desired speeds. The foregoing brief summary of the different types makes it evident that their number is very great, and that it would take more than the space available to describe them in anything approaching detail. They, however, all possess good points and faults in common, and it is these which it is proposed to consider as well as their other features in what follows:—

Driving Surfaces

These are for the most part metal on metal, usually cast iron on cast iron. In cones, and in internal segment clutches, in the old days they used to be covered with copper plates riveted on by copper rivets. Many of the oldtime millwrights, particularly in bleach and similar works, would not have anything else, but there are not many made so at the present time. Copper covering did not materially increase the driving power, but it was generally believed to do so. If the clutch were heavily loaded there was a tendency for the copper to creep and shear the rivets. Examination of the surface of the copper after long work showed the surface to be embedded with fine particles of iron from the outer part of the cone or clutch, and it became hard and glazed, the pieces of embedded iron being hard and exceedingly sharp.

There are several kinds of friction material now made which are recommended for clutches. These, no doubt are of advantage for brakes, but there are difficulties in the way of using them for clutches. In most cases rivets have to be depended on, and these are apt to give way. The material is liable to glaze, particularly where the clutch goes in and out many times. Wooden blocks as driving surfaces act very well if the load is not excessive, but if overtaxed they char on the surface and give way. Where steel is used it should not rub on cast iron unless its surface is chilled very hard, or, if on steel, on a casehardened surface. Some of the smaller kinds of clutches use two hardened surfaces, but this must reduce the driving power.

In plate clutches, cast iron on cast iron is, in the author's opinion, best, mild steel on cast iron being a failure. One clutch uses a double cone arrangement in which the pressure is on the inside and the outside, and steel plates are used throughout. A great deal is claimed for this, and it is satisfactory as long as it is attended to and not overloaded. In motor cars, leather faced cone clutches are in the majority, and the results justify their popularity; they have to work so much as a slipping clutch that metal to metal surfaces have not proved satisfactory unless lubricated. In these, the co-efficient of friction is of course higher than metal to metal. In magnetic clutches, fibre on iron is usual, and they are said to give good results.

The trouble of driving surfaces is that they wear away, and this wearing is greater or less as the clutch slips or not. It is obvious that faces of metal cannot slip on one another under pressure without wearing away, and the examination of surfaces which have been in use shows the way in which the loss occurs. The surfaces generally being dry, a small portion of metal gets embedded into whichever of the surfaces is the softer, and acts as a kind of plough into the other. It is not necessarily the softer of the two which gives way, but often the harder. This does not sound quite reasonable but it is a fact. If you take a lead plate and cover it with particles of emery it will cut away the hardest steel. It is not, of course, the lead plate that cuts but the emery. The same thing occurs with the clutch; particles of hard material get embedded in the softer and act as the cutting material, but only when the clutch is slipping, so that the wear may be slow or fast depending on whether the driving faces slip much on each other. This explains why clutches put in as slipping clutches are not often very successful.

SOME OPERATIONS IN THE MANUFACTURE OF SAWS

By D. A. Hampson.

SAWS of all kinds are so common and so good that users of them take their good qualities as a matter of course and men in the mechanical trades seldom, if ever, give thought to the many processes required to produce them. There are very few of the tools and appliances and machines in use in such profusion to-day, and to which we owe so much, that could not be duplicated in any well equipped machine shop with a fair degree of success, if the shop had to do it but to turn out only one or two saws would be practically an impossibility.

A Specialized Line

Saws are made in a few plants only as their manufacture requires an equipment so extensive and expensive that only specialists with an enormous output can "make a go" of the business; specialization and quantity manufacture are directly reflected in the low prices which saws bring in the open market.

The manufacture of hack saws, butchers' saws, etc., is usually a separate business from the line of heavier saws for carpenters, lumbermen, and ice men and is usually carried on by specialists in that finer grade of work. Considering these larger saws, the steel of various "gauges" is received from the rolling mills in sheets and is cut up in shears, slitters, and punches to the required sizes and shapes. The various processes in manufacture might be named in their order—cutting to shape, punching the teeth, grinding the sides, filing and setting the teeth, hardening, glazing or polishing, putting on handles, and packing.

Press Work

Punch and die work enters largely into the saw business. All the teeth are cut in this manner. In the case of hand saws and the like having a straight-cutting face and a uniform shape and spacing of teeth, the punch press is provided with a feed and all that the boys tending the machines have to do, is to put in the blanks—in shop nomenclature these saws are cut 8-point, 14-point, etc., according as they have 8 or 14 teeth to the inch. It will be inferred that the punch and die making department in any saw plant is a most important one; the work is hard on the tools for while saw steel does not average over 3-32 in. in thickness, it is tool steel of the best grade and the blank steel is punched in a black state with more or less scale on. Punches and dies are made as in all general practice. Punches are made to give about 2½ in. of length to use up in grinding and with this length have to be well backed up for stiffness. The clearances between punches and dies is made quite large partly because of the unskilled labor that sets the machines.

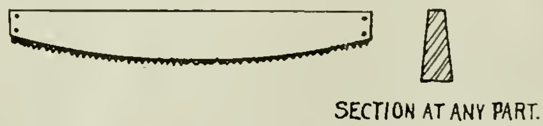

FIG. 2. CRESCENT SAW.

Grinding

Saw grinding is one of the special operations that is of more than passing interest. All the grinding is done wet on Ohio grindstones of varying face widths that start in at a diameter of 6 feet and are worn down to 2½ feet, a stone lasting from two to four weeks. The stones are mounted on a heavy arbor supported in the side frames of the machine and driven by two long belts, one on each side. It is common practice to drive all the grinders from the line shaft S running along the wall at the back of the room, Fig. 1. Grinding requires a great deal of power and not infrequently one engine drives nothing but the grinding department shafting.

The saws are ground on top of the grindstone and by passing through and back much as the steel itself was rolled. The necessary downward pressure is obtained by passing the saw under a cast iron head block H directly over the highest point of the grinding wheel; pressure is regulated by screws on the head block connected through bevel gearing to the hand wheel W, which is large enough to be within the operator's reach as he stands on his platform. The wheel is dressed off perfectly straight and the head block ground to it—so the saws come out with a uniform cross section throughout. As the grinding pressure used is heavy, a powerful feed is required which takes the form of two pairs of rollers R. R. carried in bearings, adjustable vertically, in the side frames and driven from the main shaft.

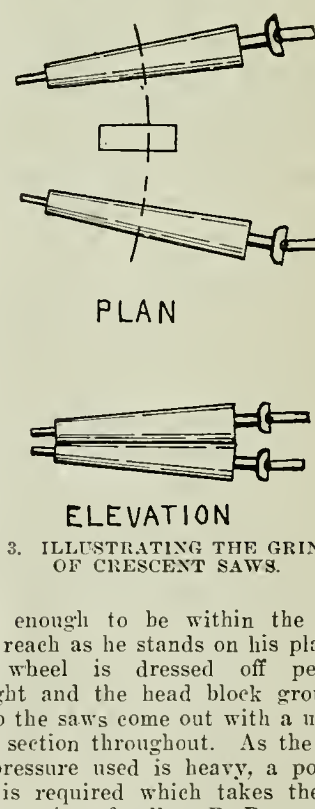

FIG. 3. ILLUSTRATING THE GRINDING OF CRESCENT SAWS.

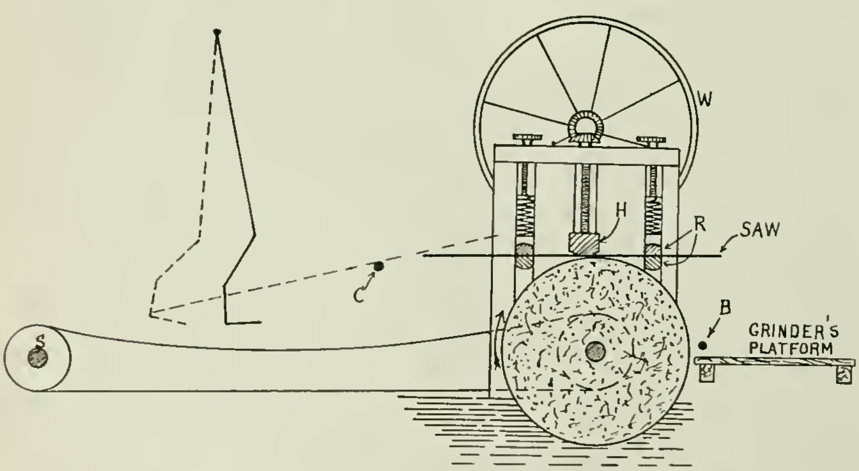

FIG. I. DIAGRAM ILLUSTRATING PRINCIPLE OF SAW GRINDING MACHINE.

Handling Work and Dressing the Stone

The method of dressing the stone and of returning the saw to the front of the machine are worthy of notice—so good and yet so simple as to be almost primitive. When the stone gets dull or out of shape, the grinder removes his platform, drops a bar B into sockets in the frame, and uses a piece of ¾ in. or 1 in. ordinary pipe for a dresser. To do this, he has to straddle the pit of water and put on a leather suit completely covering him from head to foot which is highly necessary for as he "goes to it" with the pipe he becomes enveloped in a cloud of dust and mist. From that cloud he emerges in ten minutes with his crude implement and a wheel straight to a thousandth thanks to that intangible thing called skill. Formerly it took two men to a machine, the grinder and his

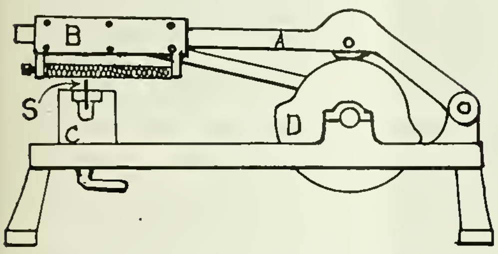

FIG. 4. SAW SHARPENING MACHINE.

helper who "back tended" (passed the saw back over the rolls) but a studious fellow conceived the swing which is now used. This is made from a piece of sheet iron 36 in. square, and hung from the ceiling in such a position that the saw being fed through shoves it beyond its center and as it leaves the rolls it drops in the swing and lays over the rod C. The return of the swing to normal brings the saw within easy reach of the grinder.

Crescent Grinding

A departure from the grinding to uniform thickness may be found in what are called crescent ground saws—saws having a convex cutting edge with relief ground back equally from all parts of it. Some ice saws are this way, lumbermen's cross cut saws are now generally ground that way, and so are some others. This crescent ground relief is in addition to the set of the teeth and makes a very easy running saw for green wood, etc., etc.

The arcs of the cutting edge of these saws are of different radii, a fair average being 15 feet. To get this effect two pairs of tapering feed rollers are used on a regular grinding machine; these are set so that all lines on their surfaces would converge at a common point—the center from which the arc is drawn. Universals drive the rollers and the head block is set to bear more heavily on the "in" side, of course to be theoretically correct a set of rollers will do for only one size of saw, but with the aid of a gauge for grinding the saw when fed to the rollers, saws of different arcs can be crescent ground quite accurately, Fig. 3.

Saw Filing

The greatest labor saver ever introduced was the successful saw filing machine which came with the latter years of the last century. Before that, in every saw plant could be seen long rows of men and boys, filing saws for dear life, who made big money at piece work before the manufacturers included a limited file allowance in the price and adopted more rigid inspections. As the teeth are punched, they are straight across and have a rough sheared surface which must be filed smooth and at an angle. To-day all saws are machine filed except specials and samples of certain classes.

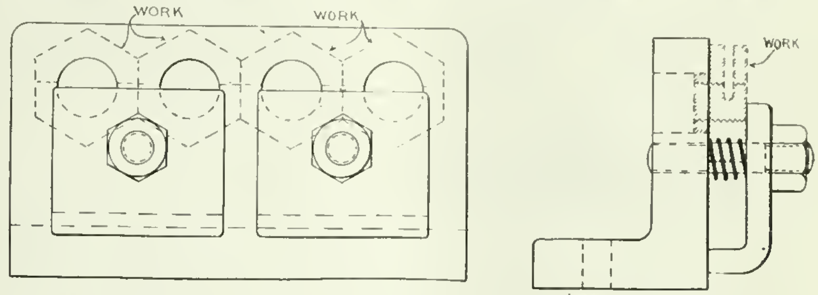
Though the machines for filing larger saws are quite large and elaborate, the bench machines employ the same general principle and are simpler to illustrate. They have many points which make them similar to the power hack saw. In bearings on top of the frame runs the drive shaft having at one end the disc D, which acts as a cam and a crank, Fig. 4. The crank pin and pitman drive the file holder B back and forth on the arm A which is raised on the return stroke of the file by the cam face of D and the cam roller. The saw S is held in a pair of grips which slide in the swivel block C which is set for the angle of the teeth. The file is held at an angle that is sufficient to move the saw one tooth at each forward stroke—no better feed could be desired. The tight pulley is on the main shaft and is always running, a simple pin clutch throwing it into gear. As alternate teeth are filed to the opposite angle these machines are run in pairs and the saws taken, still in its grips, from one machine and placed in the other to be finished.

The operations of hardening, straightening, and setting are all full of interest as is also that of handle making. Taken right through the operations and processes are the result of long study and experiment and produce to such a degree that they may well be copied and modified to suit conditions and work in other fields of mechanical endeavor.

MILLING FIXTURES FOR SMALL JOBS

By W. G.

TWO simple milling fixtures are shown in the accompanying illustrations, Figs. 1 and 2, being a useful arrangement for cutting the spanner slots in circular nuts and other similar work. Ample rigidity and ease of operation are features of the design. The upper portion of the casting A is bored to receive the work spindle B, which is made a close fit in A, and has a collar formed at its centre in which a number of holes are drilled for the use of a small tommy bar when turning round. A dividing plate C is keyed on a

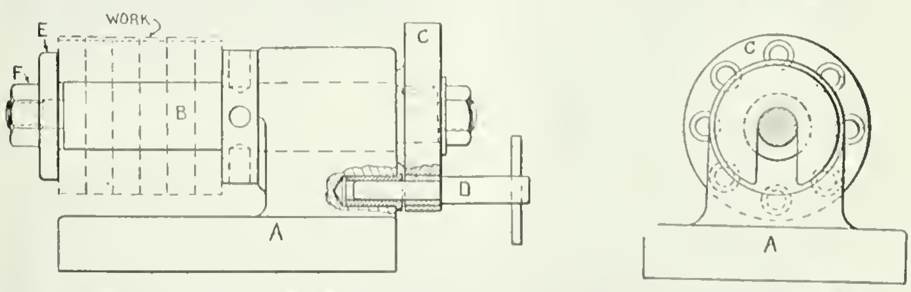


FIGS. 3 AND 4. FIXTURE FOR SLITTING HEXAGONAL NUTS.

reduced diameter and held in place by a washer and nut, the distance between collar and dividing plate being accurately adjusted to the length of hole in casting A. Hardened steel bushings are fitted to the dividing plate, which is held in the desired positions by pin D, passing through each hole in succession and engaging with a bushed hole in casting A.

The work, shown in dotted outline, is held on the other end of spindle by a slotted washer E, and nut F, care being taken to make the diameter of the nut across the corners slightly smaller than the spindle diameter. By so doing, the work can be slipped over the nut, washer E dropped into place, and the whole tightened up against spindle collar, the work being removed in the reverse manner.

The fixture shown in Figs. 3 and 4 was gotten out to increase the output of slit lock nuts such as are used on certain classes of electrical work, these having formerly been cut one at a time in a machine vise. A substantial cast iron angle was machined accurately on the bottom face and one side, and four holes drilled through the vertical web, these being accurately spaced so that the hexagonal nuts located themselves as shown. Two studs were then inserted in the positions shown and fitted with clamp plates for



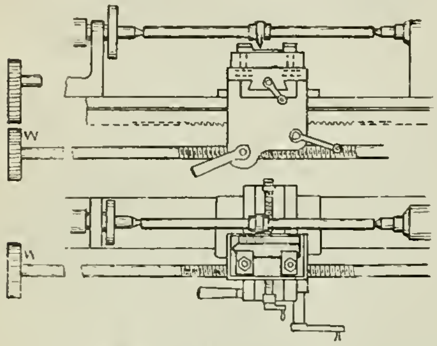
FIGS. 1 AND 2. FIXTURE FOR CUTTING SPANNER SLOTS IN CIRCULAR NUTS, ETC.

each pair of nuts, a spring being fitted on each stud for the purpose of making the clamp plate follow up the nut when slackening back so that the work can be easily removed and replaced.

GRADUATING A GAUGE IN THE LATHE

By E. T. Spidy.

SOME years ago during his apprenticeship the writer had occasion to graduate a gauge in course of making, and conceived the idea of using a tool lathe for



GRADUATING A GAUGE IN THE LATHE.

the purpose, no special appliances being available for the work. The manner in which it was accomplished is shown in the sketch. An old milling cutter was specially ground to a point and mounted between the lathe centres, being prevented from rotating by a dog (not shown) on the shaft. The top tool clamp was then removed and the gauge clamped in place. With the guide screw securely locked in the split nut and with a lead screw having four threads per inch, it was possible to secure very accurate spacings by turning the wheel W through a quarter of a turn, causing the carriage to move along 1-16th in. with a considerable degree of accuracy. The actual marking of the graduation made it necessary to run the cross carriage in and out each time, but where one's tools were limited, the arrangement described makes a good and accurate job.

RELIABILITY OF PRODUCT

AMONG the cardinal virtues which underlie all business and manufacture, there is absolutely nothing which can compare in importance with that of reliability, because, to say that a certain article, machine or man is reliable, is to pass the highest compliment known to mechanical art. Lots of quite surprising novelties whose interest and possibility were instantly recognized have passed into oblivion, not because they always failed, but that no real dependence could be placed upon them. Part of the conservatism and prejudice met with, acting adversely to the introduction of the new, is due to past unreliability of equally promising schemes.

Argument from first principles will not do; there must be conviction that uniform results may be expected. Trying out is one way of phrasing the search for dependable results; guarantees are another means of convincing a customer. There is merit, but little value, in a single piece of steel with extraordinary virtues; if, however, it can be duplicated in large quantities, the desired ends, uniformity and reliability, are secured.

The average engineer is a sceptical person, hard to convince, slow to introduce the new and abandon the old; he has experience of existing things, knows they are reliable, while the new must be tried out before it can prove successful. Nothing succeeds like success, but the cardinal feature of success is dependability. It is extremely galling, after one machine has been installed, to find its duplicate troublesome, hence the need for a manufacturer to take real pains to secure uniformity of product. Ingenuity, good design, attractive features, may all be sacrificed by default in material or workmanship, or the feeling that near enough is good enough. It isn't. The first-class maker incurs large expenses in testing his product to secure reliability, to insure real duplication, to locate and remedy trouble and error before despatching the goods. Such methods secure that easily forfeited but coveted distinction—reputation. A house of repute may have its products flagrantly copied and still suffer little by such competition. Unless the competitor has the same conscientious scruples as the originator (obviously he hasn't), then his product must be inferior in what counts in the long run above all else—reliability.

To attain the reputation enjoyed by some of the progressive firms of to-day means constant vigilance and unremitting watchfulness that the material, workmanship, and other minor but equally essential things do not suffer. It is in one sense easier to build a reputation than to hold it, easier still to live on the reputation of the past slowly sinking into decay, than it is to rest unsatisfied, and while maintaining vital characteristics, to continue the upward climb of progress. Eternal vigilance is the price of most things worth having, and in the business of engineering it is exacted to the uttermost. When a first-class article is bought from a house of reputation, this quality is included, but not invoiced.

It seems simple enough to build a standardized machine in quantities; good methods and practice economically sound are fairly well known; staff and workmen competent for their various duties can be hired at market rates, but more is involved even than method, men and organization; there is always that administrative supervision which counts for so much. Reliability will not take care of itself—it depends upon too many factors; hesitation to scrap the imperfect is a common failing, and the invasion of slovenliness is difficult to check.

In a human sense a reliable man is a dependable man, always there with his job on hand at the right moment, indicating initiative, character and backbone. Such men are not common. The raising of such men depends as much upon what the management does as upon any system of reward. There must perforce be the native material to begin with, but one indication and measure of the value of any firm is in the type of man they train. Anyhow, it is difficult to see how reliable products can be built without reliable men.

If the material turned out has character, it is equally certain that the builder thereof has character too. In such-wise, reliability has a double effect, and its reaction from machine to man and conversely is worth consideration. Dishonest and slipshod methods of workmanship have a human no less than a material aspect. Reliability is itself a complex quality built up of numerous but quite ordinary virtues, co-ordinated, however, into a combination whose value is not easily assessed. Vigilance is its price, involving unremitting labor and thought, but its reward is sure.

LUMBER ORDERS FOR B. C.

LARGE contracts for lumber, aggregating 16,500,000 feet, exclusive of an open order for all the clear spruce available, has been placed by the Imperial Government with British Columbia mills.

Victoria, Vancouver and Chemainus mills will supply two cargoes of railroad ties ordered by the British Admiralty through a San Francisco house, this order approximating 7,000,000 feet.

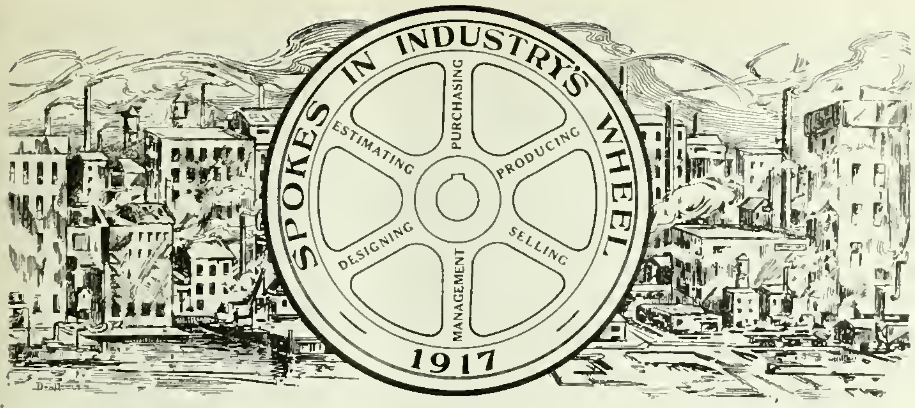
Another order has been placed direct by the British Government for 3,500,000 feet of lumber, 2,000,000 feet of which will be clear fir, the remainder being heavy timbers, which will be shipped through to St. John, N.B., and handled from that point by British transports.

In addition, a third order has been placed by the Admiralty for 500,000 box shooks, approximating 6,000,000 feet, this order being divided between the Brunette Saw Mills and B. C. Manufacturing Co., of New Westminster; J. Hendry & Co., Vancouver; Lemon & Gounason, Victoria, and the Cameron Mill Company, also of this city.

The total output of clear spruce for airplane manufacture and shipments are being sent overseas as fast as the mills can supply this class of lumber. The new orders are welcomed by the mills, not from the profit standpoint, as the prices are about as low as it is possible to handle the business, but because the placing of these contracts with the British Columbia mills will assure steady operation for some months to come.

NEW BRUNSWICK MINERALS

THE minerals of New Brunswick, developed and undeveloped, cover a considerable range. They include an antimony deposit at Lake George, which has recently been taken over by the Northern Antimony Smelting Company, with a capitalization of $2,000,000; bituminous coal deposits (estimated to contain fifteen million tons); iron, gypsum, oil shales, manganese, graphite, tungsten, molybdenite, copper, lead, zinc, galena, barytes, infusorial earth, black, grey and red granites, freestone, sandstones, and other minerals, which offer a very attractive field for investment. A discovery of a rich bed of galena ore was recently made at Maple Grove, York County, by W. H. Griffin, a provincial game guide. Two veins of 22 feet and 12 feet respectively have been uncovered. Ontario parties have secured an option of the mine.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

D. M. MEDCALF

WITH the new Steam Boilers Act, which became effective throughout the Province of Ontario on July 1, 1913, there arose the necessity to establish a fully equipped bureau of inspection, and, in casting about for a responsible head for same, D. M. Medcalf, who, during the previous eight years had been provincial inspector of boilers and operating machinery installed in our public institutions, received the appointment. Constituting what is officially known as the Steam Boiler Section, Trades and Labor Branch, Department of Public Works, Province of Ontario, and occupying a suite of offices in the Parliament Buildings, Queen's Park, Toronto, we find a staff personnel of one chief inspector—Mr. Medcalf, six inspectors, one stenographer, and one clerk and stenographer; a by no means formidable aggregation when account is taken of the onerous nature of the duties imposed, and of the myriad industrial and power plants, public institutions and office buildings, portable and semi-portable outfits, etc., into the activities, of which steam boilers, steam piping and the numerous auxiliaries of the latter, enter.

Mr. Medcalf was born in Toronto, March 19, 1873, of Canadian parentage, receiving his education in the public schools of his native city. At the age of sixteen—like most boys, he found school life a trifle slow and unromantic, having figured that by donning overalls and applying his then acquired education, he could not only continue to learn, and to perhaps greater ultimate advantage, but what was of equal importance, begin to earn something for those on whom he had been so long dependent, besides securing a modicum of pocket money for himself. We find him, therefore, in 1889 an apprentice machinist in the Don Foundry & Machine Shop, Toronto, formerly owned and operated by his father, the late Alfred Medcalf. Later, he transferred his services to the Polson Iron Works as a machinist improver, and completed his five years' apprenticeship in that capacity.

It is generally believed, and shall we say there is all truth and little fiction in the statement that, making due allowance for the fact of other and perhaps farther away fields looking greener, newly full-fledged mechanics, however expert, must flee the apprenticeship nest

D. M. MEDCALF.

in order to secure a cash rating commensurate with their ability. Be that as it may—although all of us are unanimous in our opinion, we find young Medcalf employed as a journeyman machinist first with the John Inglis Co., Strachan Avenue, Toronto, and some time later with the Northey Pump Works, also of Toronto. We next find him in a like capacity employed for stated periods in the Vulcan Iron Works and C. P. R. Shops, Winnipeg, Man. The lust for travel, no less the quest for experience, engendered by the journey to and sojourn in Winnipeg, may be taken as ample reason and justification for our hearing of his having crossed the border and taken up his abode for what ultimately proved to be for a period of six years' duration.

During this time he was successively employed as a mechanic with the Lake Erie Engineering Works, Buffalo, N.Y.; Baldwin Locomotive Works, Philadelphia, Pa.; Northern Pacific Railway Shops, Brainard, Minnesota; and Illinois Central Railyway Shops, Chicago.

Mr. Medcalf, in December, 1909, represented the Province of Ontario at a conference of Provincial Boiler Inspectors held at Regina, Sask. There, rules and regulations were drafted and subsequently adopted by the Provinces of Alberta, Saskatchewan, and Ontario. Since then, steps have been taken towards a further development of uniformity in provincial boiler construction and inspection rules, and it is reasonable to assume that at no distant date all of the provinces of this Dominion will see it to be advantageous to fall into line. In what has already been accomplished, and in the coming consummation of a Dominion-wide code of boiler rules and regulations, the personal effort and untiring energy of Mr. Medcalf will be found to have been in large measure responsible.

Mr. Medcalf married Ella Clemens, of Preston, Ont., in the year 1900, his family consisting of two, known in the writer's native country as a "Do'e's Cleekin." His recreations are motoring and bowling—when opportunity permits, although from what we know of the gentleman, his recreations—or more properly speaking, his hobbies, are largely in the realm of boilerdom. In a word, his new position, onerous as are its duties, seems to serve admirably, both as a life business and an all-absorbing recreation or hobby. Due to holding a Government appointment, he has had to abjure politics, not an over-hard undertaking on the part of the engineering fraternity, as was here remarked on a former occasion. In matters of religion he is Methodist, and, according to his own statement, which we can vouch for—the statement only, of course—he is regular and dutiful in his attendance at services and in the activities respectively of the Eaton Memorial Church, Toronto. We may not omit, however, to state that Mr. Medcalf has not altogether overlooked his fraternal obligations, expression being given same by his A.F. & A.M. membership. His residence is 51 Parkwood Avenue, Toronto.

Technical education, through the medium of specially established schools, or home study supplemented by technical books, trade and technical papers, finds in Mr. Medcalf a booster at once high grade and effective, a circumstance due, we should say, to the fact that through its instrumentality and ramifications he owes perhaps as much as to anything else his present appointment, as well as the ability with which he directs and supervises its many-sided activities.

BOILER INSPECTION REPORT, DEPT. PUBLIC WORKS PROVINCE OF ONTARIO

THE enormous increase in the cost of steel since the outbreak of the war has affected to a considerable extent the manufacture of boilers in Ontario as elsewhere by reason of the necessary increase in the selling price. This increased cost of new boilers has created a great demand for secondhand boilers—not altogether on account of cheapness for high prices are being paid—but by reason of their being more or less immediately available. Many old and discarded boilers which in normal times would be sold as scrap or left rusting in vacant places around our factories have been cleaned and painted and put on the market for sale by boiler dealers, a circumstance calling for extra vigilance as far as inspection goes.

A slight alteration has been made in the Steam Boiler Act, section 2, subsection D, which formerly read:—

"A portable boiler rated at 25 horse power or under, or a boiler used exclusively for horticultural or agricultural purposes." The words "rated at 25 horse power or under" have been omitted. This change in the Act gives jurisdiction over portable boilers used in public places in conjunction with contractors equipment etc. Boilers of this kind formerly were not built from registered designs and were exempt from provincial laws. The fact that those boilers are often used in close proximity to hundreds of people is good reason why their designs should be of the most approved type, and also why they ought to be inspected annually.

It will be noted from the list of inspections that in addition to boilers, a number of air tanks have been examined during the past year. This inspection work was made at the request of the owners of these vessels and the customary fee of $5.00 per tank was paid by them. The safe working pressures were determined from the rules governing the construction of steam boilers, and the same certificates as issued for used boilers were made out for these vessels.

During the past year ten boilers have been inspected for British Columbia. Arrangements were made during 1915, whereby the inspection of all stationary boilers built in Ontario for British Columbia would be carried out by Inspectors of this branch. Some trouble was experienced heretofore by manufacturers on account of their boilers being re-examined on arrival at their destination, and sometimes the safe working pressure was reduced on account of defects in the workmanship. The boilers examined during the past year have been accepted by the British Columbia authorities without being penalized in any way. During normal times the number of boilers built in Ontario for British Columbia would of course be much more than last year's total.

For some time past, and more especially since the fatal steam valve explosion at the Greey Foundry, Toronto, the work of surveying and registering high pressure pipe lines has been undertaken. The accompanying data summarises the inspection work carried out during the year ended October 31, 1916.

Drawings and Specifications Surveyed and Registered.

Boilers	97
Boiler fittings	78
Pipe lines	31
Pressure tanks	6
Digestors	4
Superheaters	1
Drawings returned to manufacturers for correction	17
Registered boilers inspected during construction	313
Plates examined	1415
Plates rejected	16
Registered boilers inspected by Insurance companies in the United States	35
Registered boilers inspected by Insurance companies in Great Britain	4
New boilers inspected during construction for British Columbia	10
Used boilers inspected in Ontario	612
Air tanks inspected in Ontario	21
Steam drums inspected in Ontario	4
Steam plans inspected in Ontario	1
Pipe lines inspected in Ontario	4
Used boilers inspected and condemned	23
Class "A" certificates issued for new boilers	348
Class "B" certificates issued for used boilers	527
Heating certificates issued	220

BRITAIN'S MUNITIONS OUTPUT

THE remarkable increase in Great Britain's output of munitions is dealt with in an official statement just issued, which says:

"From time to time indications have been given of the enormous growth in the production of munitions in this country during the past 18 months. The supply of both guns and projectiles is increasing, as will be seen by the following figures, in which, from its importance in modern methods of warfare, artillery ammunition deserves first place. Taking as a basis for calculation, the average weekly production from the beginning of the war up to the end of June, 1915, the figures show the following wonderful rate of progress:

	(a)	(b)	(c)	(d)
18-pdr.	1	6½	17½	43
Field Howitzers (4.5 in.)	1	8	27	
Medium guns and howitzers	1	7½	34½	66
Heavy Howitzers (above 6 in.)	1	22	94	333

(a) Weekly average at the end of June, 1915.
(b) Weekly average from July 1, 1915, to June 30, 1916.
(c) Week ending July 1, 1916.
(d) Week ending November 25, 1916.

"The improvement may be illustrated in a different way. We are now manufacturing in 8½ days the number of 75 m. m. shells which we were producing during the first year of the war—August, 1914 to August, 1915. The same quantity of projectiles for field howitzers is being supplied in eight days; that of projectiles for medium guns and howitzers in 5½ days, and that of projectiles for heavy guns and howitzers in a little more than one day. The number of shells completed or filled during the week of November 19-26 this year exceeded by about 30 per cent. the stock of munitions, held in reserve at the outbreak of hostilities.

Manufacture of Guns

"Dealing with guns in the same way, it is found that, representing the number of guns manufactured during the first year of war, the following increase has been secured:

	1st year	2nd year	July 31 to Nov. 29, 1916 (4 months)
18-pdr.	100	240	45
4.5 in.	100	654	104
Medium (60-pdr. and 6 in.)	100	1,848	1,200
Heavy (over 6 in.)	100	623	363

"The manufacture of 18-pdr. guns has had to be slackened during the last period, the equipment of the British army in light field pieces being approximately complete.

"If the average monthly production of guns of all calibre be considered, a splendid development can be observed on comparing the results of the first year with those of the second period of 1916, as is seen from the following table:

	Monthly average for first year	Production during the five weeks ending Dec. 2, 1916
18-pdr.	100	128
Medium	100	4,100
Heavy	100	1,250

Large Increases Shown

"The improvement in the manufacture of machine guns, rifles, grenades and explosives has been equally satisfactory. If the total number of machine guns delivered to the army during the first year of the war be represented by 100, the total could be represented by 1,250 at the end of the second year and by 2,000 on December 2, 1916. Taking as a base the weekly production of machine guns in November, 1915, and representing it by 100, the corresponding figure for the weekly production in November, 1916, would be 410.

"The increase in the manufacture of explosives has been extremely rapid. For every ton of explosive employed in September, 1914, 350 tons were employed in July, 1915, and from 11,000 to 12,000 tons in July, 1916.

"Between May, 1915, and May, 1916, there was a 38-fold increase in bombs and a 150-fold increase in the weight of the contained explosive."

Toronto, Ont.—At a meeting of the Board of Trade held recently, John G. Kent was elected president, C. A. Bogert, of the Dominion Bank, vice-president; Charles Marriott, of G. Goulding & Sons, second vice-president, and W. H. Alderson, of the Gutta Percha & Rubber Co., was elected treasurer.

PASSING OF A LEADING CANADIAN MANUFACTURER

IN the death of Hugh McCulloch, president of the Goldie & McCulloch Co., who passed away at his home, Sorn House, on January 8, Galt has lost one of her leading and most highly esteemed citizens.

Mr. McCulloch, who was in his 61st year, was born in Galt on September 7, 1856. He received his education at the Whitby Grammar School and Upper Canada College, on completion of which he served an apprenticeship in the Goldie & McCulloch shops, his father, Hugh McCulloch, sen., being then president of the company. Practically his whole life has been spent in furthering the interests of the firm in which he was a member, and the industrial interests of the community in which he lived.

When the company was incorporated in 1891 and took over the business of the firm of Goldie & McCulloch, he was appointed secretary-treasurer, which position he held until elected vice-president in 1898, assuming the presidency on the death of his father in September, 1910. Mr. McCulloch was closely associated with various other manufacturing concerns in Galt, having been at the time of his death vice-president of the Galt Malleable Iron Co., also of the Galt Art Metal Co., a director of the Gore Mutual Fire Insurance Co., also for many years a director of the Galt Gas Light Co.

In religion Mr. McCulloch was an honored member of Knox Presbyterian Church. His principal amusements were fishing, golf and motoring. Sorn House, his home, constitutes in itself and location one of Galt's beauty spots. There survive him a sorrowing wife, one brother, R. O. McCulloch, of Galt, and a sister, Mrs. Chas. A. Shearson, of Toronto.

The funeral, which took place at Galt on Wednesday, January 10, was very largely attended, the number of local mourners being materially supplemented by friends and business associates from other places.

AUSTRALIAN RESTRICTION ON CANADIAN SHIPPING

THE Canadian Government is now negotiating with the Australian authorities with regard to loadline restrictions at present imposed on Canadian ships trading to ports of the Commonwealth. The matter has become of immediate importance in connection with the construction on the Pacific Coast of wooden ships designed to carry lumber from Canada to the Antipodes. Partly as a result of subsidies by the British Columbia Government, there has grown up in the Pacific Province a wooden shipbuilding industry of considerable proportions. Numbers of vessels of from 1,500 to 3,000 tons are being turned out, being designed as four and five masted schooners with auxiliary Diesel oil engines.

These vessels will enter into competition with American-built ships, which trade to Australia and which have hitherto carried much Canadian lumber as well as pitchpine to Australia and New Zealand. They are under a great disadvantage, however, in that all British vessels trading into Australian ports are subject to loadline restrictions which would considerably reduce their carrying capacity as compared with American vessels to which restrictions would not apply. The Marine Department has had the matter taken up with the Australian Government and it is expected the discrimination which exists under the present regulations will be done away with

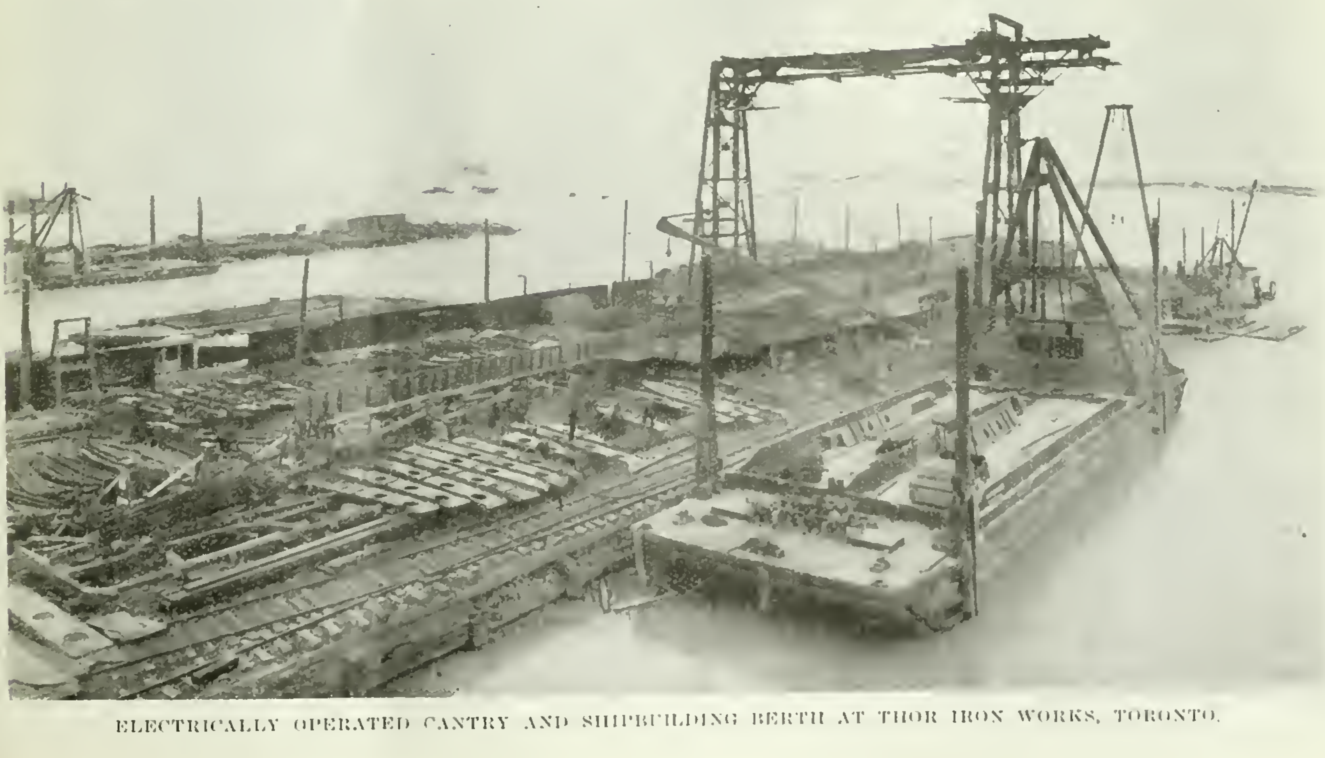
ELECTRICALLY-OPERATED GANTRY AT THOR IRON WORKS, TORONTO

AT the shipbuilding plant of the Thor Iron Works, located at the foot of Bathurst Street, Toronto, an electrically-operated gantry has recently been constructed over the shipway, which greatly facilitates the shipbuilding operations being carried on there.

The gantry, the general features of which are shown in the illustration, has a capacity of 20 tons, a span of 60 feet, and one outboard arm of 15 ft. in length. It has a clear lift of 56 ft. from hook to rail; is of double girder type construction, with operating cage suspended from trolley. The speeds and scope of service are as follows:—Hoist, 30 ft. per minute; travel, 250 ft. per min.; and traverse, 200 ft. per min. The hoist motor is of 35-h.p.; travel motor, 35-h.p.; and traverse motor, 7½ h.p., all operating on 500 volts, direct current. The gantry is fitted with electric brakes in addition to mechanically operated brakes, and all the gears are of cast steel. Electric light clusters are distributed about the gantry, so that night work can be carried out without inconvenience or delay.

In addition to a view of the gantry, the photograph shows construction progress on the first of two steel ocean-going freighters, orders for which were received a few months ago.

SOME makers of windmills estimate that a wind of 16 miles an hour may be expected for eight hours per day on the average for every day in the year. This does not mean that such a wind can be relied upon every day in the year, of course, but that the average wind all the year round would equal 16 miles an hour for eight hours every day.



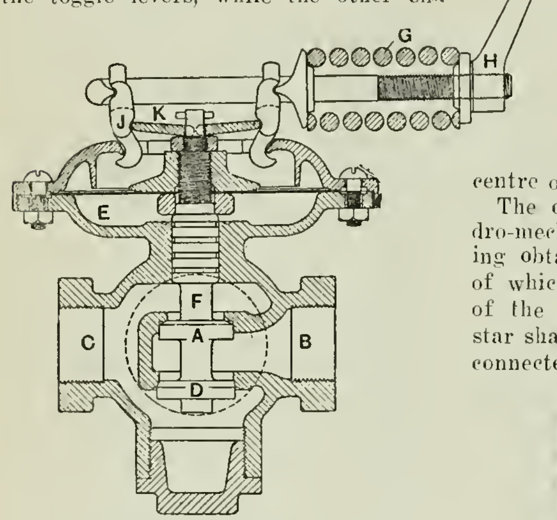
ELECTRICALLY OPERATED GANTRY AND SHIPBUILDING BERTH AT THOR IRON WORKS, TORONTO.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

PRESSURE-REDUCING VALVE

THE sectional view shows a Foster patent reducing valve embodying improvements which have for their object quieter and smoother action and more gradual and uniform passage of the fluid from the high to the low-pressure side of the valve. In the Foster reducing valve the pressure desired to be delivered to the heating or other system is set and automatically governed by an adjustable spring acting through a system of toggle levers on a diaphragm in the valve chamber. This diaphragm has a spindle passed through it; one end of the latter is engaged by the toggle levers, while the other end



PRESSURE REDUCING VALVE.

carries a double-beat valve having two seatings in the valve body through which steam or any fluid under pressure is passed. The invention consists essentially in forming one of the double-beat valves as a sliding piston valve, whilst the other valve of the pair is of the usual bevel-edged type.

Referring to the illustration, B designates the inlet and C the outlet of the valve, E the diaphragm, F the valve stem, A D the double-beat valves, G the adjustable spring, H a nut on the screwed portion of the pring rod for regulating the delivery pressure, and J toggle levers acting in combination with links K. The valve A of the double-heat valves is made in the form of a sliding piston valve as shown, while the other valve D of the pair is of the usual bevel-edged lift type, by which means high-pressure steam is enabled to pass first through the lift valve D whilst the piston valve A remains closed until the delivery pressure is reduced to such a point that the piston valve A is also opened and the steam or fluid passes through both the double-beat valves in a greater volume. It is claimed that "wire drawing" or cutting action on the valve face and seats is thereby prevented. Sir W. H. Bailey & Co., Salford, England, are makers of the foregoing apparatus.

HYDRAULIC SHRINKER FOR AUTOMOBILE RIMS

A COMBINED hydraulic and mechanical shrinking press for the exact sizing of rims for automobile wheels has been built by the Metalwood Mfg. Co., Detroit, Mich. The accompanying engraving shows the mechanism, which is practically all on the rear side of the main frame, the front or operating side simply having a circular opening surrounding the eight pressure dies which operate radially toward the centre of the main frame.

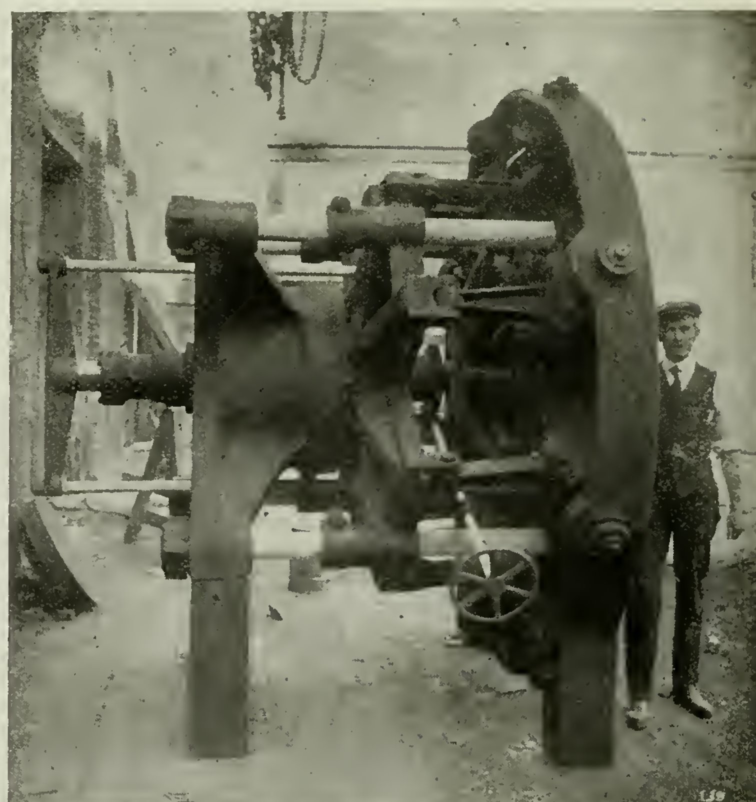
The operation of the machine is hydro-mechanical, the prime movement being obtained from a ram, the cylinder of which is supported on the rear legs of the machine. The crosshead is of star shape, each of the eight arms being connected by a compression link to the several toggle joints located around the outer edge of the main frame.

The closure of the dies is regulated by the handwheel in the foreground of the picture, which by means of worm gearing causes a nut to advance or recede on the end of the ram, the nut making stop contact with the main frame and regulating the stroke of the ram accordingly. The weight of the crosshead and ram is carried on the horizontal tension members, suitable babbitt-lined bosses being provided for this purpose.

The ram is of hard semi-steel, finely polished and packed by a receding nut, U-type chrome leather packing being fitted to both the main ram and the ram in the pull-back cylinder. The machine is designed to operate at pressures between 1,000 and 2,000 lbs. per sq. in. developing 675 tons total pressure on the dies with the former pressure. Steel castings are used freely, and carbon steel for the dies.

HEAVY TURRET LATHE

FOR some time the Corbet Foundry & Machine Co., Owen Sound, Ont., have been building heavy turret lathes espe-



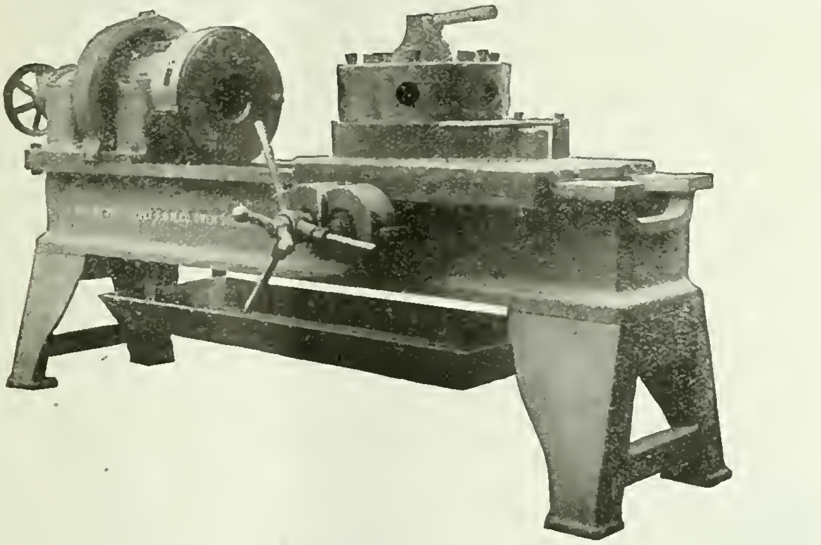
HYDRAULIC TOGGLE PRESS FOR SHRINKING RIMS OF AUTOMOBILE WHEELS.

cially suited for munition work, and their latest design, based on extensive experience is shown in the accompanying illustration. Exceptionally heavy proportions have been adopted throughout, the driving pulley being 14 in. dia. x 8 in. face with main gears of 7 to 1 ratio.

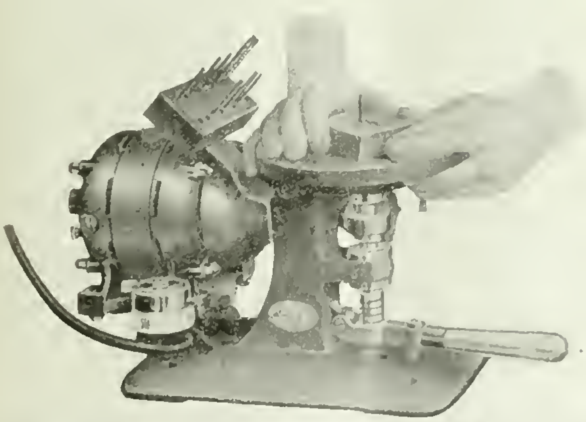
The hollow spindle is made to accommodate shell forgings of 6 in. size and under, the main bearing being sufficiently large to dispense with outer steady bearing. Machine cut steel gears are used throughout. An automatic chuck operated by hand wheel at end of headstock provides ample gripping power.

Turret proportions are very liberal and feed is obtained from a belt-driven worm shaft at the back of the bed, meshing with a worm wheel on the outer end of the feed pinion shaft. Handfeed is provided through a three spoke spider with clutch gear.

These machines are equipped complete with chuck, countershaft, and controlling clutch, the net weight of the lathe being 5,200 lbs.



HEAVY TURRET LATHE FOR MUNITIONS PRODUCTION.



GEAR DRIVEN DIE-FORMING MACHINE WITH HELICAL CUTTERS MAKING CONTINUOUS CUT ON WORK.

DIE FORMING MACHINE WITH HELICAL CUTTERS

THE machine illustrated herewith is designed specially for finishing blanking dies and similar work, after the core or surplus stock has been drilled out and removed, and is operated by a motor which can be used on an ordinary lighting circuit.

The chief feature about the machine is the employment of cutters having a multiple thread helix, the section of the thread being that of a ratchet or buttress screw, which, when rotated at high speed, shears the material off the work. With the pitch of the cutting threads in the proper direction, the work is drawn down and made to hug the platen or table assisting greatly in controlling the work in hand. This action also carries the chips down so as to have the line marked out on the blank visible at all times.

The machine consists of a main frame carrying the vertical cutter spindle, the driving shaft being disposed at right angles to the main spindle which it drives through spiral gearing. The motor is especially wound to take care of the intermittent loads and is completely protected from injury by chips or dust.

The work table is adjustable, and is set at right angles to the spindle, the desired amount of clearance being obtained through the use of tapered cutters, which with a level table give uniform clearance on all sides of the die no matter from what direction the work is applied to the cutter. One benefit of this feature is that when grinding dies in use, the opening is enlarged uniformly without distortion due to unequal clearance angles.

All the cutters have plain shanks $\frac{1}{4}$ in. dia. and are made straight, tapered, and reverse taper, from $\frac{1}{8}$ in. to 5-16 in. diameter. They are held in a drawdown collet which is closed by a spring at the lower end of main spindle, and require no feed screws, slides or vises in which to hold or control the work in operation.

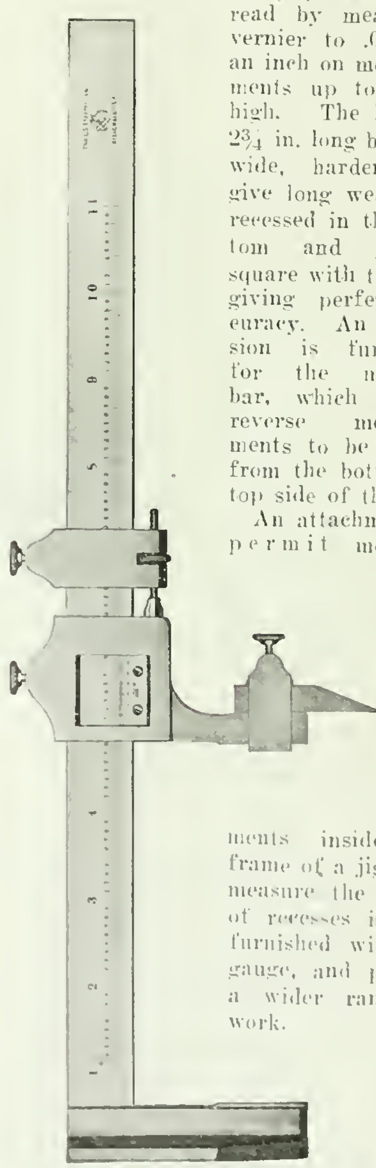
The machine is the product of the Anderson Die Machine Co., Bridgeport, Conn., and is distributed by R. E. T. Pringle Co., Toronto, being regularly equipped with motor for any desired voltage, cord and plug, tool rack and twelve selected cutters. Weight with motor 55 lbs.

NEW VERNIER HEIGHT GAUGE

A NEW vernier height gauge, having improved attachments for greater efficiency, has been brought out by the L. S. Starrett Co., of Athol, Mass. Toolmakers and machinists who are familiar with the Starrett vernier caliper will find the new tool of similar quality.

The bar is 10 in. long, graduated to read by means of vernier to .001 of an inch on measurements up to 8 in. high. The base is $2\frac{3}{4}$ in. long by 1 in. wide, hardened to give long wear and recessed in the bottom and ground square with the bar, giving perfect accuracy. An extension is furnished for the movable bar, which allows reverse measurements to be taken from the bottom or top side of the jaw.

An attachment to permit measurements inside the frame of a jig or to measure the depth of recesses is also furnished with the gauge, and permits a wider range of work.



VERNIER HEIGHT GAUGE WITH ATTACHMENT.

MINING IN ALBERTA DURING 1916

COMPLETE mining statistics for the Province of Alberta for the year 1916 are not yet complete and will not be available before the end of February.

The total output for the year will, it is estimated, be between 4,250,000 and 4,500,000 tons. This shows an increase of approximately 1,000,000 tons over the output for the year 1915. A much larger amount of coal is being shipped from Alberta into the Province of Manitoba than formerly. During the first three months of last year, the mines, particularly in the lignite field worked more steadily than is usual at that time of year owing to the extreme cold weather experienced. During these months, however, the output in the Drumheller district was seriously handicapped by a scarcity of railway cars. The output has also been interfered with to a certain extent by a shortage of labor, although during the last few months this has materially improved.

From January first to December fifteenth, 44 new mines were opened and 52 abandoned in the province, the number at present in operation being 248. During the same period, 18 fatal accidents occurred as compared with 18 for the whole of the year 1915, also 76 non-fatal, as compared with 66 non-fatal accidents during the year 1915.

A mine rescue car has been installed in the Drumheller field during the year, there being now three mine rescue cars in operation as follows:—One in the Crow's Nest Pass, one in the Canmore and Bankhead district and one in the Drumheller district; there are also five mine rescue stations placed as follows: Three in the Lethbridge district, one in the Brazeau, and one in the Jasper Park district. The superintendent of each of these stations devotes a considerable portion of his time to instruction in first aid work.

On July 1, 1916, competitions in mine rescue and first aid work were held at Coleman. Thirty-two certificates of competency in mine rescue work were granted during the year, making a total of 261 certificates issued since the establishment of mine rescue stations in the province. Provision has also been made for the payment of men doing mine rescue training at the rate of 50 cents per hour. Two teams are kept at each mine, each team being expected to undergo at least one training each month. A large number of mines in the province are adopting the use of electric cap lamps with very satisfactory results. A number of electrical coal cutting machines have been installed in different mines during the year.

Seven of the new mines which were opened during the year are located in the Grade Prairie district about 400 miles northwest of Edmonton and are supplying coal to the settlers there. During the year two copper mines were opened west of Banff, on the main line of the Canadian Pacific Railway. These mines are situated near Eldon. Only a small amount of development work was done, however, and they are now abandoned. On the property owned by the Alberta Copper Co., there is a vein between 5 and 6 ft. in thickness, on which a tunnel is being driven for a distance of 154 feet, and on the property owned by the Calgary Copper Co., there is a vein 12 ft. in thickness.

NOVA SCOTIA STEEL & COAL CO.

A MEETING of the directors of the Nova Scotia Steel & Coal Co. was held at New Glasgow, N.S., on January 9. Those present were: G. S. Campbell and J. Walter Allison, of Halifax; W. H. Chase, Wolfville; Lorne C. Webster, Montreal; R. E. Chambers, New Glasgow; W. D. Ross, Toronto, vice-president; and Col. Cantley, New Glasgow, president.

It was shown that the output of the New Glasgow plant for the calendar year ended December 31 last, was more than 60 per cent. greater than that of 1915, while the orders on hand are sufficient to keep the plant fully occupied for a large portion of the current year, even at the increased rate of production prevailing in 1916.

It was also shown that their subsidiary, the Eastern Car Co., had received a further order for three thousand cars for Europe. These cars are to be delivered at a Canadian port, and, with other orders now on hand, will be sufficient to keep the car plant fully occupied for the whole of 1917.

PEACE PROPOSALS—FROM "HUMOR IN THE ROYAL NAVY."

CANADIAN REVENUE FOR NINE MONTHS

THE financial statement of Canada for the nine months of the fiscal year ended with December shows a total revenue of $166,856,349, as compared with $122,027,821 in the corresponding period. In the month of December alone the revenue amounted to $21,943,775 an increase of over four millions.

Expenditures on the war in the nine months aggregated $170,229,748, a growth of eighty-five millions. In the same period domestic expenditures on consolidated account totalled $81,690,505, an increase of seven millions. On the present basis of capital and consolidated outlay compared with the revenues there will be a surplus, apart from the war expenditure, of about sixty millions.

The Customs Department is the principal contributor to the aggregate revenue, furnishing $97,332,210 in the nine months, which is an augmentation of $28,000,000. Excise brought in eighteen millions, public works almost twenty millions, and post-office twenty millions. At the end of December the net debt, increased by interest charges, stood at $722,111,449, a growth of about $200,000,000 in the year.

COMPANIES ACT INCORPORATED

The number of companies incorporated under the Companies Act, Canada during the fiscal year ending March 31, 1916, was 534, with a total capitalization of $157,342,800, and the number of existing companies to which Supplementary Letters Patent were issued was 71, of which 28 increased their capital stock $68,996,000, and 11 decreased same $4,811,700. The remaining 32 were granted Supplementary Letters Patent for various objects, such as changing names, extending powers, etc., making a total of 605 charters and supplementaries issued during the year, an increase of 59 as compared with the previous year. The total capitalization of new companies and the increased capital of existing companies amounted to $221,527,100.

The Reason Why.—An English militant crusader strolled into a barn where a young man was milking a cow. With a snort, she asked: "How is it that you are not at the front, young man?"

"Because, ma'am," answered the milker, "there ain't no milk at that end."

Vol. XVII. JANUARY 18, 1917 No 3.

A GLIMPSE OF POST-WAR TRADE EFFORT

THE cancellation of Allied munitions orders in the United States, and the aggressive bidding of Hadfields Ltd., Sheffield, England, for American naval shell contracts should not pass without the careful consideration of every Canadian manufacturer, and particularly those who have received the benefit of orders which have been directly or indirectly the result of war conditions. In the first place the cancellation of British shell orders in the United States is an indication of the manner in which production has been increased in Great Britain, and what is true of finished shell output is equally so of the principal raw material—steel, entering therein. It may therefore be anticipated that contracts for the latter will show an accelerating tendency to shrink at an early date, if the process be not already operative.

In the second place the low bid of British makers on American shells illustrates emphatically that the cost of British and European production is on a much lower level than in the United States. Further, the great disparity between the delivery dates of Hadfields and their nearest domestic competitor seem to indisputably indicate greater efficiency, both as regards operative skill, and production equipment installed. Aside, however, from the special circumstances responsible for this glimpse into the future, putting two and two together is not much more simple than reaching the conclusion that happenings such as this have a bearing upon the industrial developments which may be expected to follow the war.

The manufacturer on this side of the Atlantic needs only ordinary foresight to see that the time is coming when there will be no more munition orders placed at prices made reckless by necessity, nor will there be a demand for other manufactures and natural products, meantime factors in the great military campaign at valuations which have upset normal standards. The end of the war will bring this change—if it does not come before, and in that same time there will be released for the manufacture of normal products all the vast and efficient machine which has been devoted to the taskmaster Mars since August, 1914. On what basis then will we be able to meet industrial Europe after the war?

The outlook is that the competition of old world manufacturers will be much keener than the past has ever known. In Canada and the United States' price-no-object war buying, with general prosperity and high wages have put the cost of production on a much higher level than has ever been known. On the other hand in the Old World where the machinery of production has been greatly developed, immense armies will return to the usual walks of life, and labor will undoubtedly be plentiful and probably cheap. Costly production then in this country and cheap production in Britain and Europe can only lead to competition from across the seas, which will either result in a reduction of prices on this side or the purchase of foreign goods. Tariff adjustments may be made which will help the situation, but even so Canadian manufacturers would do well to mark the significance of such incidents as Hadfields' bidding on American shell contracts. For the benefit of our readers who may not have had the opportunity of perusing the details of the United States Navy Department armor piercing shell bids referred to, a brief comparative statement follows:

Hadfield's made bid for the delivery of 3,000 16-inch shells in sixteen months, at $513 each. The next lowest bid was that of the Crucible Steel Co., which agreed to make 1,700 of these shells in twenty-six months at $768 each. The highest American bid, that of the Midvale Steel Co., was $900 each for 1,000 shells, to be delivered in twenty-four months.

The British company's bid was $356 each for 4,500 of the 14-inch projectiles, to be delivered in eleven months. The next lowest bid, that of the Washington Steel & Ordnance Co., was $500 each for 1,000 shells, to be delivered in twenty-two months. The Midvale Co. offered to make 5,600 of these shells in thirty months at $550 each. The only other bid on 14-inch shells was that of the Crucible Steel Co., which offered to make 2,000 of them in forty-two months at $543 each.

THE MUNITIONS LABOR SITUATION

CONSIDERABLE irritation is manifest as a result of the official campaign to stimulate recruiting for munitions production in our metal-working plants. Indefiniteness as to the class of labor wanted seems to be the "lost chord" in the various clarion calls issued to date, and while this in itself might have been foreseen and therefore avoided, it may be taken for granted, with the various individual experiences brought so very forcibly to their notice, that the Imperial Munitions Board, through its Department of Labor, will lose no time in switching its campaign effort to meet effectively its own insistent need and the offerings as well of those willing to meet same.

The undertaking to man our munitions plants to the limit of their capacity with either available male or female labor verges on the stupendous, besides being beset with difficulties apt to be overlooked, and perhaps minimized to the vanishing point even when known. Transportation troubles in the matter of fuel, steel, forgings, etc., have militated materially in recent weeks against the employment of the full quota of labor in many plants, and it may not be assuming too much to infer that the cases of individual inconvenience recorded have had the foregoing more than the Labor Department of the Imperial Munitions Board, to blame for the circumstances in which they found themselves. Now that our passenger train service has been materially restricted, and the locomotives and train crews have been transferred to supplement freight haulage and eliminate the congestion bogey, we may expect to see the scope of employment on munitions work of every description enlarged and complaints of disappointment by those willing to serve get beyond the range of possibility.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., Jan. 15, 1917.—The industrial and commercial world is still much in doubt as to the underlying purposes of recent efforts towards the opening of peace negotiations. This condition of affairs is being reflected in general trade circles, and advance contracts for materials are showing a decrease. Considerable relief in freight congestion is looked for as a result of the reduction in passenger schedules by Canadian railroads.

Pig Iron

Some anxiety has been experienced as a result of recent political events but capacity production is still the order at most furnaces, although difficulty is being experienced in the receipt of raw materials owing to transportation facilities, etc. Some relief has been shown in the coke situation, spot furnace having fallen to $9 per ton; prompt foundry shows a decline of $1 per ton the current quotation being $11 per ton. Canadian pig quotations are practically withdrawn, the nominal price of Victoria being $40 per ton.

Steel

The steel situation has been little affected by the political happenings referred to. While it is generally conceded that prices have attained a maximum high level, advances here and there still indicate the apparent strength of the market. Owing to existing conditions and the uncertainty of early future developments, consumers are not so keen to place orders for future requirements at the present high prices. The demand for steel plates is very great; in fact it is doubtful if ship building needs will be entirely satisfied for a considerable period after the close of hostilities. It is not improbable that higher quotations may prevail for this class of steel. An advance of $10 per ton has been placed on tank plates, Pittsburgh, the quotation being now on a basis of $5 per hundred pounds. Sheet mills are booked many months ahead, but owing to the non-delivery of sheet bars the output has been largely curtailed during the past few weeks. The quotation on blue annealed sheets shows an advance of $5 per ton, the current price being $4.75 per hundred. The situation in wire and wire products has continued very firm for some time and it is anticipated that a steady tone will prevail. The demand is very active and mills are operating at full capacity. No local changes have taken place during the week and business is generally brisk.

Metals

Unsettled conditions are still the feature of the metal situation and the general trend is toward weakness. Copper continues to become easier. Tin is uncertain but slightly higher. Spelter is quiet. Trade is steady but showing a slight undertone of weakness. Antimony and aluminum are firm and unchanged.

Copper.—Considerable activity has been shown in this metal during the past week, but the market continues unsettled owing to the uncertain conditions that still prevail. Recent developments, and their bearing on early future possibilities, have somewhat disturbed the confidence of the trade and the situation at present is one of watchful waiting. The steady decline of the past few weeks has resulted from the active selling of resale metal and the feeling that peace negotiations would materially affect the strength of the market. London quotations indicate a weaker market, and New York has also declined on lake and castings, but electrolytic has advanced ¾c, being now quoted at 29½c per lb. The situation locally continues fairly active and prices are steady and well maintained. Lake and electrolytic are quoted at 36c and castings at 35c per lb.

Tin.—This market continues to hold its firm position but owing to the unreliable nature of the information now obtainable regarding shipments, the situation is anything but settled. The strength of the markets here is largely due to the advancing London market; New York having advanced to 43c, one-half cent higher than last week. Conditions here are unchanged and prices are firm at 47c per lb.

Spelter. — The situation in spelter shows little change and still carries an air of uncertainty that characterizes conditions generally. However, the buying of spelter is relatively low to that of copper and the trade is rather optimistic regarding the early future. New York is 3/8c lower, the current quotation being 9½c per lb. Dealers here are fairly active and a slight advance is noted; the quotation this week, being 14c per lb.

Lead.—The situation in lead is firm, but an undertone of weakness is developing as a result of prevailing conditions. New York continues to quote 7½c with a declining tendency. The market here is steady with quotations unchanged at 10c per lb.

Antimony.—Little activity is shown in antimony and the market remains unchanged with prices firm at 15c per lb.

Aluminum.—The market is unchanged and quotations are steady at 70c per lb.

Machine Tools and Supplies

Trade in machine tools is satisfactory, but no pronounced activity is evident. This may be accounted for by the uncertainty that prevails throughout trade and political circles respecting early future conditions. The prospect of additional munitions contracts being placed, when a definite understanding has been reached, may enlarge the requirements of shell makers in respect to additional equipment. An interesting feature that may ultimately result in machine tool activity is the fact of many U.S. firms establishing branches in Canada. While the principal undertaking at present is along munition lines, the possibilities of domestic expansion are very encouraging.

Scrap

Activity in scrap seems to have simmered down to the purchase of actual current requirements and a general depression in prices appears to feature a rather dull situation. New York quotations would seem to indicate a general weakness, but dealers here are optimistic regarding the near future. While the present tendency is for easier prices, those effected this week are confined to scrap brass and zinc. Brass clippings are ½c lower at 16½; turnings at 15c show a decline of ¼c. Scrap zinc at 7½ is ½c lower than last week.

Toronto, Ont., Jan. 16.—Industrial activity continues to be largely centered on the production of munitions, the development taking place in this industry being quite remarkable. Coincident with this is a national call for economy in expenditure and increased production arising out of military necessities. The freight situation has not as yet improved, but the new regulations are now in effect, and the congestion in the railway yards will no doubt be relieved to some extent. There is still a shortage of coal and coke, but some relief is expected shortly, although it is doubtful if the situation will be normal until the spring.

Steel

Renewed activity is developing in the iron and steel trade, and the market appears to have lost little of its previous strength. The upward movement in prices continues, and the situation is tighter than ever before, due to the enormous demand of steel for munitions. On this account it is becoming very difficult to get merchant bars and other steel products, with the result that prices are advancing. A large tonnage of steel will have to be imported from the United States, as the domestic mills cannot meet the extraordinary demand. Prices of iron and steel bars are still withdrawn, and those given in the selected market quotations are, in the meantime, entirely nominal. When new prices are issued they will most probably be around $4.05 to $4.10 per 100 lbs. Quotations on such products as plates, tubes and sheets are very firm on account of the situation in the U. S. Higher prices on plates are predicted, due to the continued demand from shipyards and car builders. Plate mills are filled for months ahead, and deliveries consequently are very slow. Prices on locomotive and merchant tubes are largely nominal, as the mills are filled up on both grades for from six to nine months. Prices on wrought pipe are very firm, and a further advance is likely at no distant date. The demand for wire rods is as insistent as ever, and prices are steadily advancing. It is understood that inquiries for 10,000 tons of wire rods have recently been sent to the States by Canadian interests.

The market for black sheets continues very firm, due to the situation in the U. S. The output of sheets is being restricted on account of unsatisfactory deliveries of sheet bars. The output of the mills is largely sold through the first, and partly through the second quarter. Prices of galvanized sheets are also firm, but unchanged.

Pig Iron

The situation in the pig iron market is anything but satisfactory. There has been for some time a considerable falling off in the production of foundry iron owing to the insistent demand for basic pig for steel making. To make matters worse a serious shortage of coke has developed, and some foundries have been obliged to close down temporarily. The coke situation is acute, and there is little prospect of immediate relief. Prices of domestic pig irons are still withdrawn. The Buffalo market is a little more active and prices of foundry irons remain firm at $35 at furnace.

Scrap

The market for scrap ingot metals is now steadier after the recent decline, but has still a weak tendency. Indications do not point to a revival in the near future, and a further decline in price is not unlikely. Prices of scrap steel, on the other hand, are holding firm, but no changes have been made during the week. The embargo on the export of steel scrap is tending to depress the market, particularly on steel turnings, as supplies of this material are again accumulating.

Machine Tools

Business has been rather slow during the week compared with the latter part of last year. Prospects, however, are favorable, and a resumption of activity is looked for any time. The building of new munitions plants and extensions to others is bound to have a beneficial effect on the machine tool trade and result in considerable business.

Supplies

Higher prices continue to feature the market for machine shop supplies, due to the high cost of raw materials. The more important lines which have advanced are as follows:—Armstrong tool holders, list plus 40 per cent.; Armstrong ratchets, plus 20 per cent.; Weston ratchets, net list; quick drill vises, plus 20 per cent.; drop forged lathe dogs, plus 15 per cent.; "C" clamps, plus 15 per cent. Drop forged wrenches are 25 per cent. off list. Chucks are unchanged at list, plus 30 per cent., and carbon steel cutters list, plus 40 per cent. An advance has been made on carbon drills, while high speed drills are double list, plus 35 per cent. A new discount of 27½ per cent. has been issued on tinners' rivets, as against 30 per cent. formerly. Leather belting is higher, the new discount on extra heavy being 30 and 5 per cent., but standard is unchanged at 40 per cent. Leather lacing is now $1.50, and leather insides $1.30. Gasoline and benzine have advanced 1c per gallon, and are now quoted at 28½c and 27½c per gallon respectively.

Metals

The situation in the metal markets is practically unchanged, and there have been no developments of importance during the week. The peace proposals are still affecting the market to some extent and will doubtless tend to steady prices for a considerable time. Prices generally are firm and unchanged.

Copper.—The market is steady and prices firm. Practically all the big producers are sold up for six months, and are out of the market. Prices being quoted now are for resale metal. Local quotations are nominal and unchanged at 36c per pound.

Tin.—Quotations in London advanced recently, but the New York market is dull and unsettled, with a small volume of business. Local quotations unchanged at 47c a pound.

Spelter.—The possibility of the war being prolonged has strengthened the spelter market, but prices are unchanged. Local quotation, 13½c per pound.

Lead.—The market is dull and featureless at unchanged quotations. Local price, 9½c per pound.

Antimony.—The market continues dull and prices have an easier tendency. Local quotation, 18c per pound.

Aluminum.—The market is quiet and easy, with quotations unchanged at 68c per pound.

No. 4. Inclinable Open Back Press.

Consolidated Presses

represent the highest grade in quality of material, design and workmanship, and have many exclusive features which make for economy in operation, notably the three locking points in the hubs of all flywheels, giving 20 per cent. more production than any press having only two locking points in flywheel to engage clutch.

PRESSES FOR MARKING FUSES, FOR FUSE BODIES, FOR BLANKING, CUPPING AND DRAWING CARTRIDGE CASES.

Also a general line of Punch and Inclinable Presses.

Manufactured by

The Consolidated Press Co.
HASTINGS, MICH.

Get our beautifully illustrated catalog for all the fine points of "consolidated" construction.

Nos. 0, 2½, 3 and 4 carried in stock at Toronto.

The A. R. Williams Machinery Co., Limited

TORONTO, ONTARIO

You Can Depend Upon Geometrics

They are used on every make of Screw Machine—with absolute satisfaction, too.

The majority of Screw Machine users know this. Do you?

Geometric Die Heads are arranged for cutting any diameter, pitch and form of thread. Right or left-hand. Flush to shoulder, where necessary. A micrometer adjustment makes possible quick and accurate variations for a tight or loose-fitting screw. The chasers open automatically, so that no backing-off occurs to injure the thread. Length of thread accurately governed—short or long.

When you are ready, let us aid you. Our publication, THREADS, will help us get acquainted. It is free. May we have your address for our mailing list?

THE GEOMETRIC TOOL COMPANY

NEW HAVEN, CONN., U.S.A.

Canadian Agents:—WILLIAMS & WILSON, LTD., MONTREAL. THE A. R. WILLIAMS MACHINERY CO., LTD., TORONTO, WINNIPEG AND ST. JOHN, N.B.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Ottawa, Ont.—The Ottawa Car Co. is building a plant at a cost of $40,000.

Wingham, Ont.—The Western Foundry Co. contemplate an addition to their foundry here.

Hepworth, Ont.—The Hepworth Light & Power Co. propose building a power plant near here.

Toronto, Ont.—The Consolidated Steel Co. will build an addition to their plant at 1154 Dundas street.

Montreal, Que.—The Canada Stove & Foundry Co. contemplate building an extension to their plant at St. Laurent, near here.

Vancouver, B.C.—The Pacific Great Eastern Railway Co. will commence work soon on a machine shop at Squamish, B.C., to cost $15,000.

Toronto, Ont.—The Chapman Double Ball Bearing Co., of Canada, have been granted a permit to erect a $25,000 two-storey brick addition to their factory on Sorauren avenue.

Toronto, Ont.—The Turnbull Elevator Co., John street, have purchased a factory site at the corner of Bloor and Lansdowne, consisting of about 4¼ acres. The price paid for the property is $106-000.

Orillia, Ont.—A new company known as Electro-Foundries, Ltd., has been formed to take over the smelter and install an electric furnace. Capitalists connected with the International Molybdenum Co. are interested in the new venture.

Montreal, Que.—The Howard Smith Paper Mills Co. will shortly take over the recently purchased Crabtree mill. Plans are being completed for the necessary alterations which will change it from a newsprint to a bond paper mill. The mill will be considerably enlarged, one of the additions consisting of a heater room 125 ft. by 60 ft.

London, Ont.—Beatty Bros., of Fergus, will establish a foundry at Chelsea Green, along the London & Port Stanley Railway tracks. The building to be erected will cost $28,000 or $30,000. The company will manufacture iron pumps, barrel churns, grain grinders and hand and power washing machines. Beatty Bros. have hitherto bought their castings.

Kingston, Ont.—The Kingston Smelting Co., will shortly be running to capacity. The lead that will be smelted in this plant is to be obtained from British Columbia, the United States, and also from mines in this district. At the present time there is an embargo on crude lead from the United States, but the management hopes to have this removed.

Steel Plant for Toronto.—The Toronto Harbor Commissioners have completed arrangements with the Imperial Munitions Board, through the chairman, J. W. Flavelle and Col. Carnegie, whereby the Munitions Board will have erected for them an electric steel and forging plant with an initial capacity of 300 tons per day. Ten six-ton, three-phase 25-cycle Heroult type electric furnaces will be installed.

MUNICIPAL

Cayuga, Ont.—The Town Council propose purchasing gas engines and pumps for a waterworks system.

Brantford, Ont.—The City Council are considering the question of developing hydro power on the Grand River.

Oakville, Ont.—Voting on the by-law to grant certain minor concessions to the Acme Tire & Rubber Co. will take place on Monday, January 22. The company propose establishing a factory here for making rubber tires, etc.

Toronto.—The York Township Council has passed a by-law granting a fixed assessment for the next twenty years to the Canada Cycle & Motor Car Co., with allied businesses under such names as the Russell Motor Car Co., or the Canada Cycle & Motor Car Co. The company are building a factory at Weston.

Toronto, Ont.—A new activated sludge unit is to be given a trial at the Morley Avenue sewage disposal plant. Should it prove successful in preventing odor from spreading, Works Commissioner Harris will recommend that the activated sludge system be adopted for the entire plant. An appropriation for the trial unit will be placed in the estimates of the Works Department.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

TENDERS

St. Lambert, Que.—Tenders will be received up to January 22, for the supply of a horizontal shaft centrifugal pump, electric motor and switchboard. Specifications may be obtained from H. A. Gibeau, town engineer, Town Hall, St. Lambert, Chambly Co., P.Q.

Winnipeg, Man.—Tenders will be called until February 12, 1917, for works required for the completion of the new Parliament Buildings, which include the following: Heating and ventilating, electric conduit and wiring. Thos. H. Johnson, Minister of Public Works, Winnipeg.

London, Ont.—Tenders will be received up to Monday, Jan 29, 1917, for the supply and delivery of: (a) Special railroad track work consisting of five (5) whole and two half crossings of manganese steel construction; (b) Two horse-drawn road oil distributers. Specifications, form of tender, etc., can be seen at the office of H. A. Brazier, city engineer.

Winnipeg, Man.—Tenders addressed to the undersigned will be received up to Monday, February 5, 1917, for the supply of indicating and recording apparatus for two Venturi meters. Specifications and form of tender may be obtained and form of contract may be inspected at the offices of the district. R. D. Waugh, Chairman of Commissioners, 501 Tribune Building, Winnipeg, Man.

GENERAL

Toronto, Ont.—The D. Harris & Co. glue factory may be removed to Ashbridge's Bay. Officials after visiting reduction plants in the United States, found that such a plant by means of proper water cooling devices can be operated without giving forth obnoxious odors.

MARINE

Victoria, B.C.—The auxiliary schooner Margaret Haney, which is being built by the Cameron Genoa Mills Shipbuilders, Ltd., will be launched about the end of January. The 160 h.p. Bollinder engines will be installed after the vessel has been launched.

Yacht "Florence" Sold.—The steam yacht Florence, formerly owned by Sir John Eaton, of Toronto, and since the war began in the service of the Canadian Government as a patrol and scout vessel, has been sold to the French Trading Co., of Martinique, F.W.I. It is understood she will be used by her present owners for commercial purposes. She has left for Fort de France, Martinique.

Shipbuilding Bounties.—From a note in a recent issue of the *Board of Trade*

Journal, we gather that a new Shipbuilding Act for Newfoundland provides for payments to be made to shipbuilding concerns situated in the colony. These payments take the form of making up the net annual profits of 7 per cent. for a term of 15 years should they be below this figure. The Act also provides for free importation of materials for the equipment of shipyards as well as of those used in shipbuilding. Furthermore, the tonnage bounties under the Act of 1908 are to be doubled.

PERSONAL

W. S. Atwood, chief engineer of the Canadian Car & Foundry Co., Montreal, has been appointed operating manager.

Lieut.-Col. L. T. Martin, of O'Brien & Martin, railway contractors, Montreal, has been requested to raise a construction battalion for service in France.

A. G. Pounsford, until recently safety engineer of the Pulp and Paper Manufacturers' Safety Association, has been appointed general manager of the Port Arthur Pulp & Paper Co., with head office in Toronto.

Capt. K. T. P. Woods, who spent many years at sea in the Monarch Line, out of Glasgow, Scotland, and for the past three years has been an officer on the cable ship, Restorer, has been appointed shore captain at Vancouver, B.C., for the Pacific Steamship Co.

E. P. Mathewson, of Montreal, was awarded the coveted gold medal of the Metallurgical Society of America for his achievements in metallurgy during the past year, when the annual meeting of America's leading mining organization convened in Montreal recently. The medal is awarded annually to the member performing the most valuable service in the interest of the development of American mineral resources.

BUILDINGS

Toronto, Ont.—The Campbell Flour Mills have been granted a permit to erect a bridge between their mill and warehouse at Monarch road, to cost $850.

Hamilton, Ont.—The Canadian Westinghouse Co. propose erecting an office building.

RAILWAYS AND BRIDGES

St. John, N.B.—It is reported that the Dominion Government has acquired the International Railway, which runs from Campbellton, N.B., to St. Leonards and the Maine border. It hints at the purchase price being between two and three million dollars.

WOODWORKING

North Vancouver, B.C.—Fire recently damaged the North Vancouver Sash & Door Co.'s factory to the extent of $3,500, which is partly covered by insurance.

TRADE GOSSIP

A. O. Leslie & Co., Montreal announce the completion of 50 years in business. Present officers of the company are as follows: President, William S. Leslie; vice-president, Thomas H. Jordan; director and secretary Edward H. Copland.

The Canadian SKF Co. has opened an office at 47 King Street West, Toronto, where a complete stock of ball bearings will be carried. The Canadian Fairbanks Morse Co., will continue as sales agents for transmission equipment made by the parent concern at Hartford, Conn.

The Albany Pump Co. has equipped a plant at 16 Pearl street, Toronto, for making the "Albany" rotary pump and munitions gauges. A. W. Bennet, who is proprietor and manager of the concern, formerly carried on business at 206 King street west, Toronto, as Canadian agent for the "Albany" pump.

The Clark Equipment Co., Buchanan, Mich., has taken over the business of the Celfor Tool Co. and the Buchanan Electric Steel Co. The new company has been organized for the above purpose and the merger is solely for the purpose of strengthening both concerns. There will be no change in either the manufacturing or selling methods of either company.

The Imperial Oil Co., held its annual convention at Sarnia, Ont., from Jan. 9 to Jan. 13 which was attended by about 65 managers and salesmen of the Ontario Division. The convention was president over by G. W. Mayer, managing director of the company. A number of interesting papers were read and a banquet lent additional interest to the proceedings.

Lake Lines to Raise Rates.—The International Water Lines Passenger Association, at its convention held at Quebec recently, decided to raise the passenger traffic rates on the Great Lakes, and certain rivers in the United States, as well as in Canada, but the Canada Steamship Lines, Ltd., announce they will not raise their rates on the St. Lawrence to the Saguenay River.

The George T. Ladd Co., Pittsburgh, Pa., announce that the name of what was originally the "Milne" boiler has been changed to the "Ladd" water tube boiler. The change has been made on account of improvement in design affecting the settings, feed boxes and other details to the extent that the majority of the patents which the company are utilizing have been taken out by George T. Ladd, president of the company.

Hyde & Sons Ltd., Montreal have recently added a new department to their business to include foundry supplies and equipment. The company at a late date contemplate taking up the manufacture of certain lines that are at present being imported into Canada. **Frank M. Meyers**, who has had extensive experience in foundry practice-construction and production will be in charge of the new department.

The Sterling Engine Works have taken over the plant and business of the Doty Engine Works, Winnipeg, with works and office at the foot of Water Street. While it is their intention to manufacture farm tractors as a specialty, they will also make boilers, steam and gasoline engines, iron and brass castings, cut gears, for which their plant is specially equipped, as well as general repair work. The president of the new company is V. C. Maddock, the secretary-treasurer F. Nilan, and W. J. Leaney is manager.

Cochrane, Ont.—Located on the Mattagami River, thirty-one miles west of here, is the site of the plant of the new Mattagami Pulp & Paper Co. This concern's operations, involving expenditures on construction amounting to $2,500,000, bring an important new industry to New Ontario. Just now the construction of pulp mills and hydraulic plant is being actively carried on with a view to having them in operation by next June. The company's Board of Directors are: Duncan Chisholm, Toronto, president; E. P. Shove, Colorado Springs, Colorado, vice-president; W. D. Ross, Toronto; N. B. MacKelvie, New York, and Lieut.-Col. D. M. Robertson, Toronto, secretary and treasurer.

Will Assist Refineries.—It is announced in Ottawa that the business of refining lead, copper and zinc is to be encouraged by the Canadian Government. Finance Minister White intimates that at the approaching session of the Dominion Parliament a Government bill will be presented providing aid by bounty or tariff for the refining of these metals. This is another step in the process of transferring from the United States to Canada the entire North American business of munition making. Canada has great supplies of the metals required for shells but up to the present most of the refining of Canadian matte — lead, copper, zinc and nickel—has been done in the United States. The Canadian munition business is growing to such a volume that the Government has decided that the whole process of producing proper metals for shells shall be carried on in Canada.

INCORPORATIONS

Samuel Osborn (Canada) Ltd., have been incorporated at Ottawa with a capital of $50,000 to manufacture and deal in steel and other metals at Montreal. Incrporators are A. E. Myles, F. J. Laverty and J. W. Blair all of Montreal.

Robert Maw & Co., have been incorporated at Ottawa with a capital of $50,000 to manufacture iron and woodworking machinery etc. Head office is at Montreal and the incorporators are T. B. Gould, C. Thomas and L. M. Smith all of Montreal.

Water Purification Ltd., has been incorporated at Ottawa with a capital of $40,000 to manufacture and deal in water purification and filtration plants at Ottawa, Ont. The incorporators are E. M. Knight, J. T. Mitchell and W. A. Wyman all of Ottawa.

Ajax Rubber Co. of Canada, Ltd., has been incorporated at Ottawa with a capital of $1,000,000 to manufacture rubber goods of all kinds. The head office is at Toronto and the incorporators are W. D. Hamilton, R. S. Gilpin and Y. F. Selby all of Toronto.

Industrial Chemicals Ltd., have been incorporated at Ottawa with a capital of $2,750,000 to manufacture chemicals, chemical compounds, dyes and dyestuffs etc., at Montreal. The incorporators are G. W. McDougall, L. Macfarlane, and W. B. Scott all of Montreal.

The Stevens-Aylsworth Co., have been incorporated at Ottawa with a capital of $10,000 to manufacture mechanical and electrical apparatus and machinery. The head office is at Toronto and the incorporators are W. Gilchrist, R. D. M. Moore and J. Stewart all of Toronto.

Lake Winnipeg Paper Co., has been incorporated at Ottawa with a capital of $5,000,000, to manufacture pulp and paper. Head office is at Ottawa and the incorporators are Duncan B. McDonell, of Winnipeg, also Edward Seybold and Angus W. Fraser of Ottawa.

The Universal Machinery Co., have been incorporated at Ottawa with capital of $200,000 to carry on the business of manufacturers of iron and woodworking machinery, steel makers, iron and brass founders etc. at Montreal. The incorporators are H. Johnson, C. R. Jones and F T., Malone.

The Collingwood Shipbuilding Co., has been incorporated at Ottawa with a capital of $2,600,000 to take over the plant and business of the Collingwood Shipbuilding Co., at Collingwood, Ont. The incorporators are R. H. Parmenter, Arthur J. Thomson and Samuel Davidson all of Toronto.

ELECTRICAL

Alton, Ont.—The Hydro-Electric bylaw was carried here on Monday.

CATALOGUES

The Vanadium-Alloys Steel Co., Pittsburgh, Pa., has for free distribution a folder descriptive of Vasco-Marvel, a semi-high-speed steel. This folder contains much information of interest, together with the high-speed steel standard classification of extras adopted July 22, 1915.

Hammers.—The United Hammer Co., Boston, Mass., have issued a bulletin describing and illustrating the "Fairbanks" hammer. The principal features are dealt with in detail, while each type is illustrated and accompanied by a table giving the capacity and principal dimensions of each size.

Kasenit, Ltd., London, England, have issued a catalogue dealing with the "Kasenit" compounds for all purposes or carbonizing, surface and tool hardening. The claims made for these compounds, the chief of these being tabulated control and accuracy of results, are dealt with at length.

Boiler Feed Pumps.—The G. H. Tod Co., Ltd., have issued a bulletin illustrating and describing the Tod-Attwood patent vertical ram boiler feed pumps. The principal features of this pump are dealt with in detail while a table is concluded giving the principal dimensions and other particulars for each size.

"Libby" Lathes in Automobile Shops, is the title of a catalogue issued by the International Machine Tool Co., Indianapolis, Ind., featuring the large number of automobile parts that can be machined on the "Libby" turret lathe. The principal matter contained in this catalogue consists of dimensioned diagrams of these parts machined in this lathe and the time taken in performing each operation.

BOOK REVIEW

The North Eastern Railway have issued from the Commercial Agents' Office at York, England, a Directory of manufacturers, wholesale importers and exporters situated on the North Eastern Railway System. The directory contains 1,300 pages arranged in two sections, "Towns under Trades," and "Trades under Towns," the latter section being the reverse of the former. This is a useful publication for Canadian firms desiring to open up business connections with concerns in the North Eastern district.

Steam Boilers and Combustion, by John Batey. 220 pages, 4⅜ in. x 7¼ in., with 18 diagrams. Published by Scott, Greenwood & Son, London, England. Price $1.25, post free. This volume is the fifteenth of the Broadway Series of Engineering Handbooks. In this book the author has striven to deal with the subject in a somewhat different manner than that usually found in works on this subject. Problems of combustion are examined and as far as possible cause is traced back from effect, the causes being referred to well known facts as a comparison. Although the application of certain principles is sometimes questioned, they are accepted as a whole. All analysis is based on recognized science and results compared with authorized deductions. The book contains an introduction and seventeen chapters, dealing successively with various subjects, such as combustion and steam production, principal constructional features of various types of steam boiler, steam boiler practice, temperature, etc. This briefly covers chapters one to twelve, inclusive. The principal subjects dealt with in the concluding chapters include lessons taught by experiment, Philadelphian exhibition lists, normal results obtained by abnormal methods, analysis of actual performance of a locomotive boiler and lastly, movement of gases through tubes. The book, while being in a measure technical, is clear and concise, and contains much valuable information on a phase of boiler operation which is frequently not given the attention that its importance merits. In addition to the diagrams, the book contains a number of tables and some useful rules and examples.

Heaton's Annual, Heaton's Agency, Toronto, price $1 net. The thirteenth edition of Heaton's Annual has just come from the press, and again we have to note improvements and refinements which have marked its progress from year to year. Heaton's Annual endures because recognized as a necessity both in the office and the home. Indeed, to financial or commercial houses in Canada or abroad and who do business with Canada, the book is indispensable, the expression, "Look it up in Heaton's," having become a habit in many households. The first part of the book contains complete official directories of the Dominion and Provincial Governments, to which is added this year a long list of titled and decorated Canadians that will be of interest to many families who have boys at the front; also postal information; a shipper's guide, giving every banking town, with banks and railway connections, population, etc.; commercial regulations and complete customs tariff revised to date. In the last half of the book we find up-to-date complete descriptions of every commercial town in Canada with hotels, industries, population and industrial opportunities, and an invaluable and complete summary of the resources of the Dominion, covering agriculture, agricultural districts, finance, fisheries, forests, fur farming, mining, sport, water powers, etc. The information is full, live, clearly arranged and concisely stated. Cross references are given throughout the text to a most valuable bibliography of Government and standard publications under the heading, "Where to Find It," so that the reader has access to complete information upon any subject in which he is interested. The handsome illustrated advertisements of the Provincial Governments and Boards of Trade are proof that the work receives official appreciation

INDEX TO ADVERTISERS

Safe Practice at Blast Furnaces and Its Development--I.

By Frederick H. Willcox

In its efforts to increase safety in the metallurgical industries, the Bureau of Mines, Washington, D.C., has been studying the causes of accidents at blast furnace plants also methods for their prevention. This article describes the known dangers and makes suggestion of means whereby the risk of accident may be lessened or, better still, wholly avoided.

IN all efforts to reduce accidents, the management should take the leading part. If officials believe that accidents can be prevented, and show a determination to prevent them, the rest of the force will reflect that attitude. Improvement in carefulness follows insistence on safety, as increase of output or reduction of costs follows insistence on efficiency, and for the same obvious reasons. In either case, the management must make special efforts to effect improvement, either by employing experts or by having the department heads make special study of safety conditions, and must supply necessary funds, for rarely or never can improvement be effected without the means to make necessary changes in plant equipment. It is true that all safeguards do not pay a direct financial return by preventing the accidents for the reduction of which they are installed. It is just as true that these same safeguards do pay when supplemented by other accident-prevention methods, because they show that the company is in earnest in its efforts to reduce accidents, by accepting the responsibility for cause entirely within its control.

FIG. 1—FOREMAN WARNING MEN AWAY FROM CYLINDER HEAD OF STEAM ENGINE

If the management gives tangible evidence of its interest in safety, and consequently has aroused the interest of the rest of the force, the foremen can do more to lessen risks and reduce accidents than any other group of men in the plant. As the foremen, in plant practice, organize the force for co-operation and efficiency in plant operation, and train themselves to observe and analyze the causes of trouble with mechanical equipment or furnace practice, so is it necessary for them to organize the force and train themselves for the best results in accident reduction. Although in blast-furnace works, defective plant arrangement or design, insufficient instructions, and lack of safeguards are sources of accidents, a considerable proportion of the accidents are, nevertheless, due to carelessness, thoughtlessness, ignorance, and clumsiness. However, men can not be expected to be always alert for obscure dangers, to adopt new practices that aim to put safety on a par with quickness or convenience, or to be thinking about not taking chances that rarely result in accident, unless their foremen exhibit as much personal interest, co-operation, and attention to details of work and equipment relating to accident prevention as they do in matters of practice.

The Foremen

To prevent all accidents about furnace plants, to eliminate them entirely, is impossible because many accidents happen by chance and are accidental in the most literal sense. To bring about a permanent reduction, however, does not require great study, analysis, or planning. The methods used to get out the tonnage, the incentives to good practice and maintenance of equipment, and the precautions against incompetence can be applied equally well to avoiding accidents from ignorance, carelessness, awkwardness, or unnecessarily hazardous conditions.

Should two or three tuyeres burst, or a blowpipe and cooler burn every day, or a certain bearing get hot every week, or an armature burn out persistently every month, or a car becomes derailed on a certain curve frequently, some one "gets busy" and finds out the trouble, whether mechanical or personal. To make a record in tonnage, it is not sufficient to go to the blowing room and "put the wind up," a get-together spirit is necessary. If a furnace has to be repaired every crew and foreman should understand and co-operate in the work. Any unusual and dangerous task is given constant personal attention. Such work is not done by making a preliminary inspection, preparing recommendations, and warning the men of the hazard; one or more foremen are on the job to have the work done safely. Past experience and common sense require this. However, the percentage of accidents from asphyxiation, break-outs, explosions, or slips is very small compared with the percentage of accidents that happen in regular daily work. Dozens of accidents are repetitions of the same circumstances, the cause, nature, and result being essentially identical.

Accident prevention should be handled in the same way as operating difficulties. If it is going to cost more to pay for accidents than to prevent them, if the prospect is that every fourth, sixth, or tenth man in the plant will lose 20 to 35 days' work every year by accident and during that time be replaced by a less skilled employee who will have to be trained and will possibly cause vexatious delays and mistakes, and if better and safer working conditions attract better men, operating methods and instructions should be applied to the safety problem. The same methods that have been developed for efficiency may be used to increase safety.

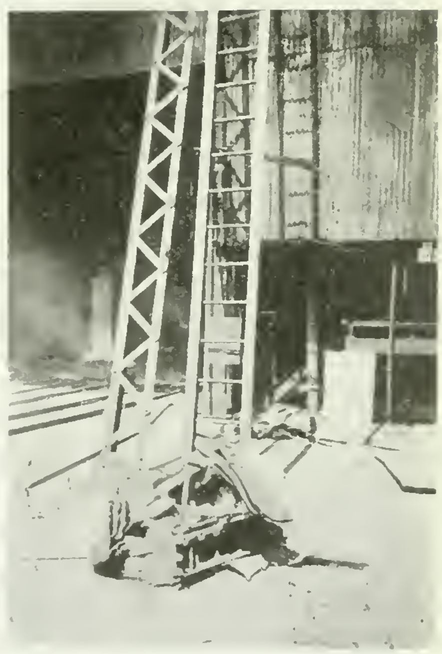

FIG. 2—SCRAP PILED AT FOOT OF LADDER

Responsibility of Safety Inspectors

Safety inspectors are invaluable for looking after recommendations, investigating accidents, pointing out possible improvements in equipment and methods, and organizing safety work, but if there is an inspector at the plant do not put the responsibility for betterment on him. His suggestions can no more eliminate accidents than suggestions can eliminate off-grade iron unless his recommendations, as well as the foremen's, are followed by improvements, detailed instructions, co-operation, and personal supervision. Moreover, if the safety inspector is not familiar with operating methods in detail, there are scores of hazardous places and practices that he will become familiar with only as accidents happen. Accident prevention is too big a job for the safety inspector unless he has the cordial co-operation of the foremen.

Plant-inspection Committee

From the sub-foremen and workmen, a plant-inspection committee of two to four men should be selected and entrusted to inspect the plant every month on a certain date, one man being replaced each month or two months, thus keeping a working nucleus of experienced men on the committee. Each sub-foreman should serve on the committee, as it may be assumed that these men have obtained promotion by displaying qualities that will be as valuable in promoting safety as in developing efficient operation. Select the workmen on the committee from those who are familiar with their work and give some promise of being permanent employees, as only a certain percentage of a plant crew can be considered a permanent asset. These men should be given opportunity to serve on the plant committee and be drawn in turn from the cast house, stock house, trestle, boiler house, and all parts of the plant.

Duties of the Committee.

The work of the inspection committee may be laid out under three heads:—

1.—Study of the accidents that have happened during the preceding month. After the committee has examined an accident report it should confer with the foreman in charge, the injured man, the man who caused the accident, any witnesses, and visit the place of the accident and see how the work is done. The comments and recommendations of the committee may be attached to the accident report for the superintendent's information.

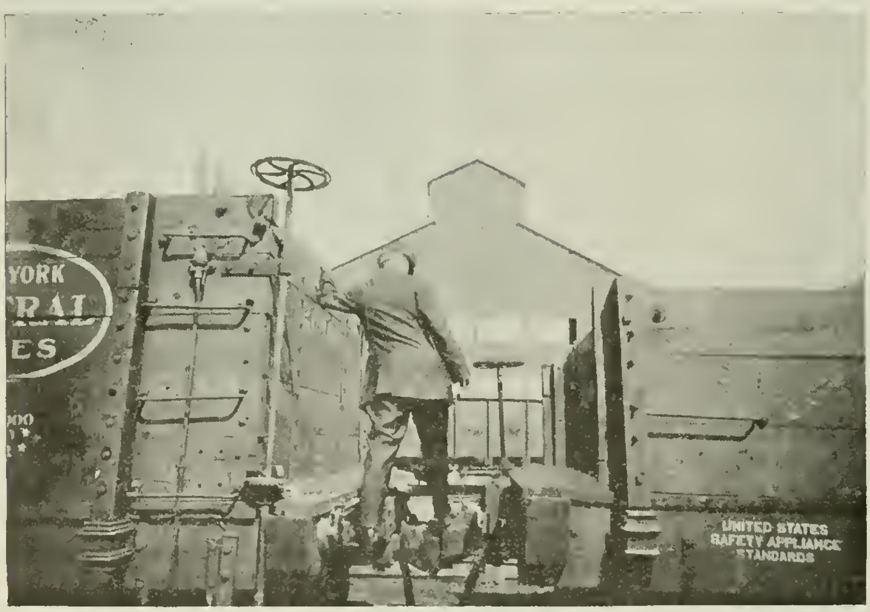

FIG. 3—A DANGEROUS PRACTICE, CLIMBING BETWEEN CARS

2.—Inspection of the plant for improper physical conditions. These conditions may include insufficient lighting, uncleanliness, refuse and debris under foot and overhead, slippery places, holes, lack of railings, overhead obstructions, poor walks, unguarded machinery, insanitation, and so on. Experience has shown that this field is the one most likely to receive attention from an inspection committee. It is unnecessary to give detailed instructions here, as in all probability 75 per cent. of the recommendations of the committee will at first concern this phase of the work.

3.—Inspection of the plant for unsafe practices. Especial emphasis should be placed on this feature of the committee's duties. Men engaged in accident prevention estimate the proportion of accidents due to the neglect of the worker at 40 to 70 per cent. Emphasize the meaning of these figures and encourage attention to this side of accident prevention. Insist that at least half of the time devoted to inspection be spent in observing operations, such as unloading or handling material, casting or pouring, method of using and condition of hand tools, condition of ladders, trestlework, and repair work. The big accident problem is unsafe practices, and these are largely a result of ignorance, carelessness, thoughtlessness, lack of instruction, lack of supervision, and mistaken eagerness or haste in accomplishing work by taking uncalled-for risks. Bettering methods of work as related to accidents is an unlimited field for the committee.

4.—First-aid instruction. Have the men on the plant committee devote as much time as is necessary to the study of first aid, such as bandaging, stretcher drill, and resuscitation methods.

Obtaining Co-operation and Recommendations

How much real interest is induced and how much good is accomplished by the above means are problems that largely solve themselves. Safety is a matter of common sense, foresight, and carefulness. Accident reduction is not insured by committees any more than larger production would be; their purpose is to arouse the interest of every man in being watchful. Men will feel an interest in a particular subject and pride in their own work if they are given responsibility and their advice accepted. Their thoroughness in inspection work and conscientiousness in reporting will largely depend on the attitude of the superintendent and foremen. If they treat the matter lightly the men will do likewise, but, if they show a desire to lessen accidents, the men will respond and will take the necessary precautions. It is hardly correct to assume that any reduction in accidents is of benefit to the workmen alone, as compensation or liability insurance are factors to be considered. Some form of appreciation of the workmen's efforts has usually been found essential and productive of results. The form which this appreciation should assume is for the management to decide. The following methods are suggested:—

FIG. 4—SAFEST WAYS OF RIDING ON RAILROAD CARS

1.—The use of a "suggestion box" in which any employee may place a signed suggestion for promoting safety. Reward the best suggestion with a substantian token such as a cash prize, watch, technical book, tool, or subscription to a trade journal. The award should be made monthly if practicable.

2.—Divide the various crews under the different foremen into divisions, and to each division that has no lost-time accidents for one to three months, or has reduced its percentage of accidents in that period, give a prize such as cigars, and award the foreman a cash bonus or a prize. In case the accident percentage rate is taken as the basis, it may be advisable to take the accumulative rate, rather than the flat rate for each distinct period. The names of those who win the awards should be posted, together with the records on which the awards were based.

Foremen's Committee

The chief foremen, such as the general foreman, master mechanic, electrician, and yard or labor foreman, and any other foremen desired, should meet with the superintendent or assistant superintendent once a month for the purpose of discussing accident prevention.

At this meeting discuss each accident that has happened during the preceding month. Find out the cause, whether negligence of employer or employee, or trade risk, and whether the accident was preventable and could have been avoided by safeguards, by instructions, by different procedure, or by more care. Use the notes of the plant-inspection committee, and if feasible have the injured man, an eye-witness, or the sub-foreman describe the accident and find out how he thinks it might have been avoided.

Should this conference with the men be made a basis of discipline, it will discourage frankness. Discipline concerns carelessness and incompetence, and this question should be decided outside of and previous to this meeting. If the accident seems to have resulted from ignorance it should be the duty of the sub-foreman to explain why the man was not instructed and to see that the men are told of this danger and of a safe way of doing the work. If the accident is due to your own oversight be frank to say so; this will not destroy discipline. If the accident is clearly due to the lack of

FIG. 5—UNSAFE WAYS OF RIDING ON RAILROAD CARS

a safeguard see that the safeguard is placed promptly, though the accident may be the first one of its kind in years.

Go over the recommendations of the plant-inspection committee, note each safety measure suggested, and put it into effect immediately or explain why it is not feasible—for instance, because it interferes with something else, must be postponed until relining, may not serve the purpose, or will cost too much. It can be accepted that many railings, toe boards, guards, steps, and signs will be

FIG. 6 SAFE AND UNSAFE SHOES

suggested, and that there will be futile recommendations. Before disapproving a committee's recommendation because of the cost, refer it to the management. It will prove worth-while to concur in many apparently trivial suggestions, to avoid discouraging the men offering them and to encourage the submission of really valuable ideas. If a different method of work is recommended, try it if it seems practicable. If it is thoroughly impracticable or useless and cannot be tried, explain why.

Putting Recommendations into Effect

After the plant-inspection committee recommendations have been accepted and approved by the foreman's committee, they should be submitted to the superintendent for approval. Approved recommendations may be put into effect in two ways. The inspection committee may locate the accident risk most thoroughly, but the design and installing of adequate mechanical safeguards is work for a skilled mechanic who has the advice of men familiar with the particular risk. To delegate the responsibility for and installation of a safeguard to a group or a committee is to make it nobody's business. Place the responsibility for this on the master mechanic.

Recommendations that deal with unsafe practices are largely made effective through education and by example. Therefore, each active or past member of the inspection committee should be made to feel that it is as much a part of his daily task to work for safety by setting a good example, giving warnings, supervising the work, and contriving how to accomplish the intent of safety recommendations, as it is to execute duties that relate solely to plant operation. It has been found feasible, assuming that these committeemen are selected by reason of their rank, experience, or intelligence, to make them gang safety leaders and to give them some little authority and responsibility in matters relating to elimination of accident risk in methods of doing work. If this is practicable locally, it is a more desirable recognition of committee service than a "safety" lapel button or watch fob, and more effective in sustaining interest. The button or fob is useful chiefly as a token of such responsibility.

Responsibility of the Foreman

The final responsibility for safety work cannot be placed on committees, gang leaders, or workmen. Practicable results in safety cannot be obtained in that way any more than a plant can be run on such a basis. To put safety work on a sound and sensible basis the foreman must give the subject serious observation, study, planning, and direction, such as is given to operating work. The safety of the workmen always has been given foremost attention by foremen, but the reduction in accidents effected by many companies indicates that this attention has been concerned more with obviously dangerous factors than with injuries due to hand labor, use of hand tools, falls, falling objects, and similar causes incident to daily work. To these causes, however, the greater part of blast-furnace accidents is due. Following are the causes of accidents at blast furnace plants, arranged in the order of their importance:

1.—Hand labor.
2.—Hand tools.
3.—Flying and falling material.
4.—Falls of person.
5.—Burns from hot metal.
6.—Machines and machinery.
7.—Cranes, hoists, and rigging.
8.—Hot water and steam.
9.—Burns from cinder.

10.—Flames.
11.—Railroads.
12.—Asphyxiation.
13.—Slips.
14.—Illness (including intoxication).
15.—Hot flue dust.
16.—Electric machinery.
17.—Explosives.
18.—Fighting and playing.

If burns from hot metal and burns from cinder were grouped together they would rank third. Hand labor and hand tools cause over 40 per cent. of all accidents; if flying and falling objects and falls of person are included, over 60 per cent. of all accidents are represented; and if burns from hot metal and cinder are added, the total represents approximately 75 per cent. of all blast-furnace accidents. This shows where the accident problem lies. Effective prevention of accident from these causes requires study, observation, experience, and instruction. No one in the plant is more capable of doing this than the foreman, no one is in such close contact with the men, and no one can combine such work with operating supervision so advantageously and effectively.

Precautions to be Observed by Foremen

The following suggestions, which cover the dangers incident to different kinds of work about the blast furnace, are not intended to serve as rules, but as useful memoranda to foremen and workmen. It is not necessary to call in the men and discuss this matter with them from beginning to end; it is even of questionable benefit to call a crew together at their place of work and repeat a long string of "don't"; precautions can better be impressed on the men gradually and at opportune times. As the precautions given in these notes gradually come to be subconsciously in the minds of both foremen and workmen at their work, to that degree will the number of accidents permanently decrease.

Avoid employing a man whose language no one of your crew can speak. Do not place a slow, heavy man where a quick, active one is required, or a slow-thinking men where a quick-witted one is required, nor keep on the same job a man who gets hurt frequently in that occupation unless the labor supply is inadequate or men cannot be shifted. When a man is employed or put to work on a new job instruct him as to his work and how to avoid accidents, warn him of unusual or obscure danger, and then put him under the charge of the gang leader or "straw boss." You should consider yourself personally responsible for accidents that happen to your men from their ignorance of danger or of safe methods. Therefore, watch for dangerous practices, ignorance, lack of skill, and carelessness, and take the necessary steps to correct faults when first noticed. Most men can be taught and encouraged to use proper methods of work, but when necessary impress on the men by admonition, warning, suspension, or discharge your attitude against carelessness or indifference. Drill your men to report immediately when injured, however slightly; send an injured man to the doctor or first-aid man, and then investigate the accident at once and discuss it with the sub-foreman and workmen in order to bring out clearly the cause and impress it on their minds.

Where it is possible, make dangerous places safe rather than attempt to guard them with signs. Where signs are necessary accept the responsibility for placing them, see that they are in good condition and that they are used. Make it your business to see that machinery, hand tools, tackle, scaffolds, or any other appliances are safe. Do not allow men to start or operate machinery unless they are so authorized. Avail yourself of all safeguards provided for the men under your direction, such as goggles, leggings, and congress shoes, when on duty about the cast house or pig machine. Exhibit carefulness in necessary personal work with machinery, electrical and steam equipment, and hand tools. Place and use prescribed safeguards or signs. In this way you will be better able to insist that the men under you observe similar precautions.

FIG. 7—SAFETY HAND LEATHER

Personally supervise any work involving unusual accident hazard, such as work in gas mains or cleaners, tearing out linings, work in the cast house and about the stoves, when blowing in or blowing out, or in event of a bad "mess" (piles of red-hot coke, slag, or iron spilled about the furnace, or in the yard, or on the tracks near the cast house), and any work about the bells or stock line. Don't allow men to go into any place dangerous from gas, falls, or falling material without breathing apparatus, safety belts and life lines, or watchers, as the nature of the work demands and circumstances permit. Never send inexperienced men to dangerous places or set them at hazardous work. Before sending or allowing men on top or where they will be exposed to material from slips, and escape is difficult, make sure that the furnace is not hanging. If the furnace is working stiff or slipping, the necessary precautions should be taken in regard to checking it or taking the wind off temporarily. Recognize that work about blast-furnace plants will still be hazardous, even after all safety measures have been taken and the force is at the "top notch" of training, skill, and carefulness. Impress this fact on the crew and insist on thorough instruction and care of every man by his gang boss.

On occasions, you will have to give detailed advice and directions to the workmen concerning dangers not here described. The more common dangers arise in work about gas-containing equipment, work about the furnace in event of a breakout, heavy scaffolding and slipping of the furnace, stopping the furnace, blowing in, loosing the water supply, and so on. Many other hazardous operations will occur to you. For such work a set of rules or notes intended for some particular plant conditions are futile or may even be dangerous unless varied to meet the situation. When unusual situations arise, safety depends on the measures taken by the foreman. Experience, coolness, and common sense are more essential than rules. Certain emergencies can be largely eliminated, however, by careful examination, forethought, and planning before undertaking dangerous work. At most plants it is the rule that, before any dangerous work is done, the superintendent and foremen together definitely determine the various steps to be taken. This should be the rule at every plant.

Following are some notes addressed to men in various occupations about the plant. Many of the men will be experienced in the different positions and know of all the principal dangers and practices mentioned. With such men all that is necessary is, when you notice them becoming careless or forgetful, to show them wherein they are becoming careless. In placing new men it is worse than useless to give them a large number of instructions as they will only be confused. Keep these notes in mind and give them general instructions and any special instruction you think they need at first. Then continue to instruct them from time to time and have the "straw boss," gang leader, or sub-foreman do the same. Personally supervise their work as much as possible, and take advantage of every opportunity to forcibly impress on their minds the advantages of safe practice. More and more, managements are valuing foremen by their care of the men as well as by their records for tonnage and cost. Keep the safety of your crew in mind always, and when you think of some new precaution in work or practice refer it to the superintendent at once and try to have it put into effect.

General Observations

If you see anyone in a dangerous place (Fig. 1), doing anything in a way liable to injure himself or others, clumsy in the use of tools, ignorant of danger, or ignoring the use of safeguards or safety rules, show him the danger and report the case if your warning is disregarded. Report at once unsafe equipment or tools, safeguards, or signs not in use or not replaced, and dangerous places unguarded. Watch other men's work for dangerous or unsafe methods, but be careful that your own work is done safely.

Keep things cleaned up. This is part of your work. Don't leave tools or materials on floors, platforms, or paths where they will obstruct work and make passage difficult (See Fig. 2). Take time to keep the steps and platforms you have to use free from ice, and to knock down overhanging icicles. Take care of the odds and ends of lumber, scrap, brickbats, coke, limestone, and ore you find about the yard. The majority of falls are on the ground level and are largely caused by rubbish underfoot. Watch where you step. Do no walk through steamy places unless it is necessary; if you must go, walk slowly. Don't work where your material or tools can drop without being sure that the space below is guarded by danger signs. On the other hand, don't walk where you know that material may fall on you; remedy the condition if possible.

FIG. 8—TAKING CHANCES ON A LADDER

FIG. 9—MAN FALLS FROM LADDER

In handling material such as ties, lumber, brick, bronze, castings, molds, plates, manhole covers, pipe, barrels, boxes, scrap, and pig iron, watch that nothing falls on your foot and be careful that your fingers are not caught. A large percentage of the accidents in blast-furnace plants happen in handling material. In using bars, sledges, wrenches, picks, and other tools, remember that many accidents occur by men being struck with them. Glancing, slipping, and fallin tools cause still more accidents. In using common hand tools more skill and care is required to avoid accidents than with many kinds of machines.

Keep away from tracks if possible. If it be necessary to cross a track look both ways before starting across. If you must cross near a train, keep at least a car length from the end of the train, as it may start quickly, or there may be cars coming on the next track. Do not cross through a broken train unless the trainman motions you to come ahead or unless you are sure that there is no engine at either end. Take time to go around a train or to wait until it passes, rather than to climb through (Fig. 3). Never crawl under a car. Avoid stepping on frogs, switches, or guard rails, as your foot may be caught. Don't move material with push cars unless guarded by a flag, and when working where a car might be shoved on to you, have a flag guarding the track approach. Don't ride on engines, cars (Figs. 4 and 5), or locomotive cranes, unless your job requires you to do so.

Shoes should fit snugly about the ankle and leg, and the soles should be thick and free from holes that will allow the sole of the foot to be cut by sharp objects and protruding nails. (See Fig. 6). Whenever you see protruding nails stop and hammer them flat. In handling rough lumber, sheet tin, or material having sharp edges, it is best to wear stout gloves. For handling rough scrap wear safety hand leathers (Fig. 7), not gloves, because in throwing the scrap down the rough edges may catch in your gloves and cause a bad wrench or fall.

Ladders should be provided with spikes or nonslipping pads and when in use should rest squarely on a level surface. Grasp the sides, not the rungs, of the ladder and face the ladder in going up or coming down. Don't attempt to slide down a ladder or to use one hand to carry tools, either ascending or descending. (See Figs. 8 to 10.) Defective ladders should be taken to the carpenter shop at once.

Defective tools should be taken to the shop as soon as the defect is noticed. Do not use a sledge, hammer, pick, or hatchet that is loose on the handle, has a mushroomed head, or a split or splintered handle. Bars and wedges should also be watched, and, if any defect be noticed, be laid aside for repairs. When sledging stand on the opposite side from the man holding the bar, so as to avoid hitting him. (See Figs. 31 and 32 in following issues).

Do not meddle with electric switches, water or steam valves, or gas connections; it may cause delays and even a bad accident. Do not touch any electric line or dangling or broken wires: you may get a severe electric shock. Wear gloves when changing or cleaning electric-light bulbs. Never turn on gas, steam, electricity, or water, or set machinery in motion with which you have no regular business unless you are specifically directed to do so.

Be watchful about the furnace. Gas may be escaping in many places and may

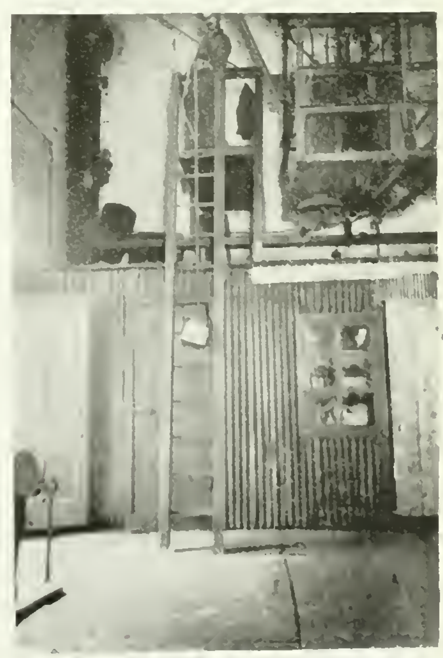

FIG. 10—THE SAFE WAY

kill you before you know it is present, the furnace may slip, the bosh or hearth of the furnace may break out, a tuyere may burst, or a blow pipe burn through, or there may be an explosion. Keep out of the cast house except when your work calls you there. The furnace crew can sometimes tell when these things are about to happen by signs with which they are familiar; at times they happen without warning. Stay at your own work and be safe. Keep away from the bottom of the dust catchers, from under the downlegs of gas mains, and off of manhole covers of gas flues. Avoid iron and cinder ladles while they are being filled, shifted, or poured. Do not go near a cinder granulating pit while it is in use and do not stand about gas burners or air doors of stoves. Never go on top of a furnace or gas washer unless under the direction of the foreman, or accompanied by some one. The tops of boiler settings, gas-engine basements, skip pits, and ore bins should be avoided unless your work take you there. Before you begin work in such places, or in any place where there is a possibility of danger, wait until the foreman has told you that it is safe to go. Satisfy yourself that the place has been made as safe as possible. Never look in the peep holes of the tuyere stocks unless it is part of your duty. Always be on watch when passing near the furnace. Remember that frequently it is impossible for the furnace men to tell when the furnace is going to slip.

Do not refuse safeguards, do not ignore rules and orders, or disregard danger signs. There is a reason for each and every one. Be sure to report every accident, even the slightest burn, cut, bruise, puncture, or substance in the eye, as this may prevent a trivial hurt from becoming a serious injury. Do not set bad examples by bravado, thoughtlessness, or negligence, for less experienced men to follow. Use common sense, foresight, and watchfulness. Those who cannot read and speak English should be urged to acquire a working knowledge of the language at the earliest opportunity. By so doing they will be in a better position to heed warnings and become acquainted with dangerous practices.

COMMERCIAL ACCURACY IN STANDARDIZED PARTS

THE wisdom of accuracy in designing and manufacturing parts was the object of some interesting remarks by F. W. Lanchester, in the course of a recent paper on "Worn Gear and Worn Gear Mounting." In the course of his remarks, he said that he had never found it cheaper to work to a low degree of accuracy than to work to a high degree of accuracy; a thrust bearing can be produced which from face to face does not differ by more than a thousandth just as cheaply as it can be produced to within two or three one-thousandths. Whatever difference of cost there may be is more than compensated for by the advantage of interchangeability. The actual production of a part accurately to dimensions that, is to say, within fine limits, may be slightly greater, but in any complex piece of machinery the saving in cost of assemblage will pay the bill many times over. * * * Some years ago, in designing certain mechanism every clearance dimension and tolerance dimension was set personally by the author's own hands, and these were worked, too, for a considerable time with satisfactory results. A new works manager, who did not believe in working to fine limits, reported that the limits were unduly fastidious and that money could be saved by relaxing the limits and so avoid having to scrap parts. The managing director consented and the scheme was tried. A slight and questionable reduction resulted in the cost of manufacturing components, but the increased cost of assembling and testing, and the cost of rectifying complaints, etc., became so great that the initial saving was swallowed up many times over. Within twelve months the scheme was abandoned and the old fine tolerances were restored, the expense of twice altering the gauges, etc., being a dead loss, apart from the disastrous results of the experiment.

EMPIRE MINERAL RESOURCES

THE extent to which the British Empire is dependent on foreign countries for the supply of certain countries for the supply of certain non-ferrous industrial metals, and methods for reducing such a condition were among the principal points dealt with by Dr. C. G. Cullis before the Society of Engineers in London last month. Of the fine leading metals, copper, lead, zinc, tin and aluminum, tin was the only one in which our position was at all satisfactory. The British mine production of tin in 1912 was 66,000 metric tons out of a world's total of 125,000, and the smelter production of 85,000. Estimating the consumption at 32,500 tons, there remained 53,000 tons for export. The closing of the German market for Bolivian tin ore had given rise to an opportunity for securing the whole of the Bolivian output for British smelting.

With regard to copper, not only were the ore resources, as at present exploited, deficient, but the smelting facilities also were seriously inadequate for the Empire's metal requirements. The production both of ores and metal could be substantially increased by suitable organisation and administration.

Lead and zinc ores, raised in British territory, had in the past been exploited on a large scale to foreign countries, notably Germany and Belgium, for metal recovery, with the result that the Empire had been placed in an anomalous position of dependence which ought never to have arisen. The shortage of zinc, in the early days of the war, and the consequent jeopardising of suppplies of cartridge-brass were referred to. The mine production of lead and zinc was more than sufficient for the Empire's requirements, but the smelting facilities were lamentably deficient, especially in the case of zinc. It was urged that all the lead and zinc concentrates of Broken Hill should in future be smelted within the Empire.

In the case of aluminum, while the actual bauxite resources of the Empire were so small that dependence had to be placed upon the French or American deposits—which were being more and more utilised in their countries of origin—large potential supplies, in the form of laterite, had a very wide distribution in the tropical colonies, but were almost untouched and untried. The systematic examination of these and other potential sources of aluminium, with a view to their utilisation, was seriously needed.

CENSUS OF MANUFACTURES

THE total census of manufactures in Canada during 1915 shows that the number of establishments has increased during the last decade from 15,796 to 21,291. The census was taken during 1914.

The total capital (including value of land, buildings, machinery, materials and stocks on hand and operating capital, owned or borrowed) has advanced from $846,585,023 to $1,984,991,427, or 134.47 per cent.

The total wages bill has likewise increased from $134,375,925 to $227,508,-800, or 69.31 per cent., and the salaries bill from $30,724,086 to $60,143,704, an increase of 95.75 per cent. The value of products in 1915 was $1,393,516,953, an increase of $674,164,350 over 1905, or 93.85 per cent.

The total value of goods manufactured for war purposes actually completed and delivered during 1915 amounted to $130,466,307, a total which it is expected will be increased by several millions in the final return.

FOUNDRYMEN'S CONVENTION AND EXHIBITION

THE Annual Convention of the American Foundrymen's Association will be held at Boston, Mass., during the week of Sept. 24. Concurrent with this meeting will be conducted the exhibition of foundry equipment and supplies, machine tools and accessories in the Mechanic's building, which affords a display floor area of approximately 80,-000 square feet.

This is the second time in the history of the American Foundrymen's Association that it has selected New England for its meeting place, the previous Convention having been held at Boston in 1902. At that time, the membership of the American Foundrymen's Association was only a few hundred, whereas at present the enrolment is considerably over 1,000. In addition to the meeting of the American Institute of Metals will hold its Annual Convention at the same time and place.

held in the turret holes and cross-slide in the usual manner.

Regarding Purchased Tools

The method of making up a list of tools as described does very well where the tools are to be made in the factory, where they can be watched, or where a complete understanding of the requirements is in evidence, but if the parts to be machined require special tools and these special tools are to be made by a firm which knows nothing at all about the conditions governing the work, a more definite description of the tools required is advisable.

In Fig. 6 is shown a form of tool sheet which emphasizes such special points which a tool designer would like to know. This sheet is headed "Specifications covering tools to be designed, etc.," the various spaces being filled in as shown. This sheet is complete in itself, and, therefore, need not be gone into fully, but special attention should be paid to the marking of the tool, the condition of the part when ready to be held in this tool and the points from which it is de-

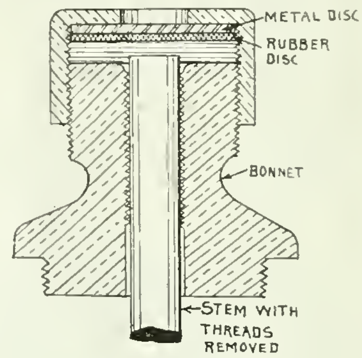
sirable to locate the parts, as the design of the tool is largely dependent on these latter conditions, in conjunction with the number of parts to be machined at one setting. The production required in one day will, of course, determine the number of tools or fixtures it will be necessary to make of the design decided upon. Any special requirements not evident from the questions on the sheet should be noted in the "Remarks" column at the bottom of the sheet.

The shrinkage of manganese steel is greater than that of ordinary steel.

HOME-MADE CHECK VALVE FOR BOILER TEST PUMPS

By J. E. McCormack.

IN the course of experiments with home-made force pumps for boiler test purposes, the writer found it convenient to utilize a couple of old globe valves from the scrap, which were quite capable of



HOME-MADE CHECK VALVE FOR FORCE PUMP.

withstanding the occasional pressure demands without break or leakage, even though not quite suited for continuous operation. Many globe valves, especially those with renewable faces, are ultimately scrapped through failure of threads, either on the valve stem or for the stuffing nut to screw on to. The failure of either of these renders the valve useless for its original purpose, but with a small amount of doctoring it will serve very well as an extemporized check valve.

The first thing to do is to grind the threads off the valve stem so that it will slide freely back and forth in the bonnet without sticking. Now remove the stuffing nut, assemble the parts together and mark the valve stem level with the top of the bonnet, cutting it slightly shorter than the mark, according to the amount of lift desired. A metal disc is now made a fairly close fit for the inside of the stuffing nut, a rubber disc being also made to fit in the same place. The sketch shows the parts assembled, but not tightened down into position. When the stuffing nut is screwed home, the rubber disc makes a tight joint with the top of the bonnet and prevents leakage from the valve stem, the lift of which may be increased at any time by cutting more off the end. Should the threads on the bonnet be badly worn, the top of the bonnet may be cut down some so that the stuffing nut will get a hold of the unworn threads. Should this fail there is frequently enough metal to allow of a standard pipe thread being cut, to accommodate a pipe cap in place of the stuffing nut.

These valves, of course, are not suited for continuous operation, but, when tried out with a force pump on boiler test work at 100 lbs. pressure, operated quite as satisfactorily as entirely new check valves.

LADDER CHAIN AND ITS MANUFACTURE

By F. Scriber

LADDER chain is quite extensively used in the make up of various hardware articles and as its name implies

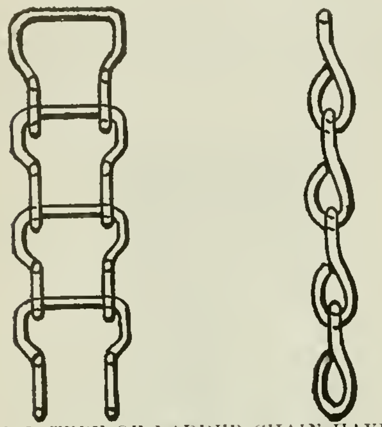


FIG. 1. TYPE OF LADDER CHAIN HAVING STRAIGHT BAR AND LOOPED ENDS.

it is shaped to appear like a ladder; contrary to most chains the ladder chain is flexible in one direction only and cannot be subjected to appreciable twisting movement. This will be readily understood by referring to the illustration Fig. 1, where it will be noticed that both ends of the wire are looped; through both loops the wire which forms the next link is passed, the straight portion on the link representing cross pieces on a ladder while the ends of each succeeding link are made to receive the next link.

As on all formed wire articles where the demand is great enough to warrant it, an automatic machine is used to make this chain, a type of machine suitable for this purpose being shown by Fig. 2, and the operations performed shown by Fig. 3. These operations consist of, straightening the wire as it comes from the reel, feeding it forward against the stop and cutting it off the correct length to make a link for the first movements; the second movement is bending the wire to shape, while the final movement is looping the ends.

As each link is completed the wire to make the next link is fed through the loops as shown in the lower view, the finished link being then released by the machine and suspended on the wire while the machine proceeds to make the second link. To clearly bring out the points involved in this operation it is necessary to follow the operations as they are performed by the machine. The various units of the machine are operated by cams and levers from the drive shaft A which is in turn driven by a belt. Referring to the illustration Fig. 4, this shows how the straightening of the wire is accomplished. This straightening process is employed to remove the short kinks which might be found in the wire as it comes off the reel and also to remove the tendency to curl which is in evidence in the wire owing to it having been tightly wound around the reel. In this exaggerated illustration it will be noticed that the wire is bent slightly as it passes between staggered rolls. These short bends have a tendency to remove the elasticity from the wire and it enters the forming machine practically straight, owing to a slight drawing action between the feed slide and the straightening rolls. This illustration shows but four rolls, and an arrangement of these rolls in two groups of seven rolls each set at right angles to each other is shown mounted on the machine at B. The wire is fed to the machine by the oscillating movement of the lever C operated by side cam D, until it strikes a gauge. The wire is now cut off and the forming operations performed by means of tools arranged as shown at the center of the machine, these operations having been described under Fig. 3.

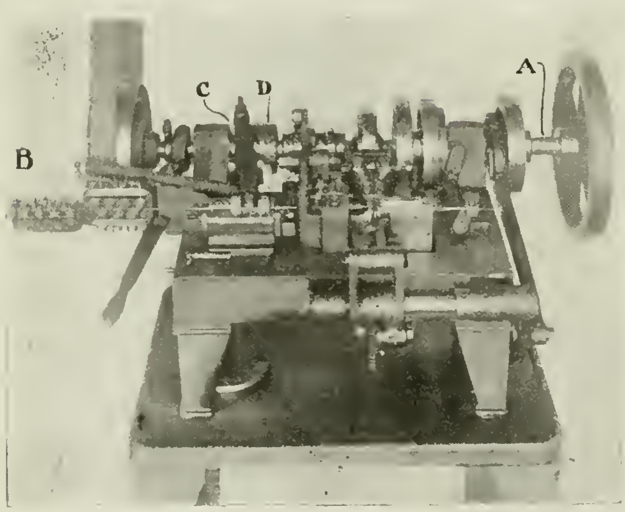

FIG. 2. AUTOMATIC MACHINE FOR FORMING LADDER TYPE OF CHAIN.

Machines of this type make ladder chain for hours at a time, with hardly any attention from the operator and, consequently, one man can run quite a number of these machines, his chief duty being to keep the machines supplied with coils of wire, as each machine is supplied with an automatic stop motion for stopping the machine in case the wire should break, and in addition to this these machines are sometimes provided with a bell to call the operator's attention to the fact that the machine has stopped owing to it having run out of wire or something having gone wrong.

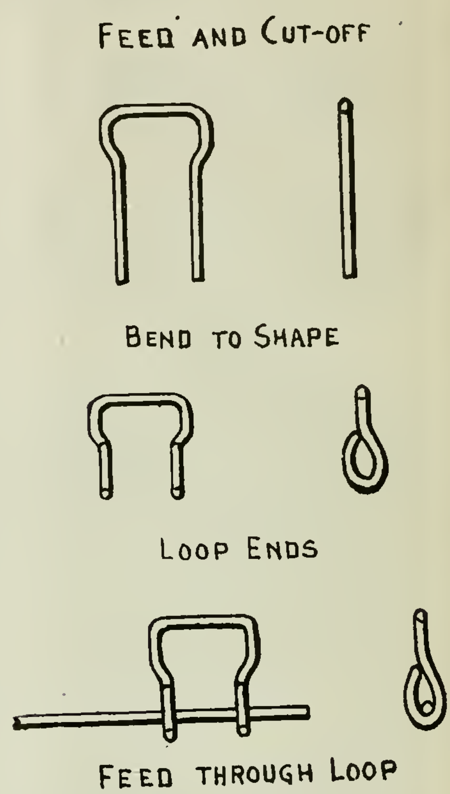

FIG. 3. SEQUENCE OF OPERATIONS PERFORMED IN MAKING LADDER CHAIN.

Belt Dressing.—The operation of applying dressing to belts to prevent them from slipping leads to many serious accidents. Care should be taken to apply the dressing at the point where the belt leaves the pulley and to roll up the sleeves so that they will not catch upon belt fastenings or other parts of the belt. It is hardly feasible to stop the belt while the dressing is being applied, because it is then very hard to reach all parts of the belt, and to apply the dressing smoothly and uniformly. The safest and best way, without doubt, is to remove the belt altogether, when it needs dressing, and stretch it out along a bench or on a clean floor.

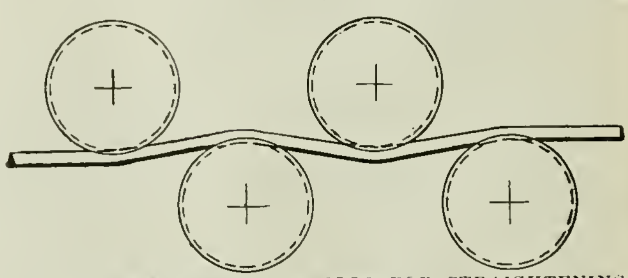

FIG. 4. ARRANGEMENT OF ROLLS FOR STRAIGHTENING WIRE AS IT IS FED INTO MACHINE IN FIG. 2.

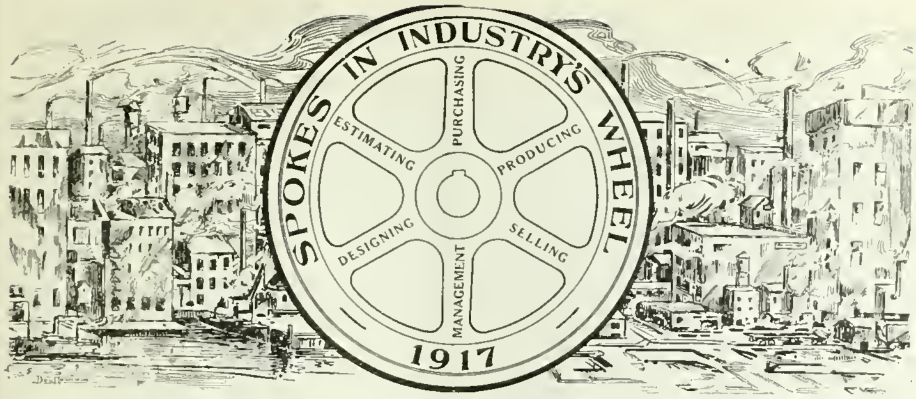

The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

FRED W. EVANS

IN these days of specialization, when the principal argument in favor of many machines is the feature of "single-purposeness," it is pleasing to turn from the material to the human side of affairs and observe that many in our midst are possessed of this qualification. It is hardly correct, however, to apply this attribute to the subject of these remarks, in its strictest sense, as in order to be single-purposed, he has been many-minded. The former fact is emphasized, however, because, with the exception of some three years spent in gleaning information of a practical and ultimately useful nature, Fred W. Evans has spent his entire career in the service of the Canadian Fairbanks-Morse Co., his duties with this concern having run the whole gamut of activity from ubiquitous junior assistant to the position of branch manager for the company at Toronto.

Fred hails from Montreal, a son of real Canadian soil, having been born in that city on December 8, 1885, of English parents, and, therefore, fully qualified to further in every way the interests of Canada and the British Empire. His early education was obtained at public school, followed by a business college course, after which he spent a few years in the car department of the Grand Trunk Railway system, where he obtained an insight into many of the mysteries of rolling stock. Had Fred been destined for a financier, he might have been tempted to include the watering of stock also as part of his duties, but he smilingly denies any knowledge of that species of railroad engineering.

Be that as it may, Fairbanks-Morse roped him in on June 20, 1904, and have clung to him ever since; and the association has been pleasant and profitable to both parties, as all of his friends know. These same friends, from coast to coast, were glad indeed when his appointment as manager of the Toronto branch was officially confirmed at the close of the past year. They were all agreed that Fred was a good scout, a real brick, but they did not know perhaps that Fred had absorbed the solid brick quality in his childhood days—his father, Thomas Evans, having been a building contractor, so Fred had every opportunity for distinguishing between the real and otherwise bricks. Perhaps the fact that his father erected chimney stacks and other architectural structures gave him early facility for cultivating the lofty gaze and broad view—termed high ideals by the

FRED. W EVANS

philosophers anyhow. C. F. M. Co. jumped him around the Dominion in good shape, whilst most of the neighboring States have had the honor of supporting him on frequent occasions.

While learning the rudiments of the business in a general way our youthful friend was connected with an incident which, perhaps, more than anything else, is responsible for his presence in the machine tool business to-day. As a matter of fact, Fred broke his way into the machine tool department of the company literally as well as metaphorically. While admiring the beautiful workmanship of a Brown & Sharpe milling machine one evening in the warehouse after hours, his high ideals came to the surface, and Fred tried to see how high the table would elevate. The elevating gear worked like silk, and being single-purposed, he did not worry about anything else but getting that table up high, till snap went the arm braces, and Fred's heart went to his boots; in fact, he swears he didn't have a wink of sleep all night after it.

The next day his heart left his boots altogether when he heard the manager of the department say that if the culprit did not own up, he would be fired. By noon time Fred's heart was in its normal location, and he told the truth so frankly and convincingly that he was invited to be one of the elect and dwell in the region of machine tools which are never out of truth—at least the kind Fred sells, anyway.

The fall of 1910 found Mr. Evans in Winnipeg, where his good nature was imposed on to the extent of acting as consulting equipment engineer for the Winnipeg Technical School, a valuable service on his part, which was duly appreciated in contract form, covering most of the machine tool and wood-working equipment of the institution.

The outbreak of war resulted in his return to Montreal, where he assumed entire responsibility for his firm's machine tool business throughout the Dominion, a task which rapidly assumed very large dimensions as a result of the company's dealings with munition manufacturers, and which was doubly difficult because of the experimental stage through which everything and everybody were then passing.

Munition developments in the Toronto field resulted in his joining the staff there in the fall of 1915. In March, 1916, he was appointed acting manager of that branch, and recently was confirmed in that position as permanent successor to his late friend and predecessor, Capt. Frank Newman.

Although a comparatively newcomer in the Queen City, Fred dwelt here in spirit years ago—perhaps that's why he liked to speak so much of the "Queen" City. Mrs. Evans was formally Miss Edna M. Hurd, of Toronto, and has shared Fred's roof, rain, and shine since June 8, 1910, their residence at 75 Indian Grove, Toronto, being enlivened by the presence of two sons.

Well on the right side of forty, Mr. Evans takes a keen interest in the rising generation. A strong admirer and advocate of all Y.M.C.A. activities; a keen participant in out-of-door sports; an ardent motorist; an out-and-out square dealer with everyone, Mr. Evans is, in addition, particularly qualified to appreciate the requirements of the future workers in engineering circles. "The duties of employers toward their youthful employees only begin with the payment of wages. The future of each one of them will be largely influenced by the treatment meted out by his first employer. Knowledge must be acquired rapidly and permanently if future promise is to be fulfilled. Assisting apprentices to obtain ample and up-to-date equipment of tools is one way in which firms may secure faithful and lasting service, but present and future developments render technical study almost more important. The modern technical journal is a vade mecum for all progressive spirits, whether in sales force or shop, and as an exchange medium for ideas, possesses a value which must sooner or later be more fully recognized by employers and employees. The sooner the better."

SCREW-CUTTING IN ALUMINUM

THE cutting of perfectly clean threads in aluminum, either by machinery or by hand-power, is a problem which has tried the patience of many an engineer. In a screw-cutting or a tapping machine, the metal tears away, notwithstanding the lubricant hitherto used, and a large proportion of the threads are destroyed in the process, or are imperfect. When cutting the threads by hand power—a kind of hard labor when the lubricant used is unsatisfactory—the same defects generally occur, or when they do not, the threads are not clean and uniform throughout, for the point at which the man stopped to give another fraction of a turn to the screw or die-stock is marked by dents and raised portions on a series of the threads and over the whole threaded depth. Such difficulties, however, generally give way in time to patient experimenting, and in this case they appear to have done so, for quite recently we had the opportunity of seeing inside taper-threads cut with cleanness and accuracy by the aid of a new lubricant. The job in hand was an order for aluminum adaptors for shells, and naturally ran into very large numbers. Under the old conditions it was slow and not satisfactory, but with the new lubricant the adaptors were turned out at the rate of sixy to seventy per hour by two boys. The lubricant also increases the life of the screw-taps, one pair we saw having cut as many as 7,000 aluminum adaptors. This lubricant is also of great value for other processes in the manufacture of aluminum articles, especially turning and machining, a great increase in output being obtained.

CANADIAN PULP AND PAPER

THE progress that Canada is making toward becoming the world's centre for the manufacture of pulp and paper is indicated in figures recently published by the Department of Trade and Commerce. For the year ended July, 1916, the exports of paper amounted to $21,678,868, of which 88 per cent. went to the United States and 5.2 per cent. to the United Kingdom. This total is an increase of 31 per cent. over the figures for the year previous. The rate at which this business has grown in Canada will be appreciated when it is realized that the first export shipment of paper from Canada was made in 1892, amounting to a total of $91 for that year. The total exports for 1902 were but $24,000, and for 1913 only $6,327,000.

Taking the situation as a whole the total exports of paper, pulp, and pulpwood for the fiscal year ended July, 1916, were $40,865,266, of which the United States received 87 per cent. and the United Kingdom 5 per cent. The increase over the previous year was 27 per cent. On the other hand, Canada imported, during the year ended July, 1916, $6,327,298 worth of paper and manufactures of paper.

The foregoing facts, in conjunction with the use by Canadian pulp and paper mills of nearly $9,500,000 worth of pulpwood, indicate the tremendous drain upon our pulpwood resources, according to a statement issued by the Conservation Commission. This drain is likely to increase rather than diminish in view of the rapid depletion of accessible supplies of timber, suitable for pulpwood in the United States. If this great source of national wealth is to be perpetuated, much more stringent measures than in the past must be taken to prevent destruction by fire and to ensure the restocking of valuable species of cut-over and burned-over areas.

Silvering Brass for Lacquering.—It often happens, in finishing ornamental work, that silver bands or reliefs are needed, the thickness of the silver, of course, being a minimum. To make a good and efficient solution for the purpose, dissolve 1 oz. of good nitrate of silver in a quart of distilled water, and in a separate vessel make a semi-saturated solution of hyposulphite of soda. Add sufficient of the hyposulphite solution to the nitrate of silver solution to throw down the silver as a brownish precipitate, agitating the liquid; then add, drop by drop, sufficient of the hyposulphite to re-dissolve the precipitate, and after this is secured add a slight excess of hyposulphite. Store in black or other non-actinic glass bottles, well corked. To use, apply to the clean metal with a sponge or brush, and rinse off with clean water, and dry thoroughly before lacquering.

Harmony in organisation is something that will make success against many adverse conditions, and the lack of it will generally ensure defeat, regardless of all other conditions. The thoughtful work of each man is the real progressive work, and although this is stimulated by a wholesome rivalry, it is wholly checked by strife.

Life is simply a matter of concentration. You are what you set out to be. The things you read and think to-day are the things you become to-morrow.

STEEL PLANT EXTENSIONS IN 1916.

FROM statistics compiled by a U.S. contemporary covering steel plant improvement and extension, during last year, the following data pertaining to Canadian establishments is available:

The Algoma Steel Corporation, Sault Ste. Marie, Ont., added a 32-in. billet mill. In the duplex plant, two 75-ton stationary open-hearth furnaces were also built. This year a 75-ton stationary open-hearth furnace will be constructed and also a heavy structural mill.

The Dominion Iron & Steel Co., Sydney, N.S., has under construction a new 400-ton blast furnace. Contracts have been awarded for 120 Koppers byproduct coke ovens with a capacity of 11.2 tons of coke each in 24 hours.

The Steel Company of Canada, Hamilton, Ont., completed and put in operation three 75-ton open-hearth furnaces and doubled its soaking pit capacity. It also made large additions to its shell-forging plant. At its Montreal plant a large addition was made to the shell-finishing plant. A new 75-ton open-hearth furnace is under construction.

The Canadian Car & Foundry Co., Montreal, Canada, made such additions to construction and equipment as were necessary for the furtherance of munition work, but the company does not consider this as capital expenditure. Over $1,000,000 has been spent or authorized on this line of work, although it is not considered as of a permanent character.

The Canadian Car & Foundries, Montreal, built at its Welland, Ont plant two new 25-ton basic open-hearth furnaces, making a total of four, and is now building two more to be completed next month. It has also installed a 1,000,000-gallon oil storage tank and built a new forge shop for forging 5000-4½-in. shells per day. At the company's Longue Pointe works, Montreal, one 25-ton acid open-hearth furnace was built, making a total of four. Another furnace of the same type is under construction to be completed this year. At the Point St. Charles plant, Montreal, one more furnace is contemplated. The company is installing there a forge shop for making 6-in. shell forgings at the rate of 4000 per day, commencing March 1.

The Nova Scotia Steel & Coal Co., New Glasgow, N.S., is erecting a new blast furnace Sydney Mines, N.S.

The Manitoba Steel Foundries, Winnipeg, Man., has practically completed its new foundry. It will make electric steel both in the form of castings and ingots for rolling and will have a capacity of 8000 to 10,000 tons per year.

The Pacific Steel Products , Ltd., Bridgeport, B.C., is constructing a new open-hearth steel furnace and installing machines for turning out railroad spikes, bolts and nuts.

TWIN MUFFLE FURNACE FOR HARDENING HIGH SPEED STEEL.

ONE result of the advent of munitions manufacture has been a very complete realization of the value of high speed steel not only economically when performing its duties as a manufacturing accessory material, but also intrinsically when values are increased and wastage prevails through defective treatment and careless usage.

It is an actual fact that the shortage of this material which was threatened some time ago was in part due to carelessness and lack of facilities for proper hardening and in the course of events it was but natural that the onus of the situation would gravitate towards the makers as the source of the material. As the leading makers of high speed steel in this country, Armstrong Whitworth, Ltd., Montreal, were in a unique position to appreciate the factors of the situation, the result being that they have developed, and are now marketing a hardening furnace for high speed steel which enables the full benefits of this material to be obtained by the average user.

The furnace is of the twin muffle type and oil-fired, the appearance and construction being clearly indicated in the accompanying illustrations. Fig. 1 is a front view, the two chambers being of solid fire brick construction, built into an angle iron frame work, the whole being carried on a braced frame of the same material. The internal design is shown in Fig. 2. An opening A is provided at the back of each chamber, through which the oil and air mixture enters, the flame impinging on the curved surface of baffle brick B whence it proceeds around each side of the chamber and underneath the hearth C, finally

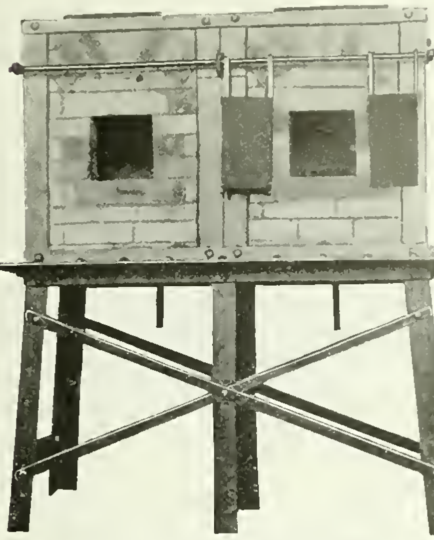

FIG. 1—FRONT VIEW OF TWIN MUFFLE FURNACE FOR HARDENING HIGH-SPPED STEEL

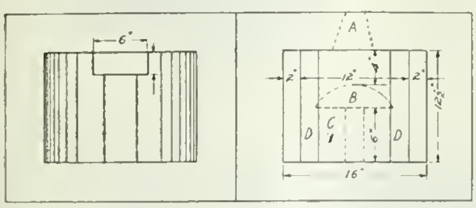
ascending past the semi-muffle walls D to the rectangular exit in the arched roof. This arrangement prevents the products of combustion from coming in contact with the work and insures a very even degree of heat throughout the chamber.

The twin chamber arrangement provides ideal conditions for the hardening of high speed steel. The left hand chamber is used for preheating purposes only, the steel being slowly and evenly heated to about 1400 deg. F. when it is transferred to the right hand chamber which heats it quickly to 2,200 deg. F., or over if necessary, to be followed by such quenching as is required by the material.

Individual control is provided for each chamber, and low pressures are employed, the air being at 2 lbs. per sq. in. and the oil at 10 lbs. per sq. in., so that gravity feed can be used in the majority of installations.



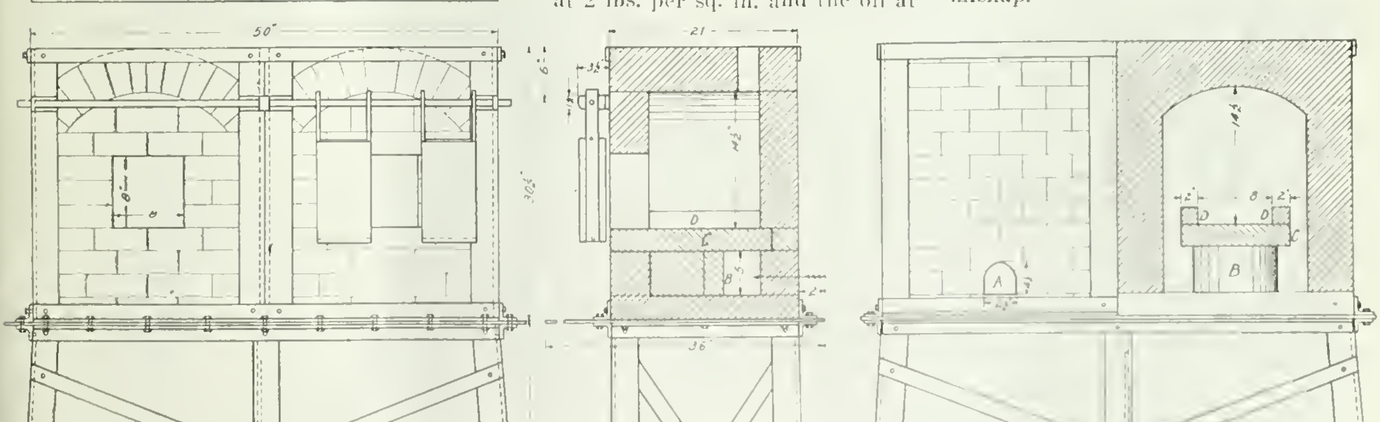


FIG. 2.—DETAILS OF CONSTRUCTION OF TWIN MUFFLE FURNACE.

CONTROLLED ESTABLISHMENTS AND SECRECY

THE British Minister of Munitions appeals to the owners of controlled establishments, to all persons responsible for the management of such establishments, and to the public generally, to guard against communicating to neutral countries information concerning controlled establishments, the effects of control on the conduct of their business, and the character and quality of munitions work in hand. Such information is sometimes conveyed (probably by inadvertence) in replies to inquiries as to whether particular establishments are able to undertake particular classes of work, and also in advertisements in newspapers which circulate abroad. The public are warned that no communications of any kind can be transmitted abroad if they give any indication that a firm is controlled or is engaged in munitions work, or if they contain information with respect to the manufacture, output, or supply of munitions, or with respect to the place where such work is carried on.

DON'T try to remove dirt or cuttings from the small bore of a revolving piece of work, with the fingers. It is a serious thing to have a finger twisted off.

DON'T force a chuck or face plate on a threaded spindle when you find there is dirt in the screw. It may happen that the thread will seize, and cause considerable trouble to remove.

DON'T allow the sleeve of the shirt or jacket to come in contact with revolving lathe work or shafting. Even the smoothest of shafts will take hold of clothing, often resulting in serious mishap.

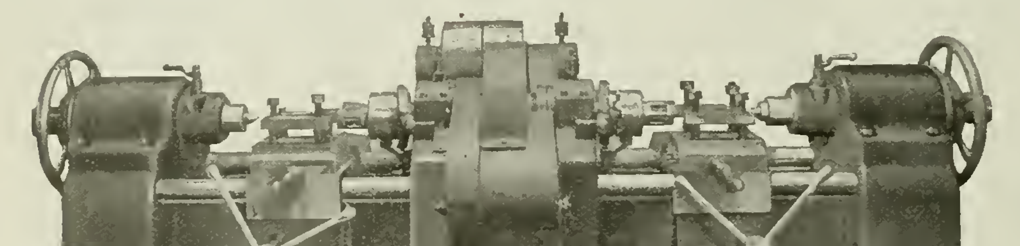
PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

DUPLEX SHELL LATHE

WITH the primary object of speeding up production, the Dominion Machinery Co., Toronto, have developed a duplex lathe, in which two shells can be rough turned at one time and by one operator. The lathe, however, is so designed that the shells can be machined individually or together. This is one of the principal features of the lathe, and it is accomplished by means of two separate steel jaw clutches on the main spindle located on either side of the centre driving head. Briefly, it is a modification of an axle lathe adapted for producing shells.

The lathe is of substantial construction, and for this reason is particularly suitable for shell rough turning operations. It will take shells ranging from 4.5 in. to 6 in., and tests have shown 120 4.5 in. shells can be rough turned in ten hours by one operator. The lathe is built for belt or motor drive, and the clutches obviate the necessity of stopping the machine when chucking. The main spindle is mounted in heavy bronze bearings, and is driven in the centre through triple gears with a ratio of ten to one. At each end of the main spindle is fitted a steel jaw clutch. The driving section of each of which has a square recess for receiving and revolving the chuck. The chucks used on this lathe are of special expanding roller type, and are independent of the lathe. The chuck is placed inside the shell, which is placed between the lathe centres. The chuck fits in the square recess on the clutch, and the base of shell, being countersunk, is carried on the tailstock centre. The chuck is so constructed that the deeper the cut the tighter the shell is held on it.



DUPLEX SHELL LATHE FOR ROUGH TURNING OPERATION

When the clutch is thrown-in, the shell revolves and the feed is started. The same operation is then performed on the other side of the lathe.

Both carriages are driven independently with positive worm drive, they are also fitted with hand feed. An automatic trip is provided for the carriages which stops the feed at the end of the cut. A considerable saving in floor space has been effected in relation to the output, and the lathe has been designed with all parts in excess of the most exacting requirements. The lathe in working order weighs approximately 8,000 pounds.

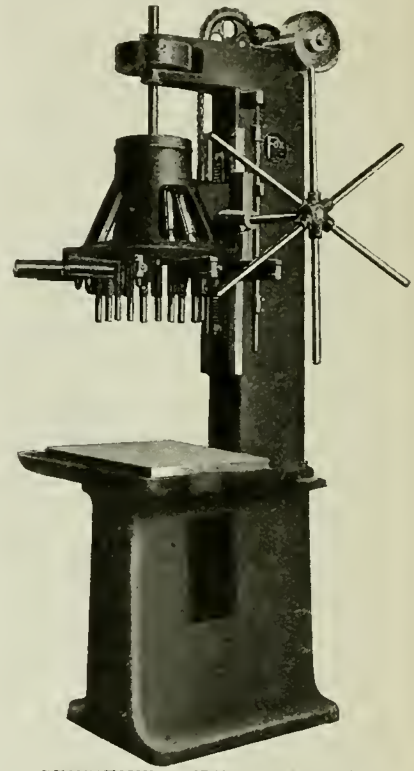
SENSITIVE MUTIPLE SPINDLE DRILLING MACHINE

THE accompanying illustration shows a regular type of small, sensitive, multiple spindle drill which has been designed for light drilling, countersinking, etc. The table is cast separate from the base when required.

Either 9 in. or 12 in. round heads can be furnished, the former being equipped with from 2 to 10 spindles of 1 in. dia., and the latter with from 2 to 16 spindles of $\frac{3}{4}$ in. dia. A six-armed pilot wheel, keyed to rack pinion shaft gives sufficient leverage for easy drilling, the rack pinion being heat treated and keyed to pinion shaft. All pinions are of .30 carbon steel with double bearings integral with pinions, and running in oil. Roller bearings are used in the idler pulleys and the drive pulley on the vertical shaft runs in bronze bushed bearings; ball bearings are provided for end thrusts.

The universal joints are of a patented type composed of three parts only, two forks milled from the solid and a centre block of similar construction, dispensing entirely with pins, screws or rivets. These parts are hardened.

Crucible steel spindles are employed



SENSITIVE MULTIPLE SPINDLE DRILLING MACHINE.

a new type of adjusting arm permitting rapid adjustment and rigid support. Special cluster plates are supplied when required by the makers, the Fox Machine Co., Jackson, Mich.

SCRAP RECLAIMING PRESS

THE development of the Southwark Gross press marks an important step toward the solution of many railroad shop problems connected with the reclamation of scrap material from wrecked cars and general repair work, the rapid and almost universal adoption of all-steel equipment having rendered largely inadequate the former press equipment which was only adapted to the needs of wooden cars.

Its usefulness, however, is not limited to railroad needs, as the necessity for a press of this type has been constantly growing in many branches of iron and steel industry, the accompanying cuts serving to convey some idea of its adaptability to the needs of general manufacturing and repair work.

The base of the Southwark Gross is a heavy steel casting with a flat surface which forms the foundation for the structural steel frame, consisting of two steel uprights which support a main cross frame. The top of this framework is braced by heavy tie rods attached to the four corners of the base platen.

The pressure cylinder is suspended from the cross frame by means of a four-wheel carriage, while the travel of the ram is controlled by means of a specially balanced type of four-way valve located in a position convenient to the operator; the carriage is propelled backward and forward across the top frame by an endless chain traveling over sprockets.

The guide for the piston rod is held between two angle irons fastened to the vertical columns. The piston of the pressure cylinder is 20 inches in diameter and has a stroke of 36 inches. It is packed with leather cup packing which can be quickly renewed when necessary. The end of the piston rod is fitted with a die which can be changed in a manner similar to the die of a steam hammer. Air is supplied to the double-acting cylinder by flexible hose connections so arranged and sufficiently long to permit free movement of the cylinder as it travels across the table.

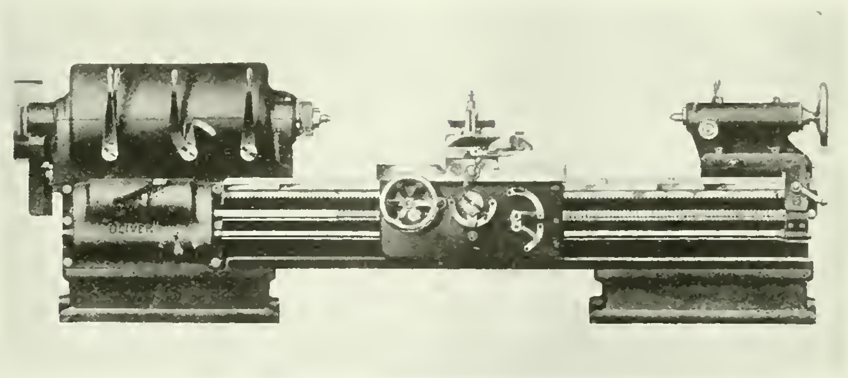
Dies of great variety can be used and new dies made at any time to meet special requirements. While in most instances the work requiring bending or straightening can be handled cold, in some few cases with extra heavy parts it may be necessary and safer to heat the work before subjecting it to a pressure of fifteen tons which is the capacity of this press. Bending parts of this description while cold is likely to result in cracking. However, with the modern means of welding, such as the oxyacetylene torch and other processes, these cracks are not serious and may be more quickly remedied and defective parts made sound at less cost than they could be either straightened or reclaimed by the obsolete processes formerly in use.

The builders of this press are the Southwark Foundry & Machine Co., Philadelphia, Pa.

EXTRA HEAVY DUTY 26 in. ENGINE LATHE

PROPER distribution of weight and correct proportioning of mechanism are features which have received particular attention in the 26 in. engine lathe illustrated herewith. It is intended to meet satisfactorily all the demands of extra heavy duty resulting from the use of the most efficient tool steels.

The heavily ribbed headstock has an unusually long bearing on the lathe bed and has a 6½ in. x 10 in. front bearing for the spindle, with 4½ in. x 7 in. at the rear. It is of the all geared design with single pulley drive, giving 12 spindle speeds from 8 to 300 revs. per min. The spindle is lubricated by large oil chambers feeding through felt wipers, while a hole large enough to pass a 3 in. bar is provided. High carbon steel is used for the spindle which runs in two piece replaceable bronze bearings adjustable for wear. Large diameter cast steel gears are entirely enclosed, and run in oil, all pinions being of forged steel.

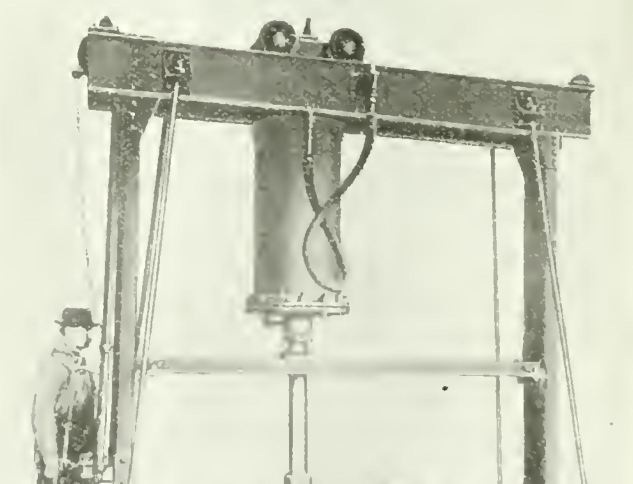


EXTRA HEAVY DUTY 26" ENGINE LATHE

The tailstock spindle is 4 in. dia. and is locked by clamps acting on two sides, while 4 large clamp screws with hardened nuts secure the tailstock firmly in place. A geared crank is provided for moving the headstock along the bed. Both spindles are fitted with No. 6 Morse taper centres.

The bed is of refined box type design with liberal support form box column

RECLAIMING PRESS FORMING HOPPER SHEETS FOR STEEL CARS.



STRAIGHTENING BENT DRAW-HEADS IN RECLAIMING PRESS.

pedestals without any overhang. The width across shears is 24¾ in. braced by closely spaced box sections, the width and depth of the bed being sufficient to prevent spring under the heaviest cuts.

The carriage has an over all length of 40 in., with a 12 in. bridge. Taper gib adjustment is provided both on cross slide and compound slide, these and the carriage being scraped to perfect bearings on their respective parts. The compound slide is presented at an angle of 30 degrees, providing a more solid bearing capable of easier manipulation. Felt oil wipers on shears, micrometer dials, chip guard and thread dials are evidence of the completeness of detail.

The double plate box type of apron provides bearings at each ends of the feed gear shafts, the front removable plate permitting access to the mechanism without removing the apron from the carriage. The friction drive on both longitudinal and cross feeds is controlled by a single lever so that both feeds cannot be thrown in at the same time, while none of the feed mechanism can be put into gear when the lead screw is in operation.

The 2¼ in. lead screw has 2 threads per in. and engages with two bronze half nuts. Thirty-three threads ranging from 1 to 16, and a similar number of feeds from .013 in. to .333 in. per revolution of spindle are obtained through the gear box, which is fitted with steel gears and bronze bushed bearings, the gears being changeable while running.

A double friction type countershaft is usually furnished, and the headstock is designed to readily accommodate a driving motor. The regular equipment includes one steady rest, one 26 in. face plate, one 12 in. face plate, with centres, wrenches, cranks and countershaft. Extra equipment includes fittings for motor drive, taper attachment, follow rest, square tool post, hexagon turret, and self-contained gib crane. Weight crated, 12,600 lbs.

The builders of this lathe are the Oliver Machinery Co., Grand Rapids.

SCREW MACHINE EQUIPMENT

CONSIDERABLE changes have been effected recently in the No. 5 screw machine built by the Foster Machine Co., Elkhart, Ind., calculated to increase the ability and scope of the machine to a marked degree. Two styles of this machine are now offered, one with back-geared cone head, and the other with an all geared head, the latter being shown in Fig. 1 complete with new bar equipment.

In order that the efficiency and productive capacity of this machine can be utilized to the maximum extent, the makers have designed a very complete line of tools, so that not only can the production, on what is commonly regarded as screw machine work in its narrow sense, be increased to a considerable extent, but the general range of work which can be handled to advantage is greatly increased, and includes practically all kinds of chucking work within the capacity of the machine.

One of the outstanding tools for bar work is the roughing box tool or single cutter turner, of which a new design has been gotten out for this machine. The cutter is located radially to the work, so that it is ground on the end when being sharpened, economizing tool steel. Back rests of the roller type, with hardened and ground rolls and roll studs, are mounted on independent slides which are adjustable by means of a graduated screw. The cutter slide is equipped with a release to prevent marring the work when withdrawing, the release being operated by a lever handle in front of the tool, which also binds the cutter slide rigidly to the tool body, a graduated dial being provided for setting the slide operating screw. A multiple cutter turner, a pointing tool and a new design of adjustable hollow mill are further items in the bar stock group. The hollow mill is shown at right, Fig. 2, and is specially designed for rapidly removing a large amount of stock on comparatively short work, having the desirable feature of being easily adjustable for different diameters. The multiple cutter turner is a tool for turning more than one diameter at the same setting. Back rests similar to the single cutter turner are used, while the cutters are held in supports so that they may also be shifted to and secured in any desired position on the body casting. When desired, this tool can be equipped with three double tool holders for taking up to six cuts simultaneously, shoulders only ¼ in. apart being formed with it.

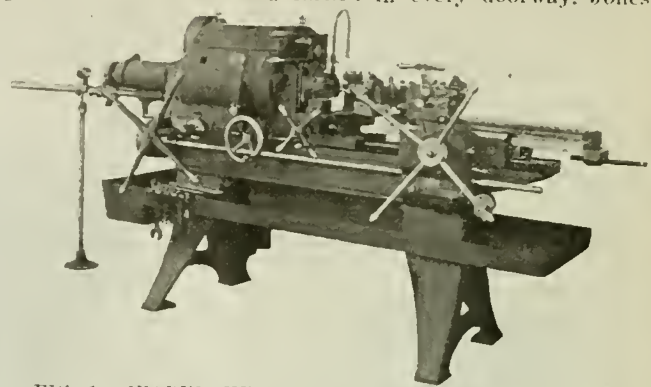


FIG. 1. GEARED HEAD SCREW MACHINE WITH TOOL EQUIPMENT FOR BAR WORK.

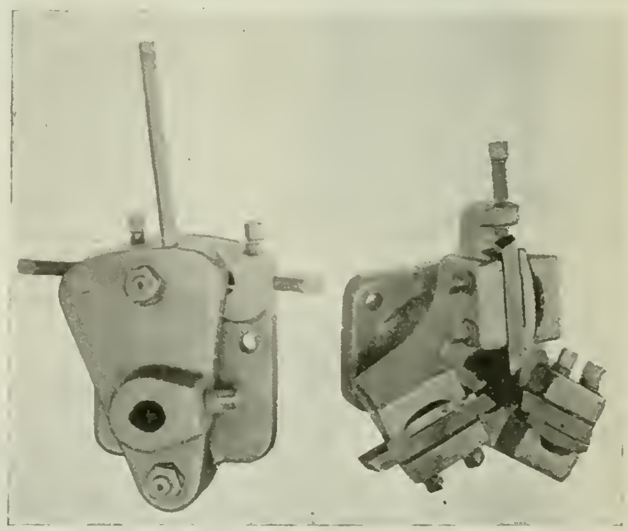

FIG. 2. LEFT, RECESSING TOOL. RIGHT, HOLLOW MILL.

In connection with chucking work, an interesting tool is shown at left, Fig. 2, this being particularly well adapted for recessing and back facing, also for boring work in small quantities. The tool is carried in a quadrant shaped member hinged on the front of the main casting, the pivot on which it swings being located below the cutter. It is operated by the handle shown, two stop screws being provided for adjustment and stop purposes at each limit of travel.

The variety of equipment is well rounded out by a large selection of miscellaneous tool holders and adapters, cut-off slides, drill, tap and die holders.

FLAG DAY INCIDENT

IT was "Flag Day." Beauteous vendors pressed their wares at every street corner and lurked in every doorway. Jones threaded his way through the city streets and arrived at the offices of that old Scotch firm, Duncan, M'Haggis and Fraser.

Mr. Duncan, he was told, was out, but the other two partners were in, and he was presently ushered into an inner sanctum, where he found M'Haggis and Fraser sitting on either side of the fire and looking distinctly disconsolate—not to say hungry.

"It's really Duncan I want to see," explained Jones, "but since it's about lunch-time I thought we might all go out together, and I'd come back with you and talk to him afterwards."

"I am sorry," said Fraser dourly, "but we canna come out to lunch."

"What—aren't you going to have any?" asked Jones in astonishment.

"Aye, aye—but we must bide a wee—Duncan has the flag."

Affidavit Forms for Importers.—The Trade and Commerce Department, Ottawa is issuing to all Canadian importers a form of affidavit to be made out before shipment of restricted goods from the United Kingdom can be made. The affidavit will contain information such as quantity and description of goods ordered, use to which they will be put, etc.

Vol. XVII. JANUARY 25, 1917 No 4.

AN EVENTFUL WEEK

THE past week has been in many respects an eventful one, having to its credit and otherwise the issuance of an exposition of idealism in affairs international by the President of the United States; the destruction by fire and explosion of a British munitions factory with attendant serious loss of life; the unfolding of a tale of shipping tragedies through the instrumentality of a German sea raider, and official intimation that the Imperial Munitions Board have determined to erect immediately a mammoth steel plant in our midst for the more intensive production of munitions. It may be said, relative to each of the foregoing, that there is much food for thought, and while the last named appeals to our commercial sense, at least, in manner to excite satisfaction, it cannot be so said of the other happenings. If we add to the list the impressive stride that stocks and particularly war stocks have acquired in the direction of saner and real-value levels, then it must be admitted that this New Year, 1917, is off to a spectacular if ill-assorted start. Concurrent with the break in stock exchange values, it is quite in order that manufactured products, whatever their constituent or purpose, should evidence a like material shrinkage, and we are of opinion that such an eventuality is a near-future possibility, if not immediately imminent.

Practical peace will come before the idealistic, therefore grim work must perforce be yet performed. Idealism at this juncture is synonymous with being scared.

HIS MAJESTY'S CANADIAN TORPEDO BOAT "GRILSE"

IN our December 21 issue, reference was made editorially to the specially trying experience from which His Majesty's Canadian Torpedo Boat "Grilse" and the majority of her crew had just emerged successfully. We have been asked by Lieut. J. K. L. Ross, R.N.C.V.R., former owner and commander of the vessel, and by whom with a commendable patriotism she was handed over to the Canadian Department of Naval Service, to state that the illustration which appeared on page 647 did not represent the "Grilse," also to correct some inaccuracies in the text matter. This we take pleasure in doing by publishing his letter which will be found on page 74 of our present issue.

The writer being familiar with the appearance of the vessel—having seen her "war dressed" on several occasions, has no hesitation in stating that the photograph received from Lieut. Ross, along with his letter, is more truly representative of the "Grilse" than that published previously by us. We, however, to avoid a possible clash with the Censor, did not positively identify the craft, the underline to the illustration having the qualification—"Speed Pleasure Yacht." Further, and to quote direct from our previous editorial, it was stated that—"to those unfamiliar with the appearance of the vessel, a very good idea is to be had from our illustration." Referring to Lieut. Ross' letter, and the survey report on the vessel, we may state that the name of the gentleman who furnished the latter has been given us. He is personally known to the writer and is well qualified to pronounce authoritatively on such craft as the "Grilse" and on war vessels generally, as well.

We are further advised by Lieut. Ross that during his twelve months' command of the "Grilse," "they were out in all weathers, and on one occasion I took her through a cyclonic storm near Bermuda, it being necessary then to keep to sea for nearly a full week. Nobody was hurt aboard and not a rivet was started. It was uncomfortable," he states, "as all destroyers are, but I always felt confident that the 'Grilse' would weather any storm if navigated carefully." The vessel is over 200 feet long, not 175 feet. She was built by Yarrow's Ltd., and not by Thorneycroft. Regarding her builders, for record purposes, the information is desirable; as indicative of high quality product, however, no distinction may be drawn between the two builders named, our views in this respect being clearly evident from the opening sentence of our previous editorial which we here quote: "The fact that H.M.C. torpedo boat 'Grilse' managed to make port after being battered and bruised to the point of foundering with all aboard is due in the first place to her soundness of construction at the hands of her builders, and secondly to the herculean efforts of the crew to keep her afloat by hand pumping and baling, even when all hope of rescue seems to have faded."

Readers of our journal will appreciate Lieut. Ross' desire to put before them the facts bearing on the "Grilse" construction, transfer, and his own service as her commander, and will concur with us in the opinion that, so far as he is concerned, neither effort nor expense were spared in the performance of his patriotic act. We still think, however, that poor judgment was displayed by those in authority in putting the "Grilse" to sea—especially on the North Atlantic in mid-winter, and while we do not hesitate to stand alone in so expressing ourselves, we are pleased to state that we have the unqualified support of perhaps the most prominent authority on light craft construction and exponent of their navigation on this continent.

We should have been pleased to publish the photograph of the "Grilse" in her "war dress," but the Censor is unrelenting. Lieut. Ross fully appreciates the situation in this respect, as will also our readers.

BALKING "SAFETY FIRST"

APROPOS of the snuffing-out of a useful life, the more or less serious injury received, and narrow escape with life and limb, by a goodly number of others, on the occasion of the departure of a troop train from the Union Station, Toronto, on the night of January 21, it seems opportune to point out to our railroad managements as well as to our military authorities the necessity of their rebutting the all too prevalent tendency of civic administrators to "butt-in" and largely set aside an otherwise well ordered and successfully applied "Safety First" propaganda.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., Jan. 22, 1917.—Industrial interests are again resuming the activity that was recently disturbed by international developments. The attitude of Britain however, has added confidence to the situation. Freight congestion has been somewhat relieved but is as yet not all that might be desired. Severe storms are adding to railroad troubles and delivery of material is very indefinite.

Pig Iron

The general market is unchanged, the quotations having undergone no advance during the week; railroad troubles are effecting transportation and some furnaces are operating light.

Steel

The production of steel at the present time is being greatly curtailed through the difficulty of seeing the required raw material with which to carry on operations. The scarcity of coke has resulted in the temporary banking of several furnaces, and transportation troubles add to the discomfort of steel producers. The relief that was offered last week through the decline in coke has again reacted and coke is now selling at $10, an advance of $1 per ton. More active inquiries are in the market and the general situation has recovered from the scare that loomed up some few weeks ago over the possibility of peace negotiations. The demand for billets and steel bars is as insistent as ever and the supply is not sufficient to meet the trade requirements. The construction of many factories and buildings maintains a good demand for structural material. The unsatisfied demand for steel plates by ship and car builders may shortly result in further advances on these lines. Inquiries for sheets are not so heavy but the relief is acceptable to the mills under their filled up condition. Local prices have nominally advanced on black sheets and Premier galvanized; ½c per pound on the former and one cent on the latter. The situation in wire and wire products has been without feature for some time and some mills are feeling about for additional business. It is the general impression that present prices will be maintained for some time. The demand for wire rods however is in excess of the supply and higher prices are not improbable. Wrought iron pipe and boiler tubes are in good demand; many makers of the latter being filled up for from 12 to 18 months ahead. Nominal prices are all that are listed and further advances to these may be expected. Weather conditions and freight embargoes are seriously effecting production and shipping facilities in every direction.

Metals

The general market is featured by a gradual return to more settled conditions, following the firm attitude of Britain in her reply to recent "peace" manoeuvres. Copper has regained some of its recent loss. Tin is stronger as a result of increase marine risks. Spelter is quiet but firm. Lead is scarce and more active.

Copper.—A firmer tone has at last been attained and the strength of the market is reflected in higher prices. This has resulted from the unfaltering attitude of the British Government. The return to higher prices however, is not the result of an active increase in the demand, but owing to the fact that producers are not over anxious to quote or offer metal for sale. This stand has caused holders of resale metal to secure offers at higher prices. Following the progress of events of the past several weeks, it is rumored that negotiations are contemplated for future requirements for the Allied governments, and in anticipation of present conditions continuing the situation will undoubtedly regain much of the strength lost during the recent unsettled period. With the British situation under the control of the authorities, the market at present remains quiet, but the New York situation has steadied under the firm tone and nominal price is now 2c higher than last week; lake being back to a basis of 30c and electrolytic 31c per lb. In spite of the unsettled market conditions that have featured the metal situaion, local dealers have retained their high quotations and present developments would seem to indicate their faith in the market. Lake and electrolytic are steady at 36c and castings at 35c per lb.

Tin.—In the absence of any heavy buying, the market has apparently developed a firmer tone, with advance in price quotations. The cause of this is largely due to the activity recently shown by German raiders on ocean commerce and the increased risk contingent with such developments. Consumers are showing their anxiety over the present conditions, and nervousness marks the trend of the market. While the movements of raiders and shipping knowledge remain uncertain, the market is likely to continue to hold firm, and probably show further strength. London and New York are both higher, the latter quoting 45½c, an advance of 2½c on the week. Dealers here, while reporting a firmer feeling, are maintaining last week's prices of 47c per lb.

Spelter.—This metal continues very quiet, buying being confined to small job lots. The trade is somewhat at a loss to define the uninterested attitude of consumers, as it is generally conceded that many of these are not well covered for early future requirements. The demand for spelter has been correspondingly lower than for copper, and unless orders are being placed without the knowledge of the trade, it is expected that greater activity will develop within the next few weeks. Quotations have declined on the London market, but New York shows an advance of nearly ½c, the current price being 10c per lb. Conditions here are unchanged, with prices firm at 13½c per lb.

Lead.—The dullness that was apparent last week has been shaken off, and the market has added strength to its recent firmness. This is not alone due to altered political conditions, but also to a visible scarcity of available metal. Consumers, however, are cautious regarding their purchases in view of possible developments. New York quotations are very firm, with independents asking 7¾c, an advance of ⅛c over last week. Dealers here continue to quote 10c on a steady market.

Antimony.—The market is quiet, with a firmer undertone, owing to decrease in visible supply. New York is quoting 15c, an advance of ⅝c on the week. Dealers here are asking 16c, this being 1c higher than last week.

Aluminum.—The market is steady, with weakness showing on New York quotations. Prices here are firm at 70c per lb.

Machine Tools and Supplies

Steady activity continues throughout the machine tool industry, but the present demand is confined to small or single lots for specific purposes. Additions to munitions plants has called for new equipment, but bulky orders are now the exception rather than the rule. A feature of the situation is the increased interest that American machine houses are taking in the Canadian field. This is due to the probability that munitions contracts are being rapidly completed in the States, with little prospect of further orders. Many firms that have recently made their final shipments are now offering their entire outfit for sale. The supply situation is still very active, and price advances are still the feature of the market.

Scrap

The market in scrap is a little stronger than last week, but is still inactive. A general advance has affected the New York situation. The dealers here report satisfactory transactions, with prices slightly stronger. Coppers are higher, 20c being asked for light and 24c for heavy and crucible. Machine compositions and turnings are ½c higher, being quoted at 21c and 17c respectively.

Toronto, Ont., Jan. 23.—Further evidence of the importance which is attached to the munitions industry and its development is shown in the decision to establish a steel plant in the Ashbridge's Bay industrial district. This will be distinctly beneficial to Toronto not only under present conditions but also after the war.

The industrial situation is still being affected by transportation difficulties principally by reason of the continued shortage of coal. Although there has been during the past week a heavy movement of coal from Buffalo to Toronto, it has only been sufficient to take care of immediate requirements. The severe weather has added to the difficulties of the situation and a serious shortage of fuel, threatens the city. All classes of freight, particularly less-than-car-lot shipments, are being delayed in transit, causing considerable annoyance to merchants and others.

Steel

An important and interesting development in the steel trade in this district is the steel plant which the Imperial Munitions Board are going to build here. The new plant will add approximately 100,000 tons per annum to this country's steel supply. It is understood that the plant will be operated as a steel foundry and the output will be taken over by the Munitions Board for the duration of the war. This plant is the outcome of the heavy demand for steel for munitions which is steadily increasing in volume and is leaving a comparatively small tonnage for other purposes. As a result of this situation, prices are very firm and continue to have an upward tendency. Prices on iron and steel bars which had been withdrawn, are now higher, iron bars being quoted at 3.90c and steel bars at 4.10c per lb. Cut nails have advanced 50c and are now quoted at $4.50 per 100 lbs. The new discount on plate washers is 10 per cent. as against 20 per cent. formerly. There is no improvement in the plate situation; the demand in the primary market continues enormously heavy, and it is predicted that prices will go higher. Prices of boiler tubes are practically nominal and a further advance is likely in the near future.

There is not much change in the situation as regards black sheets. Production continues to be curtailed on account of the shortage of sheet bars and fuel. Prices are still high and further advances are expected. Prices of galvanized sheets continue firm and are unchanged meantime.

Conditions in the steel trade in the U.S. are quieter but prices continue firm, and on some products have advanced. Steel bars are higher, being quoted at 3.25c Pittsburgh, but plates and small shapes are unchanged at 4.50c and 3.25c, respectively. A heavy demand exists for billets and sheet bars, and prices are higher. Bessemer and open-hearth billets, and open-hearth sheet bars, are now being quoted at $65 a ton Pittsburgh. Transportations difficulties have not improved and the situation is serious.

Pig Iron

The demand for pig iron for making steel has exceeded the capacity of the Canadian furnaces and consequently considerable tonnages of basic iron are being imported from the States. Orders for basic iron have been placed with Chicago and Cleveland furnaces, while 500 tons of Southern foundry iron have also been purchased by Canadian interests for delivery over the last half of this year. Prices on domestic pig irons are still withdrawn, while U.S. prices are unchanged, basic iron at Buffalo furnace being quoted at $35 per ton.

Scrap

There have been no price changes this week, but the market is firmer and there is a strong undercurrent which will no doubt result in higher quotations. While the embargo on scrap iron and steel is still in force, licenses are being issued for the exportation of steel boring and turnings up to the end of the month, and the question of further extension is under consideration. Much satisfaction is felt in the trade over the installation of electric furnaces at the Ashbridge's Bay industrial district as it is understood that large quantities of steel scrap, particularly turnings and borings will be utilized.

Machine Tools

There is little change to note in the situation. Local dealers report business as being fairly active, the principal demand being for single machines for munitions plants which are being called upon to increase production.

Supplies

Prices continue to advance on a number of lines of machine shop supplies owing to the high price of raw materials. Pure Manila rope has advanced 1½c and is now quoted at 27c base. As a result of this, higher prices have been announced on transmission rope and drilling cables, these being now quoted at 35c and 30c base respectively. It will be observed that the differential for these lines has been changed from

4c to 8c. Higher prices on cotton and wool waste have been issued ranging from 1½c to 3c per pound according to grade. A further advance-approximately 5 per cent. has been made on globe, angle and check valves. Gasoline has advanced 1c and is now quoted at 29½c a gallon.

Metals

The metal markets generally are firmer following the reply of the Allies to the German peace proposals. A general opinion in the trade is that peace is actually further off than was thought at the time the proposals were offered. Prices however are unchanged although there are indications that an upward movement may soon start. It is not likely the movement will be very pronounced, although the shrinkage in prices will be delayed.

Copper.—As the market is controlled by the British Government following an order recently issued by the Minister of Munitions, prices hardly represent the situation. They are however, firmer and an advance is probable. Local quotations are nominal at 30c per pound.

Tin.—Quotations are firm but the market is rather unsettled owing to the increased dangers to marine transportation by submarines and raiders. Local prices are unchanged at 47c per pound.

Spelter.—The market is dull, and consumers continue to show lack of interest. Spelter is unchanged at 13½c per pound.

Lead.—The market is firm with an upward tendency. The Trust continues to ask 7.50c New York, but outside interests are quoting higher. Local price is unchanged at 8½c per pound.

Antimony.—The market is strong due to the reduced supply of antimony, but quotations are unchanged and nominal at 18c per pound.

Aluminum.—The market is easier on poor demand, but quotations are unchanged at 68c per pound.

Solders.—The situation in solders has improved and quotations have advanced 1c per pound. Guaranteed is quoted at 29½c and strictly at 27½c per pound.

H.M.C. TORPEDO BOAT "GRILSE"

The Editor,
Canadian Machinery and Manufacturing News,
143-153 University Avenue,
Toronto, Canada.

Dear Sir,—In the December 21st number of your publication, I notice an illustration purporting to be "H.M.C. Torpedo Boat 'Grilse,'" together with an editorial called "The 'Grilse' Near Tragedy." As I purchased the "Grilse," and also served as her commander for about a year, I think an explanation from me is in order.

In the first place, the picture you published of the "Grilse" is not the "Grilse." Of course, I can understand that your article might be justified if the "Grilse" were such a type of ship as your picture shows, because I would

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—H. R. Poussette, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—Acting Trade Commissioner, Lonja del Commercio, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—G. B. Johnson, P. O. Box 109, Yokohoma. Cable address, Canadian.

HOLLAND—Acting Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrivskaya, Ploshch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent. Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 27-28 Pearl Building, East Paradise, Leeds. Cable address, Canadian. F. A. C. Bickerike, Canada Chambers, 36 Spring Gardens, Manchester. Cable address, Cantracom. J. T. Lithgow, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.

SPECIAL TRADE COMMISSIONER—LUMBER

H. R. McMillan, visiting Europe, Africa, Australasia and the Orient.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin, Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum Grubbeged No. 4, Christiania, Norway. Cable address, Sontums.

CANADIAN HIGH COMMISSIONER'S OFFICE

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

not consider the photograph you published as a ship that I would care to go to sea on in the Atlantic in the winter months.

After purchasing the "Grilse," and before she was used by the Department of the Naval Service and altered for war purposes into a destroyer, a report was made by a man who had charge of building British destroyers for a great many years, whose report I would like to quote as follows:

"As requested, I have recently carried out a survey of the hull structure of H.M.C.S. 'Grilse,' and find this vessel similar in scantling to the early thirty-knot destroyers of the British Navy, but the details of the structural design are more in accord with the latest destroyer practice, and give the vessel more strength than in the old thirty-knotters.

"There are no indications that the vessel is in any way strained, or likely to be strained, provided she is navigated with the usual care necessary in all vessels of this class, none of which will, or are expected to, stand hard driving in bad weather."

I herewith enclose a photograph taken of the "Grilse," from which you will see that there is not the slightest similarity between the "Grilse" and the photograph you published, and I may further state that the "Grilse" is over two hundred feet long, not 175 feet, as has been stated, and constructed of the finest high tensile steel, and was not built by Thorneycroft, also as has been stated, but by Yarrows, in England.

Yours truly,

(Signed) J. K. L. Ross.

A FUEL OIL INSTALLATION.

by A. F. Menzies

THE reference to a fuel oil installation in a recent issue of one of your journals, prompts me to give the following description of a mechanical atomisation system installed in connection with a pair of Scotch type marine boilers, and which gave perfect satisfaction. As the job was afloat and in salt water it was considered out of the question to use a steam atomisation system, even though it would have been less expensive to install. The oil was carried in the fore peak tank and a 4 in. suction pipe led from its after bulkhead to the stokehold. On account of the viscosity of the oil, large suction pipes are necessary in order to reduce the velocity and consequently the friction. The oil was pumped by two 3½ in. x 2½ in. x 4 in. steam driven duplex pumps, which, on account of the deleterious action of the oil on rubber, etc., were specified to be fitted with brass rings and valves in the oil end, and to be packed with asbestos. Immediately in front of where the suction pipe entered the pumps, a twin suction strainer was installed, arranged to be cleaned out while steaming.

Steam Supply to Pumps

The steam supply to the pumps was regulated by the oil pressure in the discharge line, the regulating valves being set to the desired pressure, which is usually found by trial. In this particular instance, a pressure of 90 lbs. per sq. in. was found suitable, when using a No. 3 Dahl tip. On leaving the pumps, the oil was piped to a pair of live steam heaters, consisting of a cast iron shell in which a coil of pipe was placed. The oil passed inside the pipe, while steam was admitted to the shell, the temperature of the oil being raised to from 225 to 250 degs. F. A high pressure steam thermometer was installed in the heater outlet in order that the temperature could be ascertained. In a by pass between the pumps and the heater, a Worthington oil meter was installed. To remove any fine particles of grit or pipe scale from the oil, a pair of discharge strainers were installed between the heaters and the furnaces, and as the oil is of much lower viscosity when heated, a strainer of fine mesh can be used on the discharge line.

The header from which the burners were fed was led across the front of the boilers below the furnaces, branches being taken to each burner. The end of the header was connected to the suction pipe in order that a circulation of oil could be obtained on starting up, thus providing heated oil at the burners. The burners themselves, one for each furnace, consisted of a piece of pipe with a special tip at one end having spiral passages leading to a circular hole in the centre.

Fire Regulation

The size of the fire could be regulated by varying the pressure of the oil. If the desired results could not be obtained within the suitable range of pressures, it was a very simple matter to subsititute a tip with a larger or smaller hole as the case required. With the before-mentioned pressure, a tip with a 1-32 in. hole gave very good results. The furnaces were 37 inches in diameter. The outer end of the burner had a special union connection to the oil pipe branch, and could be removed by the slackening of one set screw. If a burner did not work satisfactorily or got choked up, it was the work of less than half a minute to remove it and substitute a spare one. Surrounding the burner tip was a hollow cast iron cone with the apex pointing to the furnace front. The cone was carried on a pipe through which the burner passed and was made conveniently adjustable, in and out. Its correct adjustment was an important factor in smokeless combustion.

The fire bars, bearers and all brick work, were removed from the furnace and new fronts were installed. The fronts were ⅜ in. plate and had hinged air doors above and below the burners. Commencing at the front, the furnace was lined with firebrick for about three feet, in order to give protection from the intense heat. A considerable reduction in the consumption of fuel was obtained by the use of spiral retarders in the tubes. It will be noted in this installation that all important items, pumps, strainers and heaters, were installed in duplicate, the object to avoid a shut down. If this precaution were not considered necessary, a single pump and heater could be used. Strainers should, however, be duplicated. The apparatus for this installation was secured to the stokehold bulkhead, and was so connected up with unions that any piece could be undone and removed for convenient overhaul.

Oil Burning Regulations

Some of the more important regulations which have to be observed in connection with an oil burning system coming under the control of the Canadian Steamboat Inspection are as follows: Storage tanks must be absolutely tight and constructed of not less than ¼ in. plate. The stop valve on the tank end of the suction pipe must be located inside the tank, and the spindle extended through a stuffing-box on the tank top. The idea of this is to prevent leakage from the valve spindle draining into the bilges. Proper ventilation must be provided for the tank. The exhaust steam from the oil heater must not be piped to the condenser; but must be drained overboard or into the bilges.

In any oil installation, ground joint union and regrinding valves are an absolute necessity. After installation and before oil is admitted to the pipes they should have all dirt, pipe scale, etc., blown out with compressed air or steam. It is a comparatively easy matter to clean the pipes when first put up, but it is a different story after they have been filled with sticky oil.

The Economy Feature

As regards the economy of using liquid instead of solid fuel, this simply resolves itself into a question of their relative costs. On the Pacific Coast, where coal contains between 12,000 and 13,000 B.t.u. per lb., and the grade of oil sold for fuel purposes runs from 19,000 to 20,000 B.t.u. a ton of coal is usually regarded as equivalent to from 3½ to 4 barrels of oil. Oil can be wastefully fired just as easily as coal, if not, more so, as there is less labour involved for the fireman if he is economical with his coal. There is the saving of labour handling to be figured to the advantage of liquid fuel. In this particular installation no exact comparison was possible.

All the special apparatus used on this installation was manufactured by the Union Iron Works, of San Francisco, Cal., under the Dahl patents. The work of installation was carried out by the Wallace Ship Yards Ltd. of North Vancouver, B.C. Lunkenheimer regrinding valves, and Dart unions were used throughout.

A Chain of Evidence is the title of publication No. 15, issued by the Morse Chain Co., Ithaca, N.Y. This bulletin, although bearing a sub-title, "Small Power Drives," is not confined to small drives, but includes drives up to 100 h.p.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Wingham, Ont.—The Western Foundry Co. contemplates an addition to its foundry here.

New Glasgow, N.S.—The Nova Scotia Steel & Coal Co. are making considerable extensions to their plant.

Toronto, Ont.—Work has started on an addition to the factory of the Chapman Double Ball Bearing Co. here to cost $17,500.

Hamilton, Ont.—The Standard Underground Cable Co. has commenced the erection of an addition to its plant to cost $12,000.

Calgary, Alta.—The Alberta Farmers' Co-operative Elevator Co., is in the market for mechanical equipment for new elevators which will be constructed.

St. Mary's, Ont.—The Detroit Chassis Co., of Detroit, Mich., have written the City Council regarding establishing a factory here for making motor cars, trucks, etc.

St. John's, Que.—The Dominion Crucible, Co., a subsidiary of the Dominion Bridge Co., Montreal, will have work commenced at an early date on the erection of a plant here.

Cobalt, Ont.—The management of the Porcupine Premier Mine have recently intalled a new compressor plant and towards the end of this year may install a small Hardinge mill.

Trenton, Ont.—Good progress is being made on the new plant for the Imperial Munitions Board by the contractors, the Gaylord Engineering & Construction Co., and the Pratt Engineering Co.

Amherst, N.S.—A fire, with a monetary loss of about $30,000, occurred at the International Engineering Works on January 21. The fire broke out at the west end of the boiler shop, a building 200 feet by 150. The loss is covered by insurance.

Toronto, Ont.—The site selected by the Imperial Munitions Board for the new steel plant at the Harbor Commissioners Industrial Area, contains sixty acres. An option has been secured on thirty acres to the east with a view to ultimate enlargement. There will be five buildings, one of which will be 300 feet long and 125 feet wide, with an interior clearance of 40 feet in which traveling cranes will be operated. The buildings will be of steel construction and the cost will be well over $2,000,000 and may run as high as $3,000,000. There will be ten six-ton furnaces, 25-cycle Heroult furnaces, requiring 2,000 h.p. each to operate, or a total of 20,000 horse power. It is understood that the furnaces have been purchased through the U.S. Steel Corporation. The contract price is said to be $500,000.

Halifax, N.S.—It is understood that the Nova Scotia Steel & Coal Co. will manufacture 7,000 car axles for the Russian cars now building at the shops of the Eastern Car Co., a subsidiary of the Nova Scotia Steel Co. This action follows the unsuccessful negotiation for this material in the United States during the last two weeks. It is possible that the 24,000 car wheels needed for the same construction may also be made at the shops of the Nova Scotia Steel Co.

Victoria, B.C.—Work on additions to the Ladysmith smelter, formerly owned by the Tyee Copper Co., has been commenced under the direction of W. J. Watson, manager. It is proposed to expend approximately $100,000, the chief improvement being the installation of a converter which will permit of the output of copper matte whereas, hitherto, the plant could produce only blister copper. The new owners have secured additional land and will increase the present daily capacity of 600 tons to about double that amount. Provided machinery now on order is received without undue delay, the plant will be ready for operation in about three months.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

MUNICIPAL

St. Mary's, Ont.—The City Council contemplate installing a sewage disposal plant.

Brantford, Ont.—The Township Council are negotiating for the installation of Hydro-Electric power in the township.

Chatham, Ont.—$45,000 for extensions to the local Hydro-Electric system and $16,000 for extension of water mains to westerly limits of the city, passed by council, January 8.

Hamilton, Ont.—James Bain, engineer at the Beach Pumping Station, has suggestion that a turbine and a 10,000,000-gallon pump be installed at a probable cost of $50,000 to tide over the situation until times become normal again. He was instructed to prepare plans and secure data in the matter.

Toronto, Ont.—The York Township Council will call tenders shortly for the supply of material and construction of water mains in sections A and B of the township's plan. The cost is estimated at $320,000.

ELECTRICAL

Toronto, Ont.—The Hydro-Electric Commission have leased additional land at the Garrison Commons and will extend their distribution plant there.

Windsor, Ont.—The Hydro-Electric Commission is asking the Council of Windsor to issue $50,000 worth of debentures for improvements and extensions.

GENERAL

Grimsby, Ont.—The Metal Craft Mfg. Co., propose building a factory here to manufacture steel goods.

Winnipeg, Man.—Fire, recently destroyed the plant of the F. J. Welwood Mfg. Co., at Elmwood. The loss is estimated at $10,000.

Tillsonburg, Ont.—D. Trevail & Son, South Middleton, whose cheese box factory was totally destroyed by fire in the fall, have rebuilt, and are again about ready for operations.

Toronto, Ont.—Benjamin Moore, Ltd., paint manufacturers, have purchased a site adjoining their plant at West Toronto, and will build a factory, 90 x 132 feet. They have just completed a large addition, and will shortly start construction of a varnish plant.

Tillsonburg, Ont.—The Huntley Mfg. Co., of Silver Creek, N.Y., who recently purchased the plant of the Tillsonburg Electric Car & Coach Co., by March 1 will be equipped to start operations. They will manufacture fifty different lines of milling and canning factory machinery. In the spring a large addition will be constructed with railway sidings.

BUILDINGS

Toronto, Ont.—Gowans, Kent & Co., have prepared plans for a six storey office building to be erected on Front street a short distance east of Bay.

Toronto, Ont.—The Toronto Board of Harbor Commissioners has prepared plans for a large office building to be erected on the water front at the foot of Bay street. It will be five storeys high and cost $250,000.

RAILWAYS AND BRIDGES

Montreal, Que.—Contracts have been let for the new C. N. R. station at the corner of Lagauchetiere and St. Monique Streets. Norcross Bros. will erect the building, which will be some 100 feet square. It will serve as a temporary station pending the terection of the larger permanent structure. Angus Sinclair was given the contract for the excavation work in connection with the large permanent station. The contract will involve the removal of some 280,000 cubic yards of earth, stone, etc.

MARINE

Victoria, B.C.—The City Council have endorsed the petition put out by the Esquimault Graving Dock Committee, calling on the Dominion Government to take action for the early completion of the graving dock at Esquimault for which property was purchased at Lang's Cove in 1914. It is well known that the dock completed in 1887 has for a long time been insufficient to take care of modern shipping. This fact was admitted by the Dominion Government as far back as 1912, when steps were taken to enlarge the present dock or purchase a new site whereon a dock could be built large enough for all modern requirements.

TENDERS

Winnipeg, Man.—Tenders will be called until February 12, 1917, for works required for the completion of the new Parliament Buildings, which include the following: Heating and ventilating, electric conduit and wiring. Thos. H. Johnson, Minister of Public Works, Winnipeg.

Winnipeg, Man.—Tenders will be received by R. D. Waugh, chairman of Commissioners, Greater Winnipeg Water District, up to February 5, 1917, for the supply of indicating and recording apparatus for two Venturi meters. Specifications may be obtained at the office of the district, 501 Tribune Building.

Toronto, Ont.—Tenders will be received, addressed to the chairman, Board of Control, City Hall, Toronto, up to January 30, for the installation of a 40-million Imperial gallon centrifugal sewage pump at the main sewage pumping station, Toronto. Specifications and forms of tender may be obtained at the Works Department, Room 6, City Hall.

London, Ont.—Tenders will be received up to January 29, 1917, for the supply and delivery of: (a) Special railroad track work, consisting of five (5) whole and two half crossings of manganese steel construction; (b) two horse-drawn road oil distributers. Specifications, form of tender, etc., can be seen at the office of H. A. Brazier, city engineer.

Ottawa, Ont.—Tenders will be received at this office until February 12, for the supply of: Brooms and brushes, chain, coal, hardware, hose, oils and greases, packing, paint and paint oils, Manila rope, wire rope and steam pipe, valves and fittings, for the requirements of the departmental dredging plant in Ontario and Quebec during the fiscal year 1917-18. These forms of tender can be obtained at the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

INCORPORATIONS

The Metal Craft Co. has been incorporated at Toronto, with a capital of $40,000, to manufacture all kinds of sheet metal, furniture, etc., at Grimsby, Ont. The provisional directors are: Frank P. Macklem, Hugh D. Walker and E. B. Darley, all of Toronto.

The New Brunswick Sulphate Fibre Co. has been incorporated at Ottawa, with a capital of $200,000, to carry on a lumbering business and manufacture wood alcohol and calcium carbide, etc., with head office at Montreal. The incorporators are: Gordon W. MacDougall, L. Macfarlane, and W. B. Scott, all of Montreal.

St. Lawrence Smelting & Refining Co. have been incorporated at Ottawa, with a capital of $100,000, to carry on the business of smelting and refining minerals of all kinds, at Kingston, Ont. The incorporators are: F. H. Markey, Waldo W. Skinner and W. G. Pugsley, all of Montreal.

PERSONAL

Hon. Col. Frederic Nicholls of Toronto, has been appointed to the Canadian Senate. Col. Nicholls is president and general manager of the Canadian General Electric Co., and Candian Allis-Chalmers Ltd. He is a director of the Canadian Northern Railway and also of a number of industrial concerns.

TRADE GOSSIP

The Hoyt Metal Co., Eastern Avenue, Toronto, have installed a plant for making high-grade wire solder, lead pipe and "Came" lead.

Zephirin Hebert, vice-president of the Montreal Board of Trade for the past year, has been elected president by acclamation. Mr. Hebert is the first French-Canadian president of the Montreal Board of Trade.

The Daylight & Ventilation Co., Stair Bldg., Toronto, are completing the installation of straight push sash operators for controlling 8,000 feet of sash at the Dominion Government Arsenal at Lindsay, Ont. They have also booked an order for similar equipment for the International Nickel Co. new plant at Port Colborne, Ont. This installation will control 12,000 feet of sash.

Industrial Utilization of Straw.—Lord Shaughnessy has authorized a well-known chemist in London, Eng., to undertake a comprehensive research with regard to possible use of the straw of wheat, oats, barley and rye, with a view to its industrial utilization. In Western Canada, it has been the custom to burn this straw as refuse.

To Develop British Trade.—C. Hamilton Wickes, the British Government Trade Commissioner of Canada and Newfoundland, is shortly leaving for England. While there he will visit the principal industrial centres throughout the United Kingdom, on the subject of British trade and its future development in Canada.

The Canadian H. W. Johns-Manville Co. held a convention of salesmen and managers of various departments at the King Edward Hotel, Toronto, during the week of January 15 to 20. Over thirty-eight salesmen from all parts of Canada were present at the convention, which was presided over by W. M. Hiller, general manager of the Toronto branch.

British Firm Winner.—Advices from Washington, D.C., state that contracts for armor piercing navy projectiles of the 14 and 16-inch type, totalling $3,141,000, have been awarded by Secretary Daniels to the Hadfields, Limited, the English munition company. Bids from American firms were more than $200 a shell in excess of that submitted by Hadfields, and deliveries covered over twice the length of time.

British Export Restrictions.—The Department of Trade and Commerce, Ottawa has issued a form of affidavit to be used in connection with exporting of goods from the Old Country to Canada as required by the Ministry of Munitions. The affidavit is for information required to be filed by actual users with the Department of Trade and Commerce in connection with all applications to receive shipments from the United Kingdom of goods upon the British Export Restriction List.

The Spence Co. have opened an office in the Birks Building, Montreal, and will handle an extensive line of steel products, such as bars and shapes, reinforcing bars, tool steel, etc. The company are direct distributing agents of various mills in the States, and have made favorable arrangements for the delivery of goods. The Spence Co. will also supply the Canadian market with ingot metals, machinery, beltings, chemicals and ores. The steel department will be under the supervision and management of Lionel L. Phillips.

Bauxite in British Guiana.—In the past year there has been considerable excitement in Dutch Guiana due to the discovery of large deposits of bauxite on the Surinam River, some hours' journey from Paramaribo, and also on the Demarara River in British Guinana. The Aluminum Co. of America is already developing deposits and arranging for transportation to the United States coast and gulf ports. One ship has already been purchased and will be taken to the

See Page 66

coast at the opening of navigation this year. Alterations to fit the vessel for the trade are under way.

Haileybury School of Mines.—The new engineering laboratories of the Haileybury School of Mines, at Haileybury, Ont., are nearing completion, and the school is now procuring their machinery and equipment. The laboratories will comprise a complete machine shop, carpenter shop, blacksmith shop, small size contractor, cyanide mill, flotation plant, and assay office, and will contain most of the machines usually met with in these lines. The school has the co-operation of the mines of the Cobalt district, and of manufacturers of mining and other machinery, and is always pleased to make arrangements with manufacturers and have their machinery represented in the school.

Blast Furnaces in France.—The number of blast furnaces in France in unoccupied territory is now forty-eight in blast, according to *L'Usine*, Paris, with eight ready to be blown in as soon as coke can be obtained. These furnaces are situated on the coast at Calais, Outreau, Panillac, Trignac, and Le Bouceau; in central and southern France at Le Creusot, Chasse, Givors, Firminy, Alais, Montlucon, Decazeville, Furnel, Saut-du-Tarn, Tarascon-sur-Ariège and Ris. The furnaces use both French and foreign ore, and their present output is only from 110,000 to 120,000 tons per month. The basin of Nancy furnishes over 50,000 tons of ore per month, while the plants on the coast get ore mostly from Bilbao, Spain.

Strikes During December. — The monthly statement of the Department of Labor for last month, issued on January 15, indicates that the number of strikes beginning in December was three as compared with fourteen in November. There were altogether thirteen strikes in existence during December, ten of which began before the first of the month. In the three new strikes of the month, three firms and 627 employees were involved, while in the ten strikes commencing before December, 29 firms and 715 employees were involved, making a total of 32 firms and 1,342 employees involved in the 16 strikes in existence during December. Settlements were effected in the case of four of these disputes, leaving nine unsettled strikes in existence at the end of December. Coal miners were affected by one, and clothing workers by two of the December strikes.

CATALOGUES

Stellite.—Two bulletins have been issued by the Deloro Smelting & Refining Co., Toronto. One of these bulletins contains directions for using "Stellite" tools, while the other deals with "Stellite" as a money-saver. In the latter bulletin, which was written by Elwood Haynes, the subject is treated from an efficiency viewpoint.

File Sharpener.—Bulletin O describes the "Buckeye" file sharpening machine made by the McLeod Co., Cincinnati, Ohio. The principal features of this machine and its method of operation are described at length, accompanied by illustrations.

The International Malleable Iron Co., Guelph, Ont., have issued a new catalogue. J, showing a large variety of cast iron and malleable fittings which they manufacture. A very complete line of fittings is illustrated accompanied by lists covering the various sizes. The concluding pages of this catalogue deal principally with cast iron sectional and other types of boiler, heating systems and waterworks supplies.

Optical Pyrometer. — Barnes-Morris, London, England, have recently issued a catalogue dealing with the "Wedge" optical pyrometer. A full description is given of the instrument covering its salient features and method of operation. The field of application is dealt with in connection with various processes of heat treatment, such as annealing and hardening, and also in connection with different industries, particularly glass manufacture.

High Speed Drills, Reamers, Etc.—Catalog No. 15 deals with an interesting line of Celfor high-speed twist drills, reamers, countersinks, chucks, sockets, flue cutters, etc. The catalogue is fully illustrated and contains prices and particulars of each size of tool. The concluding pages of the catalogue contain a telegraphic code, speed and feed table for Celfor drills, and a table of decimal equivalents. Copies of this catalogue may be obtained from the Clark Equipment Co., Buchanan, Mich.

Storage Battery Trucks for industrial plants is the title of Bulletin No. 200, recently issued by the Jeffrey Mfg. Co., Columbus, Ohio. The bulletin contains illustrations, specifications and descriptions of various types of storage battery trucks for industrial plants, warehouses, factories, foundries, etc. The illustrations show various types of trucks working under different conditions featuring their wide range of operation. Copies of this bulletin can be obtained by writing to the company's Canadian office in the Power Building, Montreal.

Heat Treatment.—Bulletin 866—A, entitled "Apparatus for the Location of Thermal Transformation Points" which has recently been published, describes and illustrates apparatus developed by the Leeds & Northrup Co., Philadelphia, Pa. The apparatus is fully described, as is also the method of determining the critical or transformation temperature on which certain physical and chemical changes take place when the metal is heated and cooled. An interesting series of charts is shown exhibiting the transformation points in samples of carbon steel containing various percentages of carbon. The catalogue contains considerable interesting matter on heat treatment of steel and other metals of particular value to designers of automobile and other classes of machinery, where the requirements are exceptionally stringent.

BOOK REVIEWS

Railway Regulation.—A recent publication of LaSalle Extension University which has become of special interest to the public from recent developments in the transportation world is Railway Regulation, by Professor L. Leo. Sharfman, of the University of Michigan. This is the only recent and authoritative summing up of the whole subject and should be read by all railroad men.

Specific Gravity Studies of Illinois Coals.—Experiments conducted at the Engineering Experiment Station of the University of Illinois have established a relationship between the ash content of bituminous coal and its specific gravity which makes possible rapid estimation of the ash and moisture content. These tests have also shown that a knowledge of the specific gravity of coal simplifies the problems of estimating tonnages underground and in storage, and of determining the adaptability of coal to treatment by the washing process. The experiments were made by M. L. Nebel and the results are published as Bulletin No. 89 of the Engineering Experiment Station, copies of which may be secured upon request from W. F. M. Goss, Director, Urbana, Ill.

Investigation of Coals in Canada.—The Department of Mines, Ottawa, has issued bulletin No. 338 supplementing report No. 83 under the title of "Investigation of the Coals of Canada with reference to their economic qualities. It will be remembered that the original investigation was conducted at McGill Universtiy, Montreal. This bulletin No. 338 deals with the "Weathering of Coal" and covers an extended study of oxidation of coal as a part of the original investigation referred to above. The subject is an important one in Canada where climatic conditions necessitate the storage of large amounts of bituminous coal at central distribution points. The bulletin contains much interesting data obtained from a series of laboratory experiments on the oxidation of coal at low temperatures and also studies of coal storage both at the mines, in Montreal, and also in other cities. The bulletin was compiled by Dr. T. B. Porter and can be obtained from the Government Printing Bureau, Ottawa.

RUSSIAN ASBESTOS INDUSTRY

ASBESTOS is found in insignificant quantities in the Caucasus and in Siberia, but about 99 per cent. of the Russian output is mined in the Ural mountains. Some of the best asbestos mined in the Urals is produced at mines 60 miles northwest of Ekaterinburg, in a zone of serpentine rocks, which extends about 6 miles and is about 1,400 yards broad. The quality of this asbestos is believed to be as high as that of

Canada and Piedmont. The veins are directly broken off either by hand or by a hard hammer. The operation of mining asbestos in the Urals is of a primitive character, but in some cases the production is being made more systematic.

Ekaterinburg Asbestos Mines and Their Output

The most important of the Ekaterinburg asbestos mines are the Vosnesensky Zoe-Anonsky asbestos mines, situated nineteen miles from the station of Bazhenof, on the Perm-Tyumen railway. A third of the asbestos produced in the Urals is obtained here and all the asbestos produced was dispatched abroad, untreated, through Reval. The Shchongy asbestos mines in the village of Mostovsky produce less than the above mines, all the asbestos produced being worked up in the factory, where sheeting, bands, twine, insertion, thread, etc., are made. The Govorikhinsky asbestos mines lie in a line with the Voznesensky mines and yielded 3,183 tons of asbestos in 1911. Six miles from the Meivo-Shaitansk factory of the Alapievsky Mining Works are the Kirtanovsky asbestos mines, with a sorting factory where 2,000 tons of asbestos can be sorted per annum. Close to these mines are the mines of the Russo-Italian Asbestos Co., the N. V. Mikhanov Co., the "Uralite Co.," etc. The following figures show the output of the Ural (Ekaterinburg) asbestos from 1906 to 1913: 1906, 8,001 short tons; 1907, 8,743 short tons; 1908, 10,694 short tons; 1909, 13,129 short tons; 1910, 10,936 short tons; 1911, 15,872 short tons; 1912, 16,584 short tons; 1913, 16,661 short tons. Practically the whole of the output was exported via Riga.

Other Mines of the Urals

North of Ekaterinburg asbestos is found in the Bogolsof mining area, in the Kortiakovsky mines (where the vein is about 2 feet thick), near the Alapievsky works, the Venansky works, on the river Uktussa, near the Beresovka works, etc. In the southern Urals asbestos deposits are found at the Khristogor and Petropavlovsky ore mines, near the Miask works on the river Krasnacht, in the Gavrilof copper mines (of excellent quality), in the Atliansky gold placer, near the river Imian Yurt (in talcous schist); there are veins of asbestos near the Kisnikaievsky copper mine at the foot of the Naralinsky hills; also amongst the serpentine of the river Kara, near the Kachinsky factory, and along the river Guberle, near the fort of that name. The best mineral is considered to be that of the Asbestovoy hill, on the river Sissert, and the asbestos deposits of the Shelkovoy hill, on the land of the Nizhni-Tagil works, between the Shouralinsky and the Teploy hills. To the south of the Ural range of hills in the Government of Orenburg, there are some exploited asbestos mines—the Natalievsky in the Upper Ural district, the Isserganskv in the Orsk district, and the Kholmisty in the Troitzk district.

The following companies have joined the syndicate of Ural asbestos producers: (1) Voznesensky asbestos mines, with an annual output of 3,106 tons; (2) Yakovley Succs., with an annual output of 1,806 tons; (3) Poklevsky-Kozell Succs., with an annual output of 5,416 tons; (4) Korievo asbestos mines, with an annual output of 2,709 tons; (5) Girard de Soukanton, with an annual output of 3,611 tons; (6) Russo-Italian Asbestos Mining Co., with an annual output of 1,806 tons; total, 18,454 tons.

Exports of Asbestos

It is stated that all the companies operating in this district are privately owned and managed. The present transport facilities from the mines are confined to the single-track line of the Perm Railroad, connecting with the Northern Railroad to Petrograd. Asbestos is now on the embargo list, but application for special export licenses may be made to the Department of Customs, Petrograd. Even should such license be granted, the great congestion on all the railroads and in all the parts of Russia makes transportation extremely difficult. Under a recent order of the Russian Government no goods other than those approved by the Government as being specially imported for military purposes are allowed to enter Russia by any of the White Sea ports. This, of course, reduces the amount of available tonnage, as fewer ships will arrive than formerly.

According to official statistics, the exports of asbestos from Russia for the last seven years were as follows:—1909, 9,160 short tons; 1910, 9,689 short tons; 1911, 13,524 short tons; 1912, 15,547 short tons; 1913, 13,669 short tons; 1914, 8,577 short tons; 1915, 975 short tons. These exports, before the war, went to Germany, Austria, the United Kingdom, Belgium, and the Netherlands.

Asbestos in the Caucasus and Siberia

Asbestos is produced in the Caucasus in an insignificant quantity in the Sharopon district of the Kutais Government at the Vzhinevi asbestos mines. In the same Government of Kutais asbestos is known to exist far from the deposits already named to the north-west, in the Lechgoumsky district in the Savanetsky police circuit. It is also found in the extreme south-eastern corner of the Caucasus, not far from the Persian frontier, 12 miles from the town of Shusha.

In Siberia, asbestos is exploited only in the Government of Irkutsk in the Angar district at the Angar asbestos mines. In the Government of Yenissei there are asbestos mines on the left bank of the River Kamuisht, near the Saksar and the Ak-kay hills, near Bishtak hill, at a distance of 25 miles from the village of Askeisk, and on the River Karagan, on the boundary of the Mausky and the Servievsky gold placers. In the Tomsk Government it is found in the system of the River Katum, in the Semirechensk territory, on the northern slope of the Dzhigla range, in the Dzhan-Arychsky district, and in the Transbaikal province, in the serpentine of the Klinchinsky ore mine, near the Shilkinsky factory, and in the neighborhood of the tin mines of the Nerchinsk circuit.

On the Mongol-Dabansky gold placers (now worked out), which belong to the Crown, very rich asbestos and mica mines have been discovered. The Mongol-Dabansky gold placers are situated on the River Mongol-Daban, which falls into the River Didi, a tributary of the River Oka. The new mines lie 75 miles from the station Zima, on the Trans-Siberian Railway.—U. S. Commerce Report.

THE TRANSPORTATION OUTLOOK

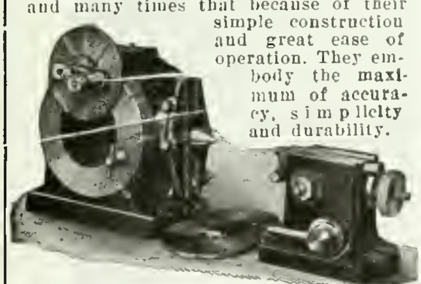
THE Canadian Bank of Commerce, in its monthly commercial letter for January, says:—"For the time being the outlook for all classes of transportation companies is, in respect of volume of business, very satisfactory. The drawbacks being encountered are lack of labor and rolling stock, and, in the case of water-borne traffic, the shortage of tonnage. The gross earnings of the railroads are higher than those of last year or of any previous year. Complaints of delays in shipping and of actual car shortage continue to be made, an indication of the activity of general business as compared with former years.

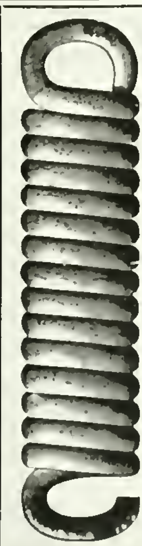
"In the case of lake shipping there is little doubt but that there will be for some years to come abundant employment for a larger tonnage than is at present in service. British registered steel tonnage on the Great Lakes is now 218,019 tons, as compared with 286,121 tons at the close of the season of 1915. The tonnage of the new vessels added to the lake service during the year amounted to 12,218, and that of the vessels purchased from the United States and added to Brtish registry to 15,349 tons. The decline is due to the transfer to ocean service of 50 vessels aggregating 95,669 tons.

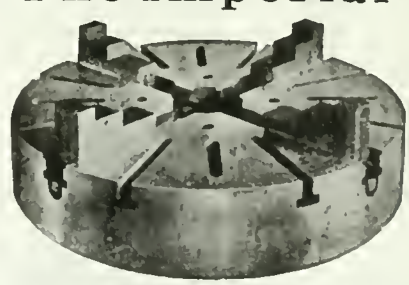
"This decline in tonnage is serious in view of the expanding volume of lake traffic, and under the circumstances it is reasonable to assume that Canadian shipbuilders have before them a period of unusual activity. A large proportion of the total lake freight consists of iron ore, and the carriage charges per ton at present are $1.25, as compared with the normal rate of 50 cents, a marked indication of the general increase in the cost of transportation."

TRADE OF THE DOMINION

A CANADIAN trade total of $1,700,563,269 for the nine months ending with the opening of the new year is shown in the monthly statement issued on Jan. 22, by Hon. Dr. Reid, Minister of Customs. For the corresponding months of 1915 the total Canadian trade was $1,012,486,000. The statement shows continued growth in the export trade of the Dominion. The total exports for the nine months ended December 31 last of Canadian products were $861,629,000, as against $511,534,000 for the corresponding period of the previous year. Of







the exports, domestic manufactured articles lead with $317,841,000 for the nine months, with agricultural products a close second with $317,451,000. The figures for the same period of 1915 were, manufactures $119,399,000, and agriculture $202,506,000.

The exports of animal products also show a substantial increase for the nine months, with $93,586,000 as against $78,-559,000; products of the mine, $63,725,-000 as against $49,034,000; fisheries, $18,075,000 against $16,103,000, and the forest $46,138,000 against $42,184,000.

The imports, exclusive of coin and bullion, for the past nine months were $602,866,000, made up of $330,791,000 dutiable goods, and $272,075,000 free goods. The imports for the same period of 1915 were $197,950,000 dutiable goods, and $145,972,000 free goods, a total of $343,923,000. Duty collected was $106,378,000 as against $71,305,000.

For the month of December last the exports exclusive of coin and bullion were were $130,037,000, and the imports $68,014,000. For December, 1915, the exports were $92,171,000, and the imports $45,690,000. The increase in exports over imports for the nine months, exclusive of coin and bullion was $258,-763,000.

FUTURE TRADE INFLUENCES IN SOUTH AMERICA

THE possibilities of Canadian trade expansion in the future with South American countries is great enough to demand present attention where it is possible to give it, and in view of the important British interests existing there, the opportunity for Canadian business would seem to be already waiting. The fact remains, however, that in Brazil especially, German influence has been particularly active for many years, and the possibilities of British influence being discounted under present conditions was referred to by Miss Edith Browne, F.R.G.S., in a recent lecture at the Royal Colonial Institute on "Possibilities for British Trade in South America after the War"; her remarks applying with considerable force to future efforts on the part of our manufacturers in this country.

Referring to statistics, they were not always easy of assimilation, besides having a limit to their reliability; however, it might be stated, by way of illustration, that Brazil alone, is as big as the whole of the United States without Alaska. All the chief South American republics have recently made great progress and their purchasing power has also increased enormously. It was desirable, however, to remember that the railways and harbours, which had been prime factors in the development of the country, were due to British enterprise, the result to which had been warm friendship between the citizens and the British.

INDEX TO ADVERTISERS

MAIN BUILDING OF THE UNIVERSITY OF TORONTO, NORTH OF AND FACING THE CAMPUS.

Engineering Laboratories of the University of Toronto

By Robert W. Angus, B.A. Sc.*

The growing recognition of the part played by technical education in national development imparts more than passing interest to the instruction plant by means of which the rising and future generations of this country's engineers are receiving knowledge. A study of the equipment described herewith, should convince even the casual critic that the requirements of engineering education have been recognized and met in a capable manner with a full breadth of vision, a desirable consummation in view of future world trade developments.

THE first engineering laboratory in Toronto was formally opened on February 24th, 1892, in the School of Practical Science, which is now the Engineering Building of the Faculty of Applied Science and Engineering of the University of Toronto. This laboratory consisted of three departments: First the department for testing materials of construction. Second, the department for investigating the principles governing the application of power, which department included the steam laboratory, the hydraulic laboratory and the electrical laboratory. The third department was an astronomical and geodetic laboratory.

In the steam power department there were two boilers, the larger of 50 h.p. capacity, a 50 h.p. Brown engine with condensers and pumps, and a machine for measuring journal friction and for testing lubricants.

The hydraulic division contained a three-throw pump driven from the Brown engine, a large impulse wheel, and two large tanks for orifice and weir experiments.

Initial Equipment

This equipment served very well at the beginning; there were not many students and thus a large number of pieces of apparatus was not necessary, and the apparatus actually installed was so well selected and suited the purpose so well that much valuable instruction was given on the machines mentioned.

As the work expanded and the number of students increased, small additions were made, but up to the time the writer was appointed demonstrator in this work in 1898, the only additions were two reaction turbines, neither of which was set up for operation, and a crude type of centrifugal pump, together with tanks for calibrating the orifices and weirs already mentioned.

During the past decade great advances have been made in the development of power, more especially in Canada, where we have been appreciating to some extent the value of our water powers. The gas engine has also been brought to a high state of perfection and suction gas has presented such great possibilities as to make it an important source of power.

Further, the work of the Engineering Faculty has been recognized by the people of the province in such a way that the attendance has increased by leaps and bounds.

For these and other reasons it has been necessary to increase steadily the equipment of the power department to illustrate the modern methods and also to provide sufficient apparatus for the increased number of students.

As the number of pieces of apparatus increased the available space became more and more crowded until during the last few years it has been difficult to carry on the work successfully. The steam laboratory had been placed in a comparatively low basement and the moisture and heat produced by the steam made the working conditions very bad.

After careful examination of the whole question, the Board of Governors of the University decided in June, 1908, upon the erection of a new building to accommodate the laboratories for steam, gas and hydraulic work and also for all general mechanical engineering, and the building described in this article is the result.

The money appropriated for the building as erected was between \$85,000 and \$90,000 and for new equipment approximately \$22,000, although most of the apparatus which had been installed in the old laboratory has been moved in, so that the total value of apparatus and equipment in the new building would considerably exceed the \$22,000 mentioned above.

New Laboratory

The building about to be described contains the laboratory for steam and gas engines, steam boilers, refrigerating machinery, belt and oil testing, and other similar work, and also that for hydraulic work of various kinds. It is built of white brick with white stone trimmings.

*Professor of Mechanical Engineering.

and consists of two parts divided by a wall running east and west, the part to the south of this wall having but one floor, while the part to the north has three floors.

When the building was first under consideration a number of very difficult problems presented themselves, partly in the way of finding sufficient room in already overcrowded grounds, and partly in the way of making the building harmonize with the other University buildings. In order to carry on the instruction required, a boiler room was necessary, which had to be placed on the outside of the building in order to facilitate the delivery of coal and the removal of ashes. Then, too, there was the problem of stacks, two of which have been provided for experimental purposes and the necessity of good light and large rooms, so that it was difficult to make the building look attractive. The architects considered the question with great care and arranged a scheme by which the boiler room and other unattractive parts will be eventually hidden when the entire group of buildings for the Faculty of Applied Science is completed.

THERMODYNAMIC LABORATORY—SUCTION GAS PRODUCER PLANT.

The view on this page shows the building as it will finally appear. The front will be to the west and it will face on the main University road which runs north from College St., directly opposite University College. To the north of the building it is proposed in future to run a cross road east from the one above mentioned, the new road separating the Mechanical Laboratories and the building which will in time replace the present Engineering Building. At present there is only a very narrow passage between the two buildings. On the south the building will be connected to the future extensions to the Chemistry and Mining Building, which extensions are to be so planned that almost the entire south side together with the boiler room, which is now exposed, will be hidden.

The building will thus have a fine appearance and will with the Chemistry and Mining Building form a fine, large block quite in keeping with the nature of the work being done by this Faculty of the University.

Owing to the other pressing needs it was felt by the Board of Governors that it would be impossible to erect the entire building at the present time and as laboratory accommodation had to be provided the part containing this was erected and a reasonable number of class rooms provided in it, while the front part, which will contain more rooms of this nature, has had to be omitted for the present.

The Thermodynamic Laboratory

Beginning with the space devoted to the heat engines and general mechanical work, we enter the Thermodynamic Laboratory. This laboratory occupies with the boiler room, the whole south half of the building and exclusive of the latter is 156 feet long by 60 feet wide with roof light throughout, there being no windows in any of the walls. It is divided into two parts, one being 40 ft. wide and the other 20 ft. wide, running the entire length of the room. The wider part has a clear height of 23 feet at the sides, being considerably higher in the centre. The narrower part has a clear height of 12 feet, and is divided up into smaller parts, there being eight small rooms, to be described later, and a space for delivery and unpacking of goods. The light is obtained from the roof and is as near perfect as can be expected. The ventilation is also very good being obtained by opening windows in the roof, a method which works so well that the building can be kept quite cool even with all the machines operating at once.

Internal Combustion Engines.—The equipment in the two parts of this laboratory may now be described in some detail, beginning with that in the larger part. The west end of this has been devoted to gas, oil, and other internal combustion engines and the equipment consists of a 10 h.p. engine built by Fielding

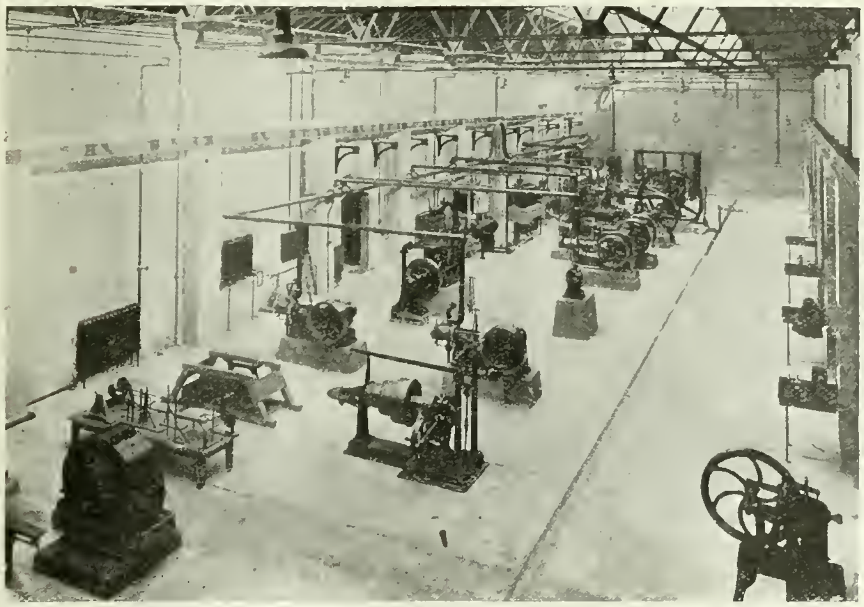
NEW LABORATORY OF FACULTY OF APPLIED SCIENCE CONTAINING STEAM, GAS AND HYDRAULIC EQUIPMENT.

& Platt, of Gloucester, England. This engine has a cylinder 7 in. in diameter and 14 in. stroke and has been specially built for experimental work. It is designed for variable compression, so that it may be adapted for use with different classes of fuels; and it is further equipped with three types of igniting gear, viz.: hot tube, high tension electric and a magneto gear, an arrangement being made so that the point of ignition may be varied at will while the machine is running. There is also a convenient method of varying the speed, and the use of heavy fly-wheels prevents great speed fluctuations at different speeds and loads. The engine is also fitted with vaporizing apparatus so that it may be run with oil, and has properly designed valves for the use of suction gas.

Adjacent to this engine is a larger one built by the National Gas Engine Co., Ashton-under-Lyne, England. It has a cylinder diameter of 9 in. and runs at a normal speed of 200 revolutions per minute, giving 22 h.p. on city gas. This machine is a very fine sample of a gas engine, being exceptionally heavy and having two massive fly-wheels which give steady speed. It has variable compression as in the case of the Fielding & Platt engine, and is designed for the use of either city or suction gas. It has only the magneto form of igniter, but the point of ignition may be altered without stopping the engine, which is noiseless in operation.

As already explained, both the above engines may be operated by city or suction producer gas. In the former case the gas is drawn directly through a meter where it is measured. When the suction gas is used the latter is drawn from a producer in the small room in the south-west corner of the building. This producer, which was built by the Canada Foundry Co., of Toronto, consists of a generator complete with vaporizer, two scrubbers, and an expansion box from which the gas is delivered to a pipe conveying it directly to the engine. It is arranged so that fuel consumption tests may be made with it and the action of the producer carefully and accurately studied.

Adjacent to the Fielding & Platt engine and on the north side of it a test floor has been arranged so that engines of fairly large size may be conveniently tested, and it is hoped that various firms will, from time to time, place some of their engines at the disposal of the laboratory for examination and research work, as it is believed that this will prove of mutual benefit to the manufacturer and the University. This test floor is at present occupied by one of the earliest types of gas engines built by the Otto Gas Engine Co., Philadelphia. The engine has given good service in the engineering building for nearly twenty years and is retained to give some idea of the development of the gas engine of late years and because of its historical interest. It is one of the slide valve type of engines with the old form of gas flame igniter, and is in good condition for test and comparison with the newer machines.



THERMODYNAMIC LABORATORY—GENERAL VIEW FROM WEST END.

The space immediately in front of the engines just mentioned is used for two smaller test floors for gasoline and other similar small engines. Each floor is three feet square and has adjustable slots by which any small engine may be accommodated.

A marine gasoline engine with a cylinder 6 in. diameter and 6 in. stroke has been given by the Canadian Fairbanks Co., Toronto, at a nominal price and has been placed on one of the test floors mentioned and set up for experiments. This engine is to be equipped with an optical indicator made by Dobbie, McInnes & Co., Glasgow, so that its action may be accurately studied.

On the south side of the large room is an Ericsson air engine which serves to illustrate the action of this type of engine and give figures on its economy. It is arranged to be run by city gas and a brake has been arranged to measure the brake horse-power at the same time as the indicator diagrams are taken. The efficiency of the machine as a pumping engine may also be found by allowing it to lift a measured quantity of water against a measured head.

Other Apparatus.—Proceeding farther east along the large room there is seen a fan on which experiments on its efficiency are to be made.

A little farther down is a slide valve model. This model is very complete, and has been constructed so as to give results on almost any design of simple slide valve or link motion. The length of connecting rod is adjustable, as well as the angle of advance and throw of all eccentrics, the length of eccentric rods, radius and point of support and suspension of the link, etc.

There is also a journal oil tester built by Riehle Bros. of Philadelphia, and having various adjustments. The journal used in the machine is a full-sized railway car journal, and the design is such

THERMODYNAMIC LABORATORY—DE LAVAL STEAM TURBINE WITH WILLANS VERTICAL AND LEONARD HORIZONTAL ENGINES IN BACKGROUND that the actual pressures and speeds occurring in practice may, within limits, be obtained. The friction of the journal is conveniently read off on a scale beam.

The Steam Engines.—We pass on now to the steam engines. The first of these are two of comparatively small size which were presented to the Laboratory by Messrs. E. Leonard & Sons, London, Ont. These engines are used almost exclusively for exercises in valve setting, and have cylinders 6 in. and 7 in. in diameter respectively, and 8 in. stroke, but have different types of slide valves. The one to the south has the ordinary D form of valve and a special design of eccentric may be independently varied. The other engine has a special type of inside admission valve, which is partially balanced and so designed that the engine may be operated without the steam chest cover and thus show the motion of the valves; this engine has an eccentric of the same type as the one just described.

Both of these engines are fitted with throttling governors and suit the work for which they are designed exceptionally well, the kindness of the donors being much appreciated.

Next to these is a 15 h.p. de Laval steam turbine, built by Greenwood & Batley, Leeds, England. As is the case with most of the other machines, this turbine has been specially arranged for experimental work and has six nozzles altogether, some of which are for non-condensing operation and the others are used when running condensing. The rotor of this turbine runs at a speed of about 24,000 revolutions per minute, the power shaft running at one-tenth of this speed. This turbine has been found very useful as an experimental machine.

Behind the turbine is a Willans vertical, high-speed compound engine. This machine was purchased to drive the turbine pump in the old laboratory, but with the building of the new one an extra pump had to be installed so that a larger engine had to be purchased to supply the necessary power and the Willans engine became available for experimental work. It is of the high-speed type, having a normal speed of about 460 revolutions per minute, and developing at this speed 75 h.p. with a steam pressure of 125 pounds per square inch.

The design is rather peculiar, as there is no valve gear evident externally. The piston rods are hollow and the piston valves are operated by eccentrics forged solid to the crank pin. In this particular engine there are two high pressure and two low pressure cylinders, the high pressure cylinders being above the corresponding low pressure ones; all are single-acting, and in order to prevent shock on the crank at the end of the stroke there is an air piston below each pair of cylinders, the pressure of the air compressed by it being sufficient to make a continual downward thrust. The crank bearings have no upper cap and require none for the above reason.

The steam cylinders are respectively 10 in. diameter and 14 in. diameter, and all pistons have a stroke of 6 in.

Engines of this type have met with great favor in England because of the low steam consumption, a paper by Mr. Willians read before the Institution of Civil Engineers in April, 1893, giving some very valuable information along this line.

THERMODYNAMIC LABORATORY—McEWEN AND LEONARD-BALL ENGINES WITH CONDENSING PLANT AT LEFT.

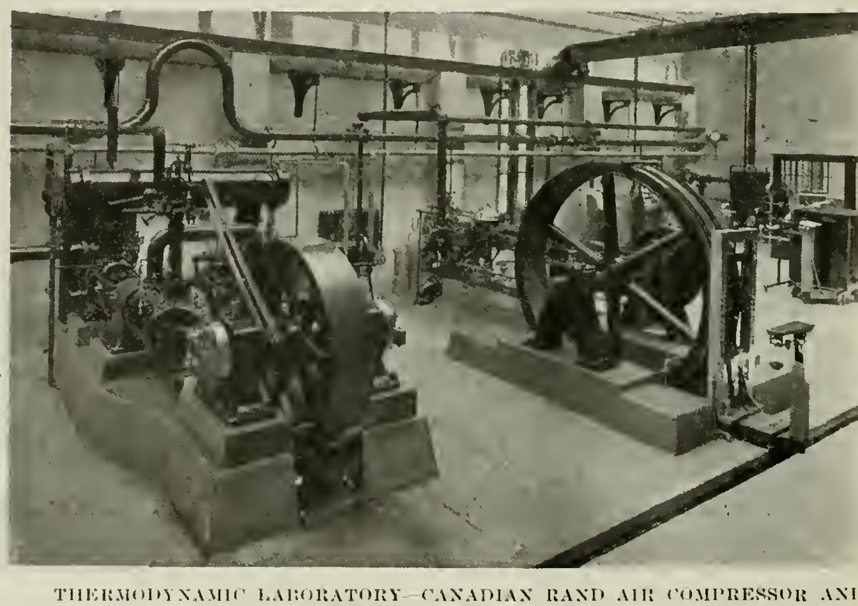
A passage leading to the door separates these engines from the McEwen high-speed horizontal engine. The cylinder is 8 in. diameter and 7 in. stroke, giving 18 h.p. This engine has a good form of shaft governor, so that it is well adapted to instruction in the use and action of such governors, as well as providing good indicator practice. As it is connected like the other machines to the surface condenser, tests on the economy of the machine may be conveniently made.

The Leonard-Ball tandem compound engine is also provided with a shaft governor of different type from the one mentioned above. This engine is horizontal and has cylinders 7 in. and 12 in. diameter by 10 in. stroke, and will thus develop about 29 h.p. at 250 revolutions per minute.

There are two types of valves in the engine, the one in the high-pressure cylinder being a Ball valve with double inside admission. The valve is partly balanced, gives rapid cut-off, and on account of the double parts has a comparatively small travel. In the low pressure cylinder a balanced D slide valve is used.

This engine provides instruction in the tandem type of machine as well as practice with a shaft governor.

Next to the engine just described is the air compressor, a machine built by the Canadian Rand Drill Co., Sherbrooke, Quebec, and purchased through Mr. Haight of the class of '96 at one-half the actual commercial selling price. This machine is of the cross-compound, steam-driven, two-stage type, having the low pressure air cylinder arranged tandem with and behind the low pressure steam cylinder, and the high pressure steam cylinder in front of the high pressure air cylinder. The steam cylinders are respectively 9 in. and 16 in. diameter, while the air cylinders are 9 in. and 14 in. diameter, all having the same stroke of 12 in.; the normal speed is 160 revolutions per minute and the rated capacity 340 cu. ft. of free air per minute,



THERMODYNAMIC LABORATORY—CANADIAN RAND AIR COMPRESSOR AND BROWN STEAM ENGINE.

with a steam pressure of 125 pds. per sq. in.

The fly-wheel is arranged with inside flanges so that a brake may be applied to it, and by disconnecting the air cylinders the whole may be run as a cross compound steam engine. Both steam cylinders are provided with Meyer cut-off gear, giving considerable elasticity.

The low pressure air cylinder has Corliss inlet gear and pressure gauges and thermometers are arranged for experiments of various kinds.

An air receiver is installed and piping runs to the mining building, delivering air when required to drive a rock drill.

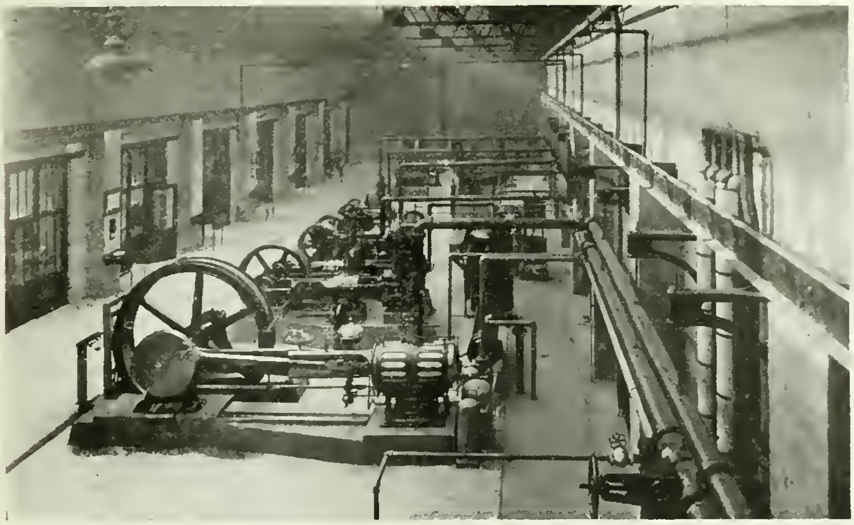
This machine is of great value and usefulness and forms a very good piece of experimental apparatus.

When the engineering building was opened it contained a 50 h.p. Brown automatic cut-off engine built by the Polson Iron Works, Toronto, and this engine has been set up again in the new laboratory. It is of special design for experimental work and has jackets on both heads and on the barrel, all jacket drains being separate in order that the condensation in each part may be independently determined. The clearance volumes in this particular machine are also made specially small, and it runs quite economically.

The Steam and Exhaust Piping.—An examination of the photographs will show the general arrangement of the steam piping. It consists of a single line of 5-in. pipe running through the boiler room and about 90 ft. along the wall of the Thermodynamic Laboratory, also of a $3\frac{1}{2}$-in. pipe running from the northerly boiler up to the Brown engine connection. The latter pipe is designed so that it is possible to run a complete engine and boiler test on the Brown engine and the one 50 h.p. boiler. Connections are also made so that this boiler may deliver steam to the 5-in. pipe and the Brown engine may also be arranged to draw from the same pipe.

The 5-in. pipe has two large expansion bends, the one near the Brown engine being distinctly visible in the photographs. All connections on this line are flanged and each engine draws its supply from the top of the pipe, thus avoiding water from drainage and condensation.

All engines are arranged to run either condensing or non-condensing, two surface condensers with independent air pumps being installed for the former condition of operation. There are two 6 in. exhaust pipes, one of which is connected to the condensers, the other through the heater to the atmosphere. Both of these are arranged with flanged connections and the system is so designed that by the removal of a few bolts any engine may be changed from the atmospheric exhaust to the condenser in a very short time, it being only necessary to change one blank flange and turn an elbow through 180 deg. The operation is thus accomplished without the use of valves and the measurement of the condensed steam becomes at once accurate. The system also permits the running of almost any pair of engines condensing, and at the same time the operation of all the other engines non-condensing. Proper drainage is provided for all piping, and it has all given perfect satisfaction up to the present time.



VIEW OF THERMODYNAMIC LABORATORY FROM EAST END

The cooling water piping is shown below the steam piping, but possesses no special features.

Brakes.—The writer believes that brakes should be of the simplest form possible so that students get accustomed to the handling of the cheapest and most accessible types. The brakes used are, therefore, rope brakes or else simple forms of the Prony brake, the wheels being generally provided with inside flanges so as to avoid annoyance from the cooling water.

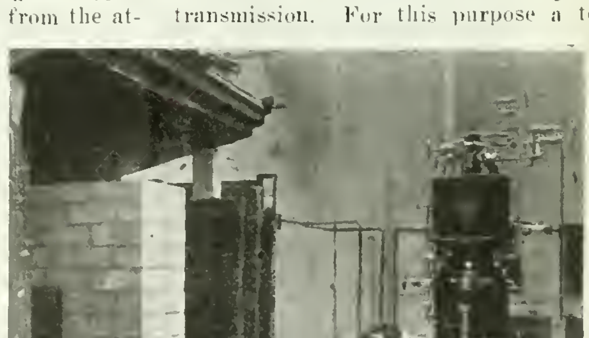
The remainder of the space in this part contains a test floor, which permits any engine submitted for test to be easily set up and run either condensing or non-condensing. There is also a space for the testing of injectors, these being arranged in a convenient and neat pipe stand ready for operation.

At the end of the room is a Cochrane feed water heater purchased from the Canada Foundry Co., Toronto.

Some space has been left at this end of the room for expansion, and it is hoped that in the near future a triple expansion engine will be installed here.

Small Laboratory Rooms.—The narrower southerly portion of the Thermodynamic Laboratory (with the exception of the two end bays, which are used for delivery and unpacking) is divided into eight small rooms for special work of various kinds. The first two rooms are connected by a door, and are used as a small repair and instrument-making shop, in which special apparatus is made as required. This shop contains a new 20-in. Bertram engine lathe of modern construction built by John Bertram & Sons, Dundas, Ont. There is also a 20-in. McDougall drill, an emery wheel and a wood-turning lathe, together with a good equipment of tools. The shop is driven by a Westinghouse motor.

The third room will contain the apparatus for testing various machine elements and the methods of power transmission. For this purpose a torsion dynamometer has been purchased from J. Amsler-Laffon & Sohn, Schaffhausen, Switzerland, which may be used for the transmission of any power not requiring over 540 ft. pds. twisting moment. As the machine may be safely ru



Thermodynamic Laboratory—Refrigerating Plant with Test Chamber for Building Materials on Left.

at high speeds its possibilities in the way of power transmission are fairly great, and it thus serves as a very flexible instrument. This instrument will be used to deliver a measured quantity of power to a belt or rope or any form of bearing or machine element, and the efficiency of the transmission or element may be directly determined by absorbing the power by a brake at the driven end.

The fourth room contains a refrigerating machine of three tons capacity, built by the York Manufacturing Co. of York, Pa. It is of the ammonia compression type and the horizontal steam engine and vertical compression machine are connected to the same crank. The complete accessory equipment has been provided and arrangements made for indicating the steam and ammonia cylinders and for taking the temperature at every desirable point in the plant.

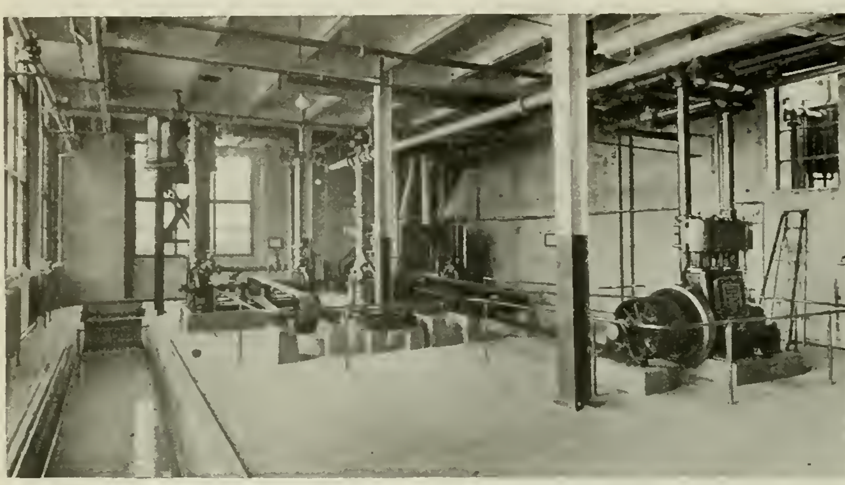
The next room has been set apart for instruments, and in it are kept all of those used in both the Thermodynamic and Hydraulic Laboratories. All instruments are given out to students on application by ticket and are charged up against the one receiving them. When an instrument is returned it is examined and if in proper condition is put in its place, but if found to have been damaged by the student, the cost of repair is charged against him. By this system careless handling or loss of instruments is avoided.

The sixth room is used as a third year study room, while the seventh is to be used for the testing of lubricating oils and the determination of the heating power of gases and fuels of various types. A Sargeant gas calorimeter has been purchased and is to be used in this room.

The last room is occupied by the suction gas plant, described earlier in this article.

Just in front of these rooms and secured to the crane piers a number of tables have been placed, on which work on gauge and indicator calibration may be carried out, the gauge calibration being done by Crosby gauge testers, while the indicator springs are calibrated by means of steam supplied at various pressures.

The whole of the larger part of this laboratory is served by a three-ton travelling crane of about forty feet span. This crane is operated by hand, and has proved of inestimable value in the placing and handling of the different pieces of apparatus.



HYDRAULIC LABORATORY—ESCHER, WYSS AND GWYNNE PUMPS DRIVEN BY BELLIS & MORCOM ENGINE.

The Hydraulic Laboratory

The Hydraulic Laboratory occupies the north half of the building, and is located in the basement and ground floors, each of which is 40 ft. wide by 113 ft. long. The light for this laboratory had to be obtained from the north and east, and as only one large window could be placed in the east end, the north light had to be depended on almost entirely. Large windows running up the full height of the two laboratory storeys were designed, which take up three-quarters of the entire side of the building. This gives a good architectural effect, and while not giving as good light as is obtained from the roof in the Thermodynamic Laboratory, yet it is quite satisfactory.

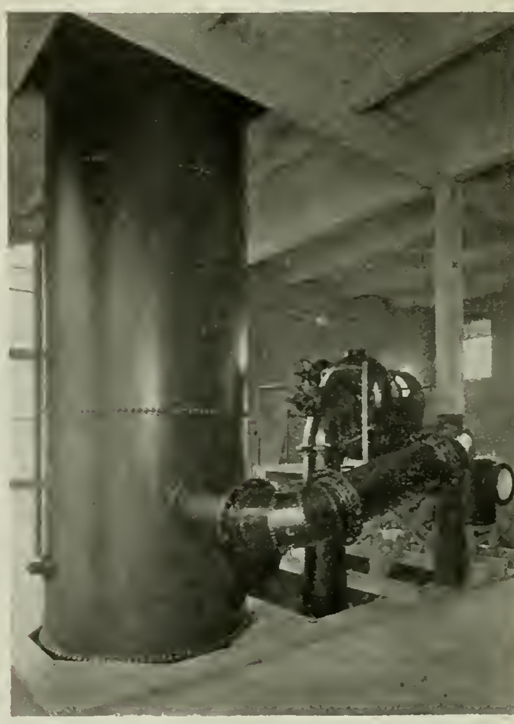
On account of the large area of glass exposed to the north, trouble was anticipated in the way of heating the building, and arrangements were made to put double windows throughout, which, however, have not been necessary.

The lower storey or basement is 18 ft. high, and contains the well, the pumps and the engine for driving them, the measuring tanks used for calibrating the orifices and weirs above, several large troughs and the main part of the piping for the entire laboratory, while the upper floor, which is 15 ft. high, contains the orifice and weir tanks, the experimental centrifugal pump with its weir tank and motor, the various pipes for friction experiments, the meters, and also the various types of turbines and other apparatus.

Beginning with the top floor at the west end, part of the space had to be left clear for a hoist hole, the first piece of apparatus being a centrifugal pump of special construction for experimental work. This pump was designed along theoretical lines, and has carefully polished vanes on the runner; it is mounted on a weir tank so that the discharge may be very easily measured, the various heads under which it is operated being obtained by throttling. The pump is driven by a variable speed motor, by means of which the power put into the pump may be determined and its efficiency readily obtained. The arrangement has been found very satisfactory, as it gives the student an opportunity to study the effect of variations in speed, discharge, pressure and efficiency of the machine.

Adjacent to this are two orifice tanks and a weir tank used mainly for instruction in the use of orifices and weirs. Various sizes and shapes of orifices are inserted and operated under several heads as measured by hook gauge. The water is discharged through 6-in. pipes into the calibrating tanks below, of which there are six, two for each orifice and weir, each tank having a capacity of about 50 cu. ft.

These calibrating tanks are of some interest, and have been carefully designed so as to be entirely operated by the movement of a single lever. When the lever is put in one extreme position, one tank is made to fill, its outlet valve being closed, while the outlet valve of the other tank is at the same time open. For the small discharges the tank fills so slowly that the upper surface is quite smooth and undisturbed, and, therefore, the exact height of the water in the tank, and consequently the volume of the water at the moment of dumping is easily observed, but where the discharges are large, the surface of the water in the calibrating tank is so disturbed that accurate observations of this kind are im-



HYDRAULIC LABORATORY, FRANCIS HORIZONTAL TURBINE COUPLED UP TO 5 FT. 6 IN. STANDPIPE.

possible. To obviate this trouble the mechanism is so designed that by moving the lever to an intermediate position the outlet valve on the other tank is closed, and the discharge turned into it, the water surface in the first tank coming to rest at once its height is easily observed, after which the lever is pushed to the other extreme position, the outlet valve of the first tank being thus opened without disturbing the conditions in the second tank.

The quantity of water in the tank after filling may be found by direct weighing or by reading the level in an attached gauge glass.

The floor has been constructed with an opening protected by a rail, so that the student may observe the whole operation at one time and thus get a clear idea of the process of calibration.

In order that experiments on these tanks and orifices may be carried on without interfering with the other work, a large reservoir, provided with an overflow, has been placed above them, and from this they draw water. So long as there is enough water passing into the reservoir to cause some overflow the experiments may be carried on at various heads and discharges without difficulty.

From this reservoir a $1\frac{1}{4}$-inch pipe is also run to a hydraulic ram which can thus be operated under a head of about 10 ft. and with a drive pipe about 40 ft. long.

A three-inch Venturi meter has been installed on a pipe in which other meters will also be placed. This meter is rated by sending the discharge from it through one of the orifice tanks already described, using the coefficients determined by actual experiment.

A little to the east of the centre of the laboratory an elevated platform about 25 ft. long and 7 ft. wide has been erected for the impulse turbines. At present two turbines are in use, one a Doble wheel made by the John McDougall Caledonian Iron Works, Montreal. This is a very well finished wheel of 12 in. dia., and as it has glass sides the action of the water may be very conveniently studied. The needle regulating nozzle gives a very perfect stream.

The other machine is an 18-in. wheel made by the Pelton Water Wheel Co., and although not so well constructed, it represents a very common class of water-wheels in use to-day.

The water used by these turbines is measured by passing it through a weir tank and then back to the pump well. For the use of these turbines it is possible to get a discharge of 1 cu. ft. per sec. against a maximum head of about 500 ft.

At the east end of the room is a large stand-pipe 32 ft. high and $5\frac{1}{2}$ ft. dia., supported on a stand in the basement so that it reaches up into the roof of the building. This stand-pipe is used as a reservoir for the reaction turbines and also for any experiments requiring constant but not very high heads. This stand-pipe has a 14-in. nozzle on each side for the attachment of turbines and also a large nozzle 30 in. dia. on the front so arranged that orifice plates and tubes of various sizes may be attached and experiments made at higher heads than is possible in the open orifice tank. The water is delivered to the stand-pipe through two 8-in. pipes near the bottom and by a convenient arrangement of baffle plates there is no trouble caused by the surging or eddying of the water.

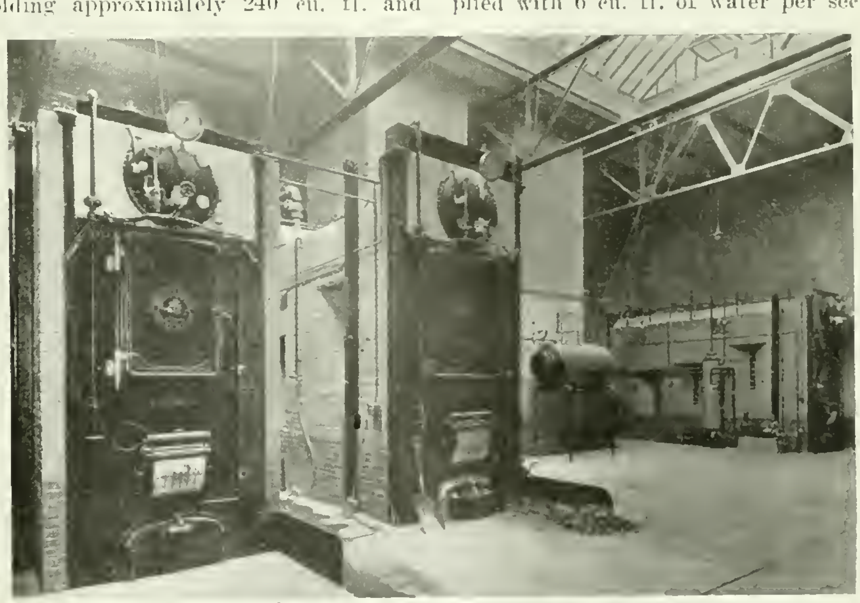
In front of this stand-pipe is a large weir tank 20 ft. long by 6 ft. wide, which is arranged with a sharp crested weir $4\frac{1}{2}$ ft. wide with end contractions. This plate may, however, be changed so that weirs of different sizes, with or without end contractions, may be easily inserted. The total depth of the tank is 3 ft. 9 in. and the depth of water below the crest of the weir is 2 ft. 3 in.

The weirs used in this tank may also be calibrated by means of a pair of measuring tanks in the basement, each holding approximately 240 cu. ft. and both being connected to the weir tank on the down stream side of the weir by 12-in. galvanized iron pipes. Hydraulically operated valves are to be used in connection with these calibrating tanks and are so designed that a single lever is made to do the whole operation of filling emptying as in the case of the smaller tanks already described. This lever, as in the former case, has three positions when operating, the extreme positions indicating that one tank is filling and the other emptying, while the intermediate position is used when both discharge valves from the tanks are closed and one of the tanks is filling. It is believed that very accurate co-efficients can be determined by this method.

There are three reaction turbines available for testing. The smallest one has a 6-in. runner and was made by Wm. Kennedy & Sons, Owen Sound, Ont. It has been set up in a steel penstock and connected to the stand-pipe by a 14-in. steel pipe containing two elbows. This pipe is to be used for experiments on the flow through elbows, the conditions being examined by a Pitot tube. This 6-in. turbine has been operated under a total head of over 25 ft. including about 5 ft. in the draft tube. The horse-power is measured by Prony brake and the discharge is determined from the $4\frac{1}{2}$ ft. weir.

A 9-in. McCormick turbine with cylinder gate has not been set up but is left to give the student practice in the measurement of such wheels and to enable him to study the forms of the vanes.

The latest turbine to be installed is one purchased recently from the noted hydraulic firm of Escher, Wyss & Co., Zurich, Switzerland. This wheel, of the horizontal Francis type, has a well designed spiral casing and a runner nearly 14 in. dia. The gates are of standard design, operated through a ring by a hand wheel on the casing. A conical draft tube over 7 ft. long is used and the wheel will deliver 10 H.P. when supplied with 6 cu. ft. of water per sec. at a head of 20 ft. As this wheel is of the very best construction it forms an excellent addition to the experimental equipment.



BOILER ROOM—ONE 100 H.P. AND TWO 50 H.P. BABCOCK & WILCOX WATER TUBE BOILERS.

The maximum quantity of water available for these reaction wheels is about 6 cu. ft. per sec.

Along the north side of this floor near the windows arrangements are made for the testing of the friction in fire hose and iron pipe. A $2\frac{1}{2}$ in. iron pipe 50 ft. long has been set up, also a 50 ft. length of fire hose, and the frictional losses are determined. The flow in the iron pipe is also studied by the Pitot tube, and curves showing the distribution of the velocity are plotted.

The basement contains, in addition to the orifice and weir calibrating tanks already mentioned, the well and pumping plant. All water used in the laboratory is drained back to a large well from which it is pumped into the system and used over and over again.

There are two sets of turbine pumps used for this purpose, one of which was built by Messrs. Gwynne, London, England, and the other by Escher, Wyss &

Co., Zurich. Each set consists of two two-stage pumps fastened to a common bed plate and driven by a single pulley, couplings being arranged so that either pump may be separately operated. Further, the two pumps on the one base are piped together in such a way that they may be made to deliver into the piping in three ways, viz., (a) separately, (b) in series, (c) in parallel. A connection is also designed to connect the discharge from the Gwynne pump to the suction from the Escher-Wyss pump, putting the two sets in series for very high pressure work.

Each of the Gwynne pumps will deliver 1 cu. ft. per sec. against 125 ft. head, while the other pumps have the same capacity against 150 ft. head, the discharge at lower heads being, of course, much greater.

As suitable piping has been arranged in the laboratory, it may thus be seen that the whole arrangement of the plant is very flexible, permitting (a) the operation of the four pumps separately, thus allowing four absolutely independent experiments at one time; (b) the operation of the two sets separately on separate experiments; (c) the operation of the two sets in series for high pressures and moderate discharges as are required in fire streams and impulse turbines, giving 1 cu. ft. per sec. at 500 ft. head; (d) the operation of the two sets in parallel giving about 6 cu. ft. per sec. at the heads available in reaction turbine work in the laboratory.

The pumps are of modern design, the Escher-Wyss set having been installed quite recently. They run at speeds of 1,300 and 1,400 revs. per min. respectively, and are belt-driven from a jack shaft placed on the floor, vibration of the building being thus entirely avoided. The jack shaft is driven by a Belliss Morcom engine of 130 H.P. running at 530 revs. per min. This engine is a very fine piece of workmanship and runs quietly and without vibration. The exhaust from the engine is used to heat the building.

Arrangements are being made for the insertion of a transmission dynamometer in the Escher-Wyss pump drive so that its efficiency may be determined with greater accuracy than can be obtained by indicating the engine.

A large trough 6 ft. wide, 4 ft. deep and 110 ft. long has been provided in the basement which is used for the rating of current meters and tubes and other work of this nature. It is believed that this will be especially useful in view of the rapid power development going on in Canada at the present time.

There is sufficient space still left for further expansion.

The Boiler Room

This room contains three Babcock and Wilcox boilers, all built for 200 lbs. pressure.

The 100 H.P. boiler is provided with a superheater while the two 50 H.P. boiler have been set up independently and one is arranged with a special type of setting so that valuable comparative results may be obtained.

A separate feed pump is provided for each boiler so that separate tests may be made on each one.

A steel breeching conducts the products of combustion to the stacks, of which there are two of brick, each 100 ft. high and 36 in. internal diameter. An arrangement of dampers allows these stacks to be operated at different powers on the same day and thus reliable experiments may be made on the capacity of each stack.

The room is light and airy, being 70 ft. long, 45 ft. wide and 26 ft. clear height. All the light is obtained from the roof and is very satisfactory indeed.

Offices and Study Rooms

AT the north-west corner of the building, immediately west of the Hydraulic Laboratory, there is a further space partly occupied by the stairways and halls and partly by other rooms. These rooms are as follows: In the basement the students' room with shower bath, on the first floor the professor's and the lecturers' rooms while the top floor is occupied by a lecture room and private lavatory.

An entire floor above the Hydraulic Laboratory is divided up into students' study rooms, a lecture room, a library, demonstrators' rooms, and students' lavatory. All of these rooms are comfortable and bright and the students' rooms are provided with convenient tables and a locked drawer for each person.

Artificial Lighting

The large Thermodynamic Laboratory is lighted by ten Nernst lamps, which are attached to the trusses and provide sufficiently good light to do any work required. The Hydraulic Laboratory is lighted by tungsten lamps, there being ten to each floor.

The remainder of the building, with the exception of the boiler room, which also has a Nernst lamp as well as incandescent lamps, is lighted entirely by incandescent lamps, which seem to give very good satisfaction so far.

Conclusion

This article would be incomplete without making mention of the work of Dean Galbraith. It was he who gave the writer his first real insight into the profession which he honors and it is on the foundation laid by him that the writer has built in striving to design a laboratory that shall give the future engineers the proper basic principles on which their life work depends. The teaching of principles is vastly more important than the teaching of a few facts, the desire to teach these principles in such a way as to make the practical application clear is a thing for which Dean Galbraith has always stood, and the writer's association with him and the engineering world have given him the desire to make the laboratories described such as shall be a real help to the student when he gets into active practice.

Acknowledgment is also made of the help given by the members of the staff in Thermodynamics and Hydraulics who assisted by many suggestions and by the sacrifice of much time in making the building and equipment such as it is.

It will be noticed that all of the units in the two laboratories are comparatively small and are such as can be handled with comparative ease. The writer believes this to be a valuable feature of such a laboratory, as the student can readily comprehend the whole machine at one time, and therefore does not lose the connection between the different observations as he is apt to do with the larger units where the parts are so much separated. The results obtained are, the writer believes, quite as valuable, from the point of view of the instruction to the student when obtained from reasonably small machines as from very large ones.

No machine in the laboratory is used for electric power or for any other than experimental purposes, so that all pieces of apparatus are always available for experiment or research.

OBTAINING DRAUGHT WITHOUT HIGH CHIMNEYS

IN ordinary practice, the use of the chimney is to cause a draught to make the fire burn, or in other words to cause the passage of a sufficient volume of air at a moderate velocity to supply oxygen enough to enable the fuel to be consumed to the greatest advantage, and incidentally to carry off the burnt (and unburnt) products arising through the combustion of the fuel. So far as it goes this is all right; but in very many cases it leaves much to be desired. To secure the most efficient heating it is necessary that the fuel should be reduced to its highest gaseous state—in the case of carbon this would in ordinary cases be carbonic acid—and to get to this stage it is necessary that large volumes of air must be drawn through the fuel at a comparatively low velocity. This is best done by means of exhaust fans of fairly large size, the discharge from which is passed through stacks of brushwood not too tightly packed together and kept damp by some simple method of water distribution and spraying.

Invar is a nickel steel containing about 36 per cent. nickel, together with about 0.5 per cent. each of carbon and manganese. Its most remarkable property, says the *Iron and Steel Trades' Review*, is its extremely small thermal expansion at ordinary temperatures, owing to which quality it is now used for making steel tapes for precision measurements. Its mechanical properties are about as follows: Tensile strength, 50,000 to 85,000 lbs. per square inch; elongation, 40 to 50 per cent.; reduction of area, 40 to 65 per cent.; and Brinell hardness, 160.

PRELIMINARIES IN MACHINE PART PRODUCTION METHODS—III.

By F. Scriber.

THE examples so far shown have been of operations performed on one machine only, and as the best way to become familiar with a system is to use it in its various forms, a part to be manufactured on various machines is illustrated by Fig. 7; the subject in this case is a bracket, No. 2197-D. The material is cast iron, and a sketch of the subject is shown under that heading; under machine, the word "Miscellaneous" is used as this aptly describes the machining operations on this part. As the various notes in the two columns describing the operations of the tools tell the story, further reference in regard to this sheet is unnecessary.

FIG. 8.

For Miscellaneous Work

The next two illustrations, Figs. 8 and 9, show operation lists which vary slightly from the foregoing examples. In these lists a column is provided for the operation numbers at the left and a column for the tool number is at the right of the sheet. These lists of tools describe "Miscellaneous machining operations, that in Fig. 8 being an ideal type on which the first operation is to disc grind the surfaces marked A on a disc grinder. Of course, no special tools are required for this operation. The second operation is to mill end B, and the third operation is to mill end C. A special fixture is required to perform these operations, and in the column headed "Tool No" it will be noticed the number of this fixture is 209. Of course, keeping these tool numbers straight means an extra job for the production man, but this is sometimes necessary when no other means of keeping records is available.

FIG. 9.

The list of tools, Fig. 9, is for an adjustable carrier, No. 889-Y, made from machine steel by miscellaneous operations. The operations on this part are quite numerous and varied, and require in all six special tools, which are numbered on the sheet.

Referring to Fig. 10, we note that the machine operations on the part there illustrated are: planing, milling, boring and drilling, and we next turn our attention to the bottom of the illustration and read the note, which says, "As but 112 of these parts are to be made, no special tools can be allowed except where the word (make) appears." The operations on this list of tools are written in the usual manner, while the column headed "Tools Required" is used chiefly for descriptive purposes, emphasizing where the work is to be located.

Sketch of Subject
Material Iron casting
Machine Milling, Boring, Drill, Planer

Operation	Tools Required
Plane flat surface	Jack up as many as practical on planer
Straddle mill bosses	Use standard angle iron and gang of straddle milling cutters on horizontal machine, clamp part against finished surface, rest on lower edge
Bore main hole	Horizontal boring machine locate thus: boring bar, locating block, clamps, spot center of boss for hole
Drill & counterbore holes	Steel template (make)

Note—As but 112 of these parts are to be made, no special tools can be allowed except where the word (make) appears

FIG. 10.

Gang-Tool Operations

These lists of tools would be incomplete if at least one illustration was not included showing operations and fixtures for gang working some part. In Fig. 11, the sliding block, No. 21984, which is an iron casting machined by gang milling, is illustrated under the heading "Sketch of Subject." The operations on this part are two in number, namely, mill finished

FIG. 11

portion on four-inch surface, and mill upper side. Sketches of tools required for performing these two operations are illustrated in the column provided for this purpose. These tools consist of a gang of cutters used on a horizontal milling machine and gang fixtures for milling four parts at each setting.

As stated at the outset of this article, these "Lists of Tools" are a plain statement of facts, and no attempt has been made to include or make these lists contain data for future reference, such as time records, etc., as the one object of these lists is to insure the economical routing of work by some one reputed to know how, and who will only make such special tools as will expedite work with the desired accuracy.

MACHINISTS' INSTRUCTION COURSE—XII.

By J. Davies.

THE principal operations in chuck and face plate work are boring and facing. The boring is done by some form of drill or boring tool, although a drill is not always necessary except in drilling from the solid. In drilling from the solid make a good-sized centre with the centering tool, to give the drill a chance to start true. A twist drill is best for drilling holes out of the solid. Never put a drill in the finished size of the hole at the first cut unless it is a very rough job, as the hole is almost certain to be untrue or too large, or both. The best and most accurate finish is done with a reamer; when it is intended to finish with a reamer, bore as large a hole as possible with a drill, while leaving sufficient stock to allow the hole to be trued up with a boring tool, and leaving about 1-64 in. for finishing with reamer. If the work is a

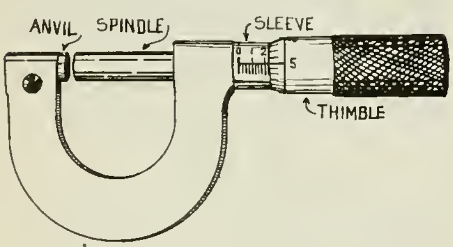

FIG. 48.

casting with a cored hole in it, an old-fashioned home-made flat drill is about the best thing to use preparatory to the boring tool; the sand in the cored hole would soon rub the clearance off a good twist drill, besides finally running out of truth. The flat drill should be fastened securely in the tool post where it practically becomes a boring tool; it also makes a very good substitute for a reamer and if made parallel for about ¾ in. makes a smooth hole.

General Boring Work

The conditions under which a boring tool works are unfavorable for good results, as the diameter and length of hole to be bored impose unfavorable handicaps. The best results are obtained by using a round steel bar, fitted into a substantial holder which can grip the bar in any position, having the bar as nearly the full size of the hole as possible, and the cutting edge of the tool in the centre of the hole. If the tool is in-

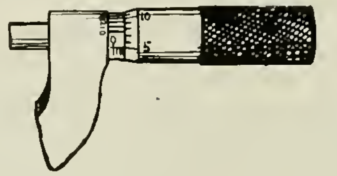

FIG. 49.

clined to chatter make the nose narrower and give the tool more side clearance. It is easier to prevent chattering than to take the chatter out afterwards.

Some jobs can be handled better by reversing the method of operation, that is, by fastening the work to the lathe carriage, and boring out with a tool in a bar that revolves between the centres of the lathe. This method is handy for heavy work, or work with very large holes to bore. A well-finished hole can be bored exactly to size, by having the cutter turned up in the boring bar to the required size.

Extremely heavy work such as large engine cylinders, are usually bored out, with a boring head carrying one or more tools, arranged to slide by power along the revolving boring bar. Various devices are employed to feed the boring head along the bar, the most usual being by means of a screw and star feed wheel.

Use of Micrometers

The most correct way to set inside calipers for boring small holes is from a pair of outside micrometers; set the micrometers to the size required, then set the inside calipers to just touch the anvil and spindle of the micrometers. The pitch of the screw threads on the spindle of the micrometer is usually 1-40 in., or 40 threads to the inch, therefore it would take 40 complete revolutions to open or close the micrometer 1 in. and one revolution will open or close the micrometer 1-40 in., or twenty-five one-thousandths of an inch. When the micrometer is closed the leveled edge of the thimble coincides with a zero mark on the sleeve and the zero mark on the thimble coincides with the horizontal line on the sleeve. Each complete revolution opens the micrometer 1-40 in. and vertical lines are placed on the sleeve 1-40 of an inch apart, each fourth line being made longer than the others and numbered 0, 1, 2, 3, 4, etc., so that each numbered line indicates 1-10 of an inch. The beveled edge of the thimble is divided into 25 equal divisions numbered from 0 to 25, so that when the thimble is moved from one line to another, the spindle is moved in or out 1-25 of 1-40, or one-thousandth of an inch.

To read the micrometer, multiply the number of vertical divisions visible on the sleeve by 25 and add the number of divisions on the thimble from 0 to the line which coinsides with the horizontal line on the sleeve. For example, the micrometer in Fig. 48 shows 9 divisions visible on the sleeve; multiply this by 25 equals 225, to this add the number of divisions shown on the thimble, which is 5. The micrometer, therefore, is open at 230 thousandths, or .230 in.

Reading the Vernier

Readings in ten-thousandths of an inch are obtained by an application of the Vernier, the invention of Pierre Vernier, this method of measurement being adaptable to any standard of measurement. As applied to a micrometer it consists of ten divisions on the sleeve which occupy the same space as nine divisions on the thimble and as each space on the thimble represents .001 in., each space on the sleeve will represent 9-10 of a thousandth, so that the difference between the lines will be 1-10 of one-thousandth of an inch.

To read a ten-thousandth micrometer, first note the thousandths in the ordinary way, then observe the line on the sleev which coincides with a line on the thimble, the first line is marked and is the starting place; if the second line marked 1 coincides with a line on the thimble,

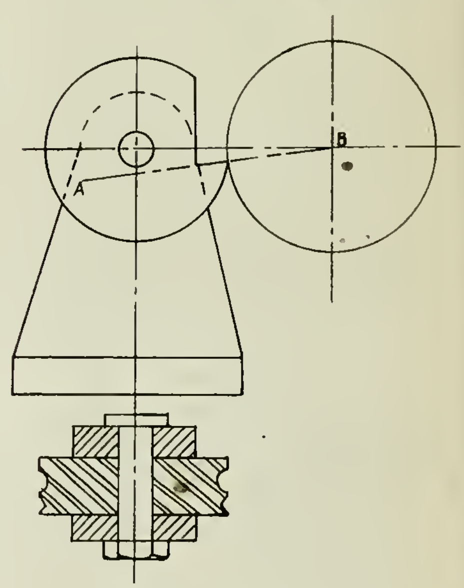

FIG. 50.

add one ten-thousandths; if the third line, marked 2, add two ten-thousandths and so on. See Fig. 49.

Types of Forming Tools

Many kinds of repetition work can be most economically done by forming tools, which are made in great variety, from the simplest radius tool, to very elaborate ones. The type and method of making depends largely on circumstances.

If there is not a very great quantity

of any one article, an ordinary lathe tool filed to a carefully made template will suffice. If the article being turned is made every day, then a more permanent forming tool can be made. A common form for an ordinary cross-slide lathe is the circular forming tool, consisting of a round piece of tool steel turned and formed so that when a section is taken at its cutting edge, it will be the shape of the work. A piece is cut out of one side of the cutter so that the edge AB is below the centre of the cutter Fig. 50.

The amount that the cutting edge is below the centre of the cutter varies with the diameter of the cutter, on a cutter 3 in. dia. about 5-16 in. being sufficient. The holder is made high enough to bring the cutting edge of the cutter opposite the centre of the work; if the tool is not set as described it will not have clearance and can only cut as long as it is absolutely sharp. Another kind of forming tool is straight-faced, being shaped or milled along the front edge to the desired form with a dovetail at back to fit some kind of block for holding it in position. They are set in the holder at a slight angle to give the proper cutting clearance, are very rigid, and can be ground a great number of times, retaining their original form as long as they last. Still another type suitable for broad surfaces is the draw cut, the tool is not square across the cutting edge, but is made at an angle, so that when the tool is faced against the work, the full breadth of the tool is not cutting at the same time, one part of the tool having finished its work before the other part begins. Tools of this description have been frequently illustrated in connection with munitions manufacture and are almost exclusively used for turning the copper bands on shells.

USEFUL MILLING JIG

By W. G.

THE fixture described herewith shows a quick and cheap method of milling clearance angles on double-sided boring and facing tools; furthermore (assuming average care be used), it has the advantage of producing a far more accurate job than is the case by ordinary methods. A glance at the accompanying

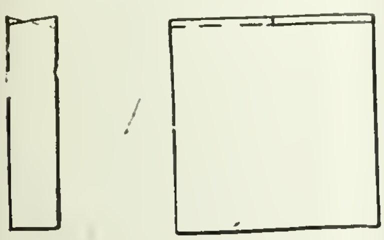

FIG. 1.

drawings will give a clear idea of its general construction. Fig. 1 shows work in finished stage. Fig. 2 shows part sectional elevation and plan views of the fixture.

The body A consists of a rectangular cast iron block of channel section, having at its extremes feet or projections, A^1 and A^2, for securing it to the ma-

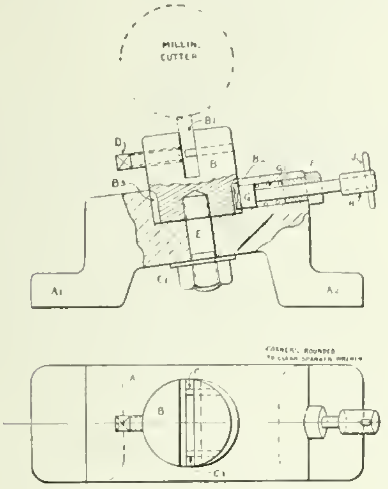

FIG. 2.

chine table. It will be noticed that the upper face of the said casting is provided with a circular recess set over at an angle; for all ordinary purposes this angle need for exceed 6 deg., as this governs the clearance on the tools. Part B is the work holder; this consists of a circular mild steel block, having a tapped hole at its lower end, the opposite end being provided with a rectangular slot B^1 for the purpose of receiving the work; it is also provided with two rectangular indexing slots, B^2 and B^3. Parts C C^1 and D are the locating pegs and clamp screw respectively. Part E is the clamp stud for holder; this should be made a tight fit for the tapped hole in the base of the work holder. Part E^1 is the clamp nut.

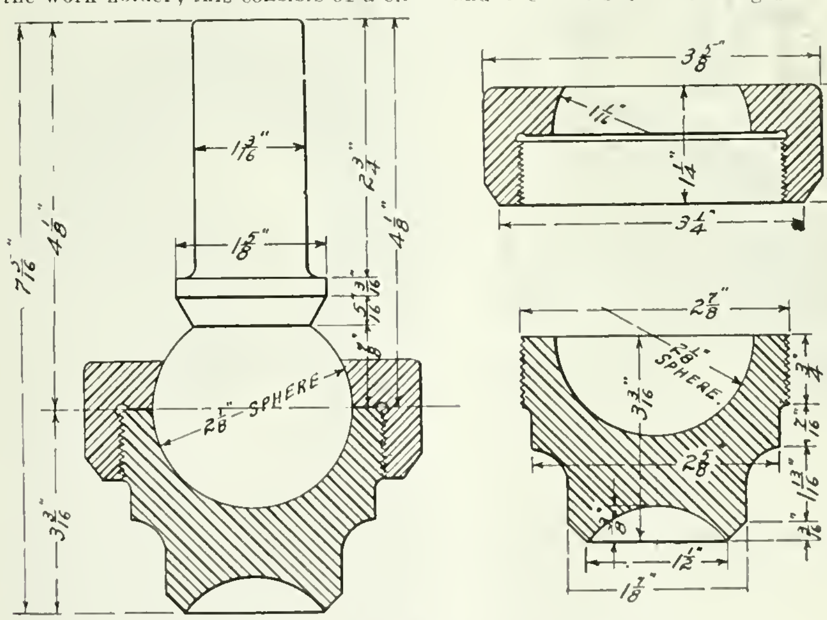
Indexing is carried out by means of the plunger G, the front end of which is provided with flats for the purpose of engaging the corresponding index slots, B^2 and B^3. Part F is the retaining bush for the spring G^1. It has been found from practice that a plain bush tightly driven into a hole is quite good enough for all ordinary purposes, as the only pressure it has to withstand is that of the index spring; and, further, being plain, the hole in the bush is more liable to be in proper alignment with that in the body than would have been the case had the bush been threaded. Parts H and J are the cap and "tommy" peg for index plunger.

The sequence of operations is as follows:—The work is placed between the locating pegs C and C^1 and clamped by means of the screw D. The side face of the milling cutter is set quite central with the work holder. The first cut is now taken over one side of work, the nut E^1 is released, and the index plunger withdrawn; a half turn of the work holder B brings the unmachined part of the work into position for its final operation, the result obtained being as shown by Fig. 1.

ADJUSTABLE RIVET SNAP

By E. T. S.

THE tool illustrated represents one of the many contrivances that lighten a job when an awkward corner is encountered. Every boiler has a firehole, and the rivets in the flanges are most awkward to rivet up on account of the small space wherein to hit direct. With this tool, the snap is set to the desired angle and tightened up, then the riveting is proceeded with in the regular manner, with the air hammer. The ball adjustment feature is a great advantage as it allows each man to set it according to his own height, and according to the position in which the boiler is placed. It is necessary to temper the shank end lightly to prevent swelling up, and of course the snap end is tempered as usual.



DETAILS OF ADJUSTABLE RIVET SNAP.

CANADIAN OIL PROSPECTS.

OIL possibilities in Canada are discussed in a statement just issued by the St. John, N.B., Board of Trade, which says:—

"New Brunswick possesses a valuable asset in its oil shales deposits. One of the best English authorities on oil, Sir Boverton Redwood, who made an exhaustive survey of this deposit, two years ago, reported that the New Brunswick shale was capable of producing thirty-three Imperial gallons of crude oil per ton of shale, and sixty pounds of sulphate of ammonia. It is estimated that a plant with a capacity of 1,500 long tons per day can retort 547,500 tons per annum, equaling 18,000,000 Imperial gallons of crude oil and 13,687 tons of sulphate of ammonia. The oil may be divided as follows: Gasoline, 2,137,500 gallons; illuminating oil, 7,951,500 gallons; lubricating oil, 2,565,000 gallons, fuel oil, 1,710,000 gallons; paraffine wax, 6,120,000 pounds; coke, 1,530 tons.

This distillation estimate is based upon the old method. By some of the newer methods it is claimed that the New Brunswick shale oil will produce more than three times the above quantity of gasoline per ton. It is believed that there is already sufficient shale available to operate for fifty years at least five plants of the capacity of the one above proposed. The New Brunswick shale is said to be of much better quality than the shale of Colorado, and the quantity is greater. The geological authorities at Washington, recognizing this fact, have been devoting considerable attention to the New Brunswick deposit. Increased development in connection with these deposits is looked for within the next few months."

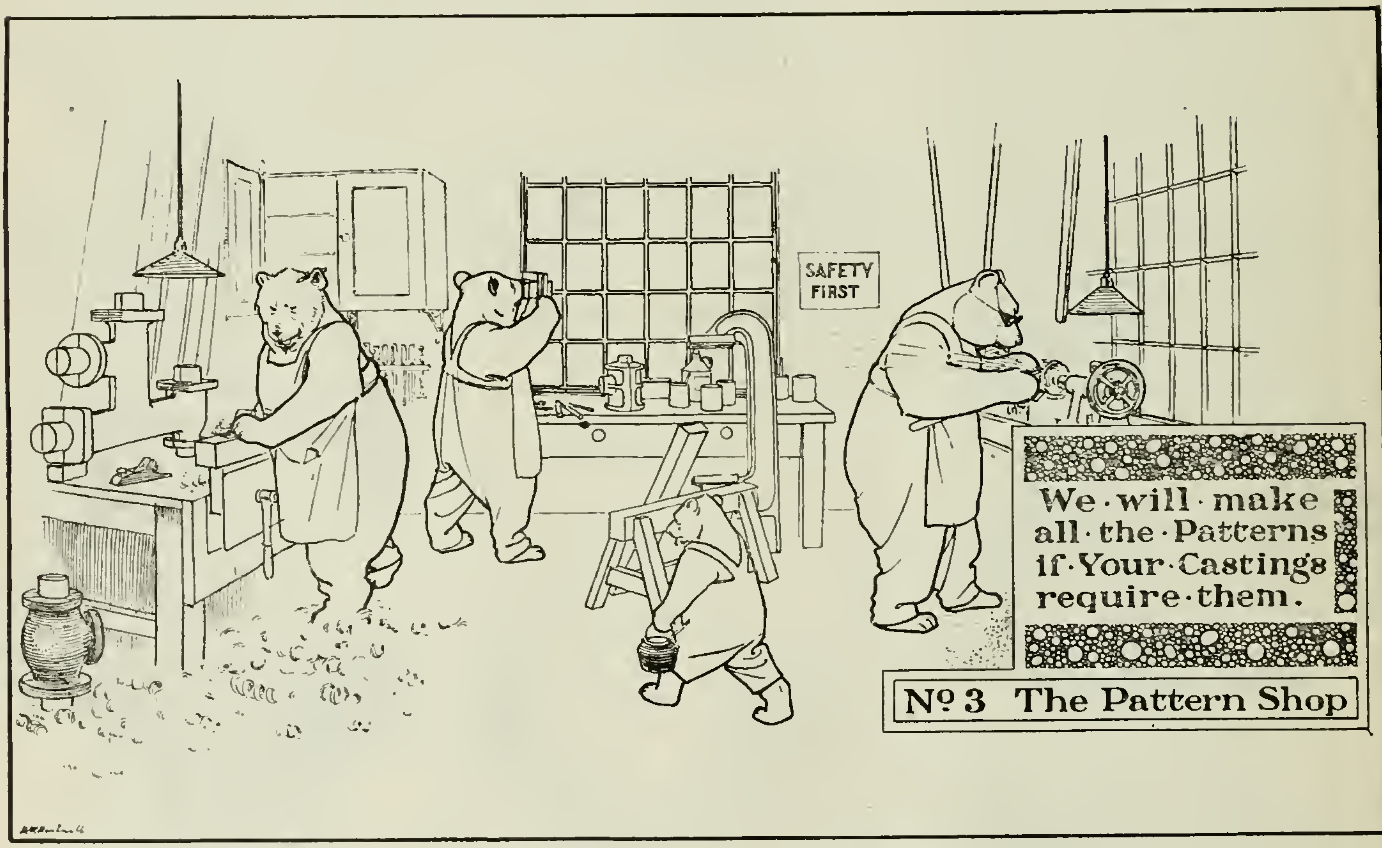
RESULTS FROM UTILIZATION OF COAL

AN English writer recently pointed out that there is something more to be got out of coal than smoke, ash and a low percentage of its power and heat. He estimated that in British mines alone there are left annually 115 million tons of dross or slack or unworked coal in friable or unprofitable seams. Half of this is said to be sufficiently rich in hydro-carbons to be suitable for conversion in recovery plants, with the following results: Slack and dross available, 57,500,000 tons; benzol, at 2½ gals. per ton, 143,000,000 gals.; Diesel oil, at 1 gal. per ton, 57,000,000 gals.; sulphate of ammonia, at 25 lbs. per ton, 640,000 tons; coke, at 10 cwt. per ton, 28,700,000 tons.

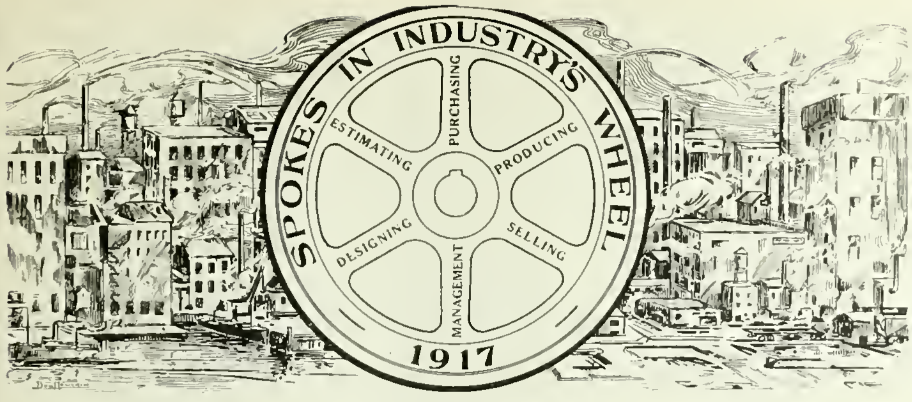
INTERNAL COMBUSTION ENGINE LUBRICATION

IN the vertical type of internal combustion engine, it is absolutely essential, in order to secure a distribution of the lubricant around the cylinder bore, to supply the oil through a number of feeds, as many as four per cylinder on the smallest sizes and more on larger diameters. A horizontal cylinder, on the other hand, even of the largest size that is practicable to build, can be effectively lubricated over its whole surface from a single feed on the upper side. Gravity helps to distribute the oil.

In any internal-combustion engine, some of the lubricating oil is carbonized. In a vertical engine this carbon tends to work down past the piston, fouling the rings and dropping into the crank pit, where it becomes mixed with the bearing oil. In the horizontal type, much of this carbon is pushed into the counterbore, whence it can be removed through a blow-off valve in the bottom of the cylinder. Such portion as works past the piston can be caught in the frame and prevented from mixing with the bearing lubricating oil. Even the main bearings in a horizontal engine are more effectively lubricated. During the working stroke, when the pressures are highest, the main shaft is partly lifted from the bottom shell, allowing the lubricant to fill the space; again, on the two idle strokes, the exhaust and inlet, inertia effects tend to bring the shaft first against one side of the bearing, then against the other, thus effecting a very thorough distribution of the oil.



BUSINESS ENTERPRISE IN CARTOON—NO. 3 OF A MONTHLY SERIES APPEARING BY COURTESY OF CANADIAN STEEL FOUNDRIES, LTD., MONTREAL AND WELLAND.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

WILLIAM CASEY

"LOCOS come and locos go, but Casey keeps right on the job"! The foregoing is not exactly as Tennyson has it, but is expresses the popular sentiment among the numerous friends of William Casey, manager of the Canadian Loco. Company's works at Kingston, Ont. The transient character of the product is in direct contrast to that of the subject of these remarks; born and educated within earshot of the plant—October 13, 1887 was the eventful day—Bill experienced all the thrills and joys incidental to a boyhood admiration for, and ultimate acquaintance with locomotives. As the chief industry of the city, the Locomotive works were the Mecca of all ambitious youths with a bent toward mechanics, so. after acquiring all the available knowledge at St. Mary's School and Regiopolis College—local educational institutions—our subject entered the service of his present employers in the capacity of office boy.

The lure of the locomotive, however, did not allow him to remain a distant admirer very long, and Bill was soon making himself at home in overalls and getting on terms of intimate acquaintance with fireboxes, blast pipes, crossheads, cranks, and headlights. This sound basis of his present position was supplemented by a term in the drafting room studying the whys and wherefores and also the "ought to be's". That his opportunities for absorbing information had been turned to good account was evidenced by his appointment as machine shop foreman in 1907 at the comparatively youthful age of twenty years, his ability to direct the efforts of subordinates being amply demonstrated during the five years tenure of this position.

From this time, it would seem that the cumulative effect of all Mr. Casey's previous experience was to point to him as "the man," when any "higher up" position became vacant, the result being that in 1912 he became responsible for all piece work administration and estimating work.

Developments and opportunities succeeded each other rapidly. In 1914, he became assistant to the then vice-president and general manager, (A. W. Wheatley), and in this capacity went through all the strenuous times of munitions production in the early days of the

WILLIAM CASEY.

war. Not that the early days were the only strenuous times by any means. The legitimate resources of many Canadian factories were of very great value to Britain and her Allies, and the production of locomotives, which had declined very considerably after the outbreak of hostilities, was soon resumed with great vigor, record orders, rapid production, and repeat contracts having been the rule for many months now. The production of a staple line of machinery, to foreign specifications, dimensions and inspection, in rush time, along with shells of various sizes both machined and rough forged, in rusher time indicated a degree of managerial ability which convinced those in authority that talent of no mean order was available when occasion required. It was a matter of general expectation therefore, that as the result of administrative changes done to the resignation of Mr. Wheatley, Mr. Casey should become manager of the Canadian Locomotive Co., the well earned and popular promotion taking place in the early part of last year.

In view of the entrance of the Co., into foreign fields, considerable hopes are entertained regarding future developments in this direction, the bonds of sentiment and mutual interest engendered by the present struggle being likely to prove a factor of some importance and in this respect Mr. Casey's life long association with the Co., will go far to insure a continuance of the good will and international reputation now enjoyed by the concern.

To say that the locomotive works are Kingston is just as much a truism as that Kingston is the Locomotive works, and while Mr. Casey's activities preclude any great political activity, the field for civic effort would seem to hold much promise for the future.

BOILER INSPECTION AT MONTREAL

ALTHOUGH his annual report is a year behind, boiler inspector E. O. Champagne is once more able to inform the public that for the year 1915, no boiler explosions occurred in Montreal. This long immunity from serious boiler accidents has been a feature of Mr. Champagne's reports for many years, and in that connection a letter of congratulations is quoted from the Travellers' Indemnity Company of Hartford. The following is the record for steam boiler inspection for 1915:

Visits of inspection	3,112
Internal and external examinations	1,889
Hydraulic tests	1,621
Hydrostatic tests	606
Imperfect boilers	203
Boilers condemned	4
New and second-hand boilers erected	77
New boilers (included in this number)	65
Notices of inspection issued and received	922

The licenses issued to engineers and others after due examination to take charge of steam boilers was 2,255. Those who failed to pass examinations numbered 127.

Visits made in connection with new devices for smoke abatement were 767

WORLD SHIPBUILDING DURING 1916.

THE outstanding features of the world shipbuilding statistics for 1916, are the decrease in production in the United Kingdom and the great activity in the United States. British shipyards have been so busily employed on naval work that they have done even less merchant work than in 1915, while shipbuilders in the United States have been experiencing a great boom in new contracts, many of them from neutral countries who were good customers of the United Kingdom in pre-war years.

The English, Scottish, and Irish production consisted of 412 merchant vessels of 582,305 tons and 410,281 i.h.p., compared with 517 vessels of 649,336 tons and 540,594 i.h.p. in the previous year—a decrease of 105 vessels, 67,031 tons, and 130,313 i.h.p. It is however, necessary to go farther back than one year in order to find how the work compares with that of normal times. It is less by 882 vessels, 1,139,849 tons, and 956,553 i.h.p. than that of 1914—in which five months of the year was disturbed by the war.

Warship tonnage and all other tonnage built to the order of the British or Allied Governments is excluded from these figures, and the general result is that in 1916 there was launched about one-third of the tonnage of 1914. Going back to the purely mercantile output of 1913, we find United Kingdom totals of 1424 vessels, 1,977,573 tons, and 1,556,560 i.h.p.—not far short of four times those of 1916.

These comparisons are eloquent of two things—(1)—The amount of work of a non-mercantile character that has been done, and (2), the amount of reserve power that will be released in British shipbuilding when the war is over. It would, the writer continues, certainly be a great mistake to infer that they indicate any falling off in producing capacity. Behind them there is a period of unprecedented activity, works extensions, and improvements in plant and in organization that will be invaluable assets to the industry when the war is over, and experience which has proved that those who thought that British shipbuilding had come in 1914 within sight of its limit in productive power had very little idea of what it could really do.

In the foreign production there is an increase from 989,337 tons to 1,335,791 tons. This increase is accounted for almost wholly by the work done in America and Japan. In the United States the production was more than double that of 1915, while from every district there came reports of many contracts and extreme activity. The yards on the Great Lakes did a large amount of work, whereas in 1915 they had a very low tonnage to their credit. In Japan the total was almost three times that of 1915, the increase being accounted for principally by the construction of a good many large cargo steamers. In Holland, shipbuilders were working under exceptional difficulties, and one firm stated in their report that, owing to the increasing difficulty of obtaining materials, stagnation in their industry was threatened. There were few reports of launches in Germany, and in other Continental countries there were no features of outstanding interest.

MERGE RAILWAYS INTO ONE SYSTEM

IN a paper presented to the Canadian Society of Civil Engineers, recently in Montreal, W. F. Tye dealt with the subject of "Canada's Railway Problems." After giving many figures showing the history of railway development in Canada and the manner in which money had been squandered duplicating roads, Mr. Tye suggested as a solution that the Government authorize the organization of a new corporation to take over the Grand Trunk, Grand Trunk Pacific, National Transcontinental and Canadian Northern railways, and consolidate them into one comprehensive system.

This, he suggested, should be run by the corporation, without any Government interference in the management, although he proposed that the Government should own at least 40 per cent. of the stock and have a proportionate representation in the directorate. With this plan he showed a series of maps and diagrams, indicating the manner in which he considered such a consolidation would do away with overlapping, and permit of the doing away with a lot of the duplication of tracks which was now in existence in both Eastern and Western Canada.

The Grand Trunk Pacific, he said, had a splendid main line, built on altogether too expensive a plan for the traffic. The Canadian Northern had a poor main line, while it had a good supply of feed lines, which the G.T.P. had not. In the east the Grand Trunk supplied a splendid line of feeders, while the Canadian Northern and National Transcontinental would supply an excellent main line and in many sections overlapping parts could be done away with.

His proposition was that by taking the four lines and doing away with as much as possible of the losses caused by extravagant Government finance, overlapping of roads, and other mistakes, and getting the lines into a reasonable condition of efficiency, the mistakes of the past might eventually be overtaken. He proposed that the four lines should be put into a holding company, and, if necessary, the G.T.P. and Canadian Northern liquidated, so as to get on to a firm basis for a start.

It would probably then, he considered, be necessary to spend a large amount during the next five years improving the existing lines and building feeders, but by that time he figured that the increase in business would be such that from a steady loss during the first few years the consolidated railroads would get to a paying basis, probably within five or six years. Mr. Tye put it that the C.P.R. had been a great financial success, the G.T.R. a moderate success, the Canadian Northern a moderate failure, and the G.T.P. a great financial failure.

The C.P.R. had succeeded by wise planning, wise aid and good management, but Government ownership could never succeed on so vast a plan as that he suggested for the consolidation of the four roads, hence his suggestion for the formation of a company, with stock guaranteed by the Government, which would put it on a 5 per cent. basis. In this way they would avoid the costly experience of the Intercolonial. With the amount of land available, and the possibilities of business he did not see how there could be a failure of such a business consolidation of railways.

The whole situation, he said, had arisen through unwise duplication of railways and a vicious system of bonusing and land granting, which should be stopped. That would end the debauch of railway construction from which Canada was now suffering.

HYDRAULIC RESOURCES AND INDUSTRY

IN estimating the value of Canada's hydraulic resources and their importance with reference to future industrial development, the extent to which electro-chemical processes have entered into some phases, at least, of nearly every branch of our industrial life is not generally appreciated.

A small beginning in electro-plating, two generations ago, has developed until the great bulk of the copper output of the world is electrolytically refined. The electrolysis of common salt is the basis of the electrolytic alkali industry, the products of which are caustic soda, metallic sodium, chlorates, and hypochlorites. The electric furnace has created a host of new industries, producing chiefly abrasives, graphite, silicon, ferro-alloys, refined steel, phosphorus and calcium carbide. It has also been tested experimentally as a competitor of the combustion furnace in the metallurgy of many metals.

Used as an electrolytic furnace, we have the very important application to the production of aluminum. The industrial use of electric discharges through gases is still in its infancy, but we have ozone and nitric acid among the products, the former used for sterilization, and the latter as a basis for fertilizers and explosives.

Every one of these industries consumes large quantities of energy. Whereas the refining of lead requires only 120 k.w.h. per ton, we have consumptions as high as 4,000 k.w.h. per ton for other metals. The aluminum furnace requires 25,000 k.w.h. per ton of product.

The electro chemical industries have grown to be of great value to countries which possess good opportunities in water power resources, as they have a fundamental interest in the development of cheap power.

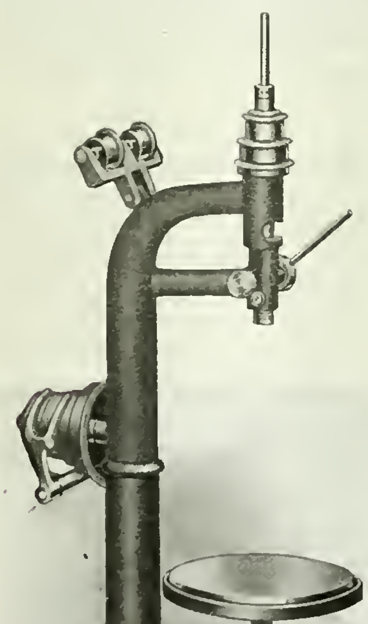
PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

COLUMN SENSITIVE DRILL PRESS

THE illustration shows a floor type of sensitive drill having a capacity up to ½ in. recently produced by the DeMooy Machine Co., Cleveland, O. This machine is also made in a bench type in which the table arm is hinged on the column close to the cone pulley. The high carbon steel spindle has long bearing support, the lower bearing being provided with additional support by a brace from the column. Steel, fibre, steel thrust bearings are used, and a No. 1 Morse taper is provided in the spindle.

Spindle speeds up to 2,000 rev. per min. are obtained, the shaft which carries the belt pulleys and the two-speed cone pulley projecting directly from the column and carrying the belt shifter direct from its outer end. This arrangement enables the belt shifter to be pivoted around the pulleys to suit any desired angle of drive.



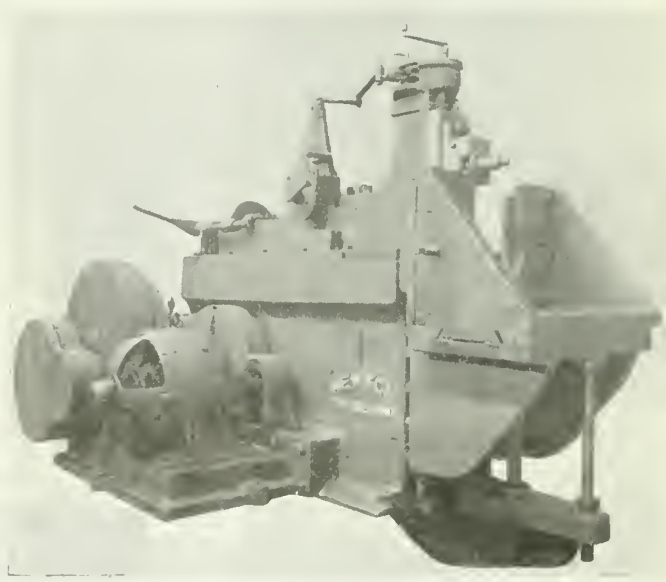
COLUMN SENSITIVE DRILL PRESS.

The net weight of the machine is 110 lbs. in the bench type, which, along with the floor type has the following leading dimensions: Greatest distance spindle to table with table arm up, 12 in.; vertical movement of table, 7 in.; centre of spindle to frame, 7½ in.

SPECIAL TYPE SHAPING MACHINE

AN interesting shaping machine of specialized design arranged for the performance of one specific operation has been built by the Newton Machine Tool Works, Philadelphia. The machine is of very massive construction, weighing 30,000 lbs. and having a stroke of 30 in. The distinctive feature of this machine is the provision of power vertical feed, operated by a pawl engaging an incline which insures an accurate definite amount of feed at each stroke.

Heavy box type construction is adopted throughout, while the drive is similar to that used on crank slotting machines, through connecting rod and Whitworth motion from the motor giving a quick return stroke.



EXTRA HEAVY 30 IN. SHAPING MACHINE FOR MACHINING LOCOMOTIVE BOXES.

The table is of special design for holding steel locomotive boxes while machining the collar fits, the arrangement adopted serving to increase the visibility of the markings to be worked to. Hand elevation is provided for the knee, as is also a slight amount of hand cross adjustment to the angular table to which the boxes are bolted.

This machine, similarly with another having a circular feed, is driven by a 15 horse-power motor having a speed of from 400 to 1,200 rev. per min.

GAS HOLDER INSTALLATION

CONSIDERABLE interest attaches to the new gas plant recently installed by the city of Sherbrooke, Que., at a cost of about $100,000, the gas holders being the first to be designed and installed by Canadian engineers. These were built by the Jenckes Machine Co., Sherbrooke, under the supervision of Wm. Rodger, chief engineer, the water gas plant which forms part of the equipment having been installed by the Western Gas Construction Co., under the supervision of D. J. Sweeney.

Although the fact that coal would yield an illuminating gas, was known long before that date, it was not till 1792 that William Murdoch discovered a process for manufacturing gas from coal, and in 1798 he successfully applied his invention to the lighting of his residence in Old Cumnock, Ayrshire, Scotland. Many improvements and developments in manufacturing equipment have since taken place, the Sherbrooke water gas plant is representative of the latest and best practice, the necessity for efficient operation being evident when it is stated that any want of economy in the first stage cannot be compensated for in any of the later stages of the process.

Coke is the material from which the gas is obtained by means of generators, being then enriched by oil for the purpose of increasing its luminosity, the resulting gas then passing successively through scrubbers, condensers, and tar extractors, into a small relief gas holder, after which it is passed through ammonia washers and purifiers till it reaches the large gas holder shown in the illustration.

The generators into which the coke is first deposited are two in number, 11 ft. 6 in. high by 5 ft. dia. of cast iron construction and double lined to a thickness of 10½ in. with heat insulating material, the inner 6 in. being a special grade of firebrick. The carburetters, of which there are also two, are 12 ft. high by 4 ft. 6 in. dia. of similar construction to the generators, and are filled with chequer bricks so arranged as to form a series of baffles to the gas. At the top of the carburetter, heated oil is sprayed in the form of a mist which commingles with the gas from the generator.

The gas is made by passing steam at 100 or 120 lbs. pressure into the bed of incandescent coke in the generator, thereby decomposing it into its constituent gases, oxygen and hydrogen, the former

70 FT. DIA. GAS HOLDER OF 200 000 CU. FT. CAPACITY AT SHERBROOKE, QUE.

combining with the carbon of the coke to form carbon dioxide, which, rising through the upper layers of the incandescent coke is reduced to carbon monoxide; this last gas finally combines with the free hydrogen forming what is known as "blue gas". Blue gas is non luminous and is therefore enriched with oil in the carburetter so as to possess light giving properties.

The process of manufacture can be continued as long as the fuel in the generator is sufficiently high in temperature to reduce the carbon dioxide to the monoxide. Usually a period of six or seven minutes generation causes the temperature of the fuel to fall too low for this action to continue; the steam and oil are then shut off and an air blast turned into the generator, which in three or four minutes restores the coke to the desired temperature when the cycle of operations is repeated.

Two water sealed scrubbers each 19 ft. 8 in. high by 3 ft. 6 in. dia. receive the gas from the carburetters, after which it passes into condensers 19 ft. high by 3 ft. 6 in. dia. having sixty-one 3 in. tubes, 16 ft. long. Tar removal is the next process, being done in extractor tanks 5 ft. by 5 ft. by 12 ft. long, passing thence into a relief gas holder of 30,000 cu. ft. capacity, having a diameter of 45 ft., and a height of 19 ft. In order to overcome the pressure caused by the resistance of the ammonia washers, the gas is drawn from the relief tank by two Root exhausters, one geared to a 2 horse-power constant speed a.c. motor, and the other direct connected to a vertical steam engine. These machines force the gas through the washers in which it is arranged to bubble upwards through the washing liquid. As the gas rises, it is caught by a perforated screen which sub-divides the particles into a fine foam, the screens being so constructed that the solid matter, precipitated from hard water, will be washed off and drops to the bottom of the washer, at the same time avoiding excessive back pressure due to stopping up.

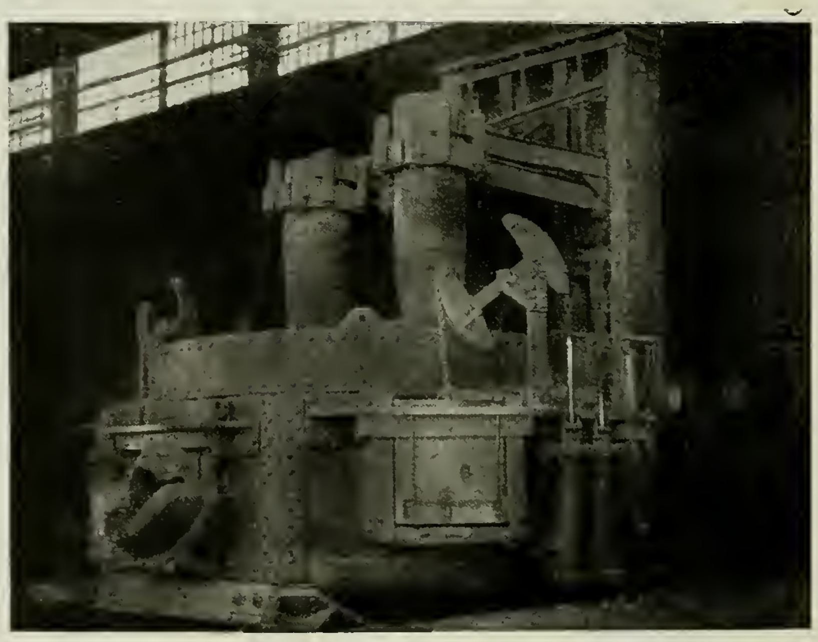
The final stage is purifying which is done in boxes, 11 ft. 6 in. dia. by 12 ft. deep, after leaving which the gas passes through the meter to the large gas holder, which serves the all important purpose of equalizing the distribution of gas under pressure and insures an unbroken supply so long as any gas remains in it. In form it is cylindrical, with the open lower end submerged in a tank allowing it to work up and down freely. It is guided in its vertical movement by rollers which work against guide rails attached to the columns or standards. It has a capacity of 202,000 cu. ft. and is of telescopic construction in two lifts; the inner lift is 70 ft. 8in. dia. by 25 ft. 6 in. deep, and the outer lift is 72 ft. 7 in. dia. by 26 ft. 1 in. deep. No counter-weights are required in connection with the holder as a result of the use of exhausters and governor.

The crown or roof of the holder is untrussed as the top curb is of sufficient strength to resist distortion by the pressure of the gas; a wooden frame work, however, was erected inside the tank to support the untrussed roof when the holder rests empty on steel landing beams. The main standards are made of steel I beams extending 54 ft. above walk of tank and are tied together midway and top by 24 in. deep lattice girders, diagonal wind ties of round and flat bars imparting increased rigidity to the frame. The tank containing the water into which the holder telescopes is 75 ft. dia. by 26 ft. 3 in. deep, and is built of steel plates having a walk round the top reached from the ground by stairway, while a ladder extends to the top of the standards, the height from the ground level to this point being 80 ft.

The plant described has a capacity of 16,000 cu. ft. of gas per hour.

ELECTRIC FURNACE EQUIPMENT

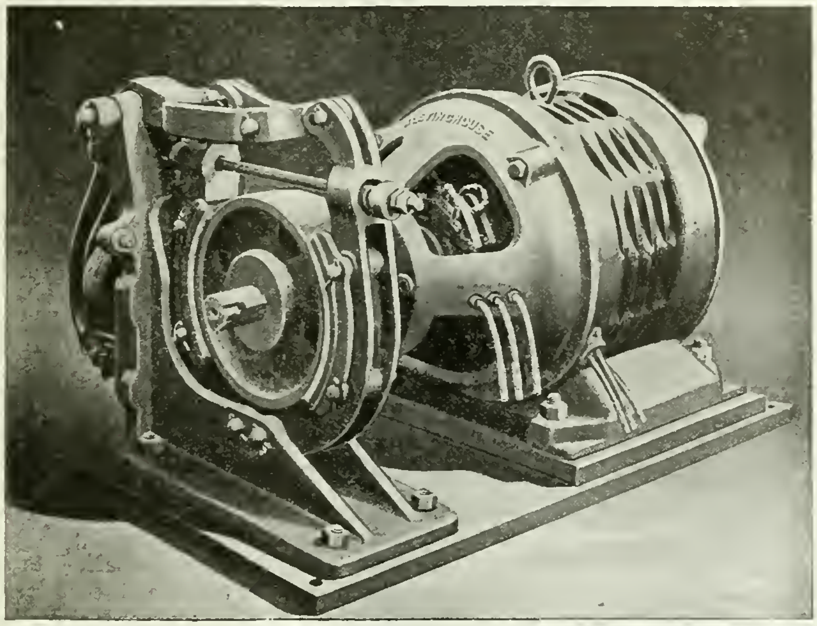
THE constant broadening of the commercial field of the electric furnace is due largely to the perfecting of furnace design and reduction in cost of power. Whereas their former use was principally in the refining of high grade alloy and tool steels, they are now being more widely used for the refining of common grades of steel. Improved devices for charging and tilting, larger electrodes,



ARC TYPE ELECTRIC FURNACE SHOWING ELECTRODES, CHARGING AND POURING DOORS.

and automatic regulation all tend to greater economy.

While many different designs of furnace are in existence, they can be grouped in two general classes, the induction furnace and the arc furnace; the latter, in sizes from one-half to 20-tons having been adopted almost exclusively in American practice.



TILTING MOTOR WITH BRAKE GEAR AS USED ON ELECTRIC FURNACE.

The Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., has developed complete electrical equipments for all classes of furnace, that for the arc type of furnace, assuming high tension alternating current is available, including line protective equipment, switchboard, step down transformers, furnace tilting motors, motors for adjusting position of electrodes, and a regulating system for the control of the electrode motors.

The type of motor employed for operating the tilting mechanism is shown in one of the accompanying illustrations. Either a.c. or d.c. motors are suitable, having characteristics similar to those used for hoisting work. The controller is of the reversing type and a motor brake is used to prevent over-travel of the furnace and hold it in any desired position, a complete line of motors from 15 to 150 horse-power being available for this work.

Where automatic control of the electrode is desired, a motor operated hoisting mechanism is provided for each electrode. As the motors are mounted on the furnace which tilts, the bearings are built with special lubricating features. Shunt-wound direct current motors are selected for this service, enabling a more simple and positive system of control to be used than when alternating current is used.

Automatic regulation has as its object the maintaining of a constant current at the furnace resulting in higher furnace efficiency and increased output of higher and more uniform quality. The Thury system has been adopted for a large percentage of the furnaces in use, and can also be adapted for maintaining a constant potential when desired. A three phase furnace equipment is illustrated herewith and consists of three regulating drum controllers; three field regulators; three resistances, two series transformers, and one motor with shafting etc.

Damping devices permit the regulator to act only when necessary, and sudden changes and peaks of short duration do not put the regulator in action. This in itself is very important, as there is not only a great saving in the wear and tear of the electrodes hoisting mechanism, motors for driving same, etc., but the current is kept more uniform by avoiding unnecessary regulation.

Each regulator controls one electrode. The regulator is controlled by a solenoid energized by means of current from series transformers in the main high tension circuit. The regulator in turn controls the armature circuit of the electrode motor to give it motion in either direction, or stop it, as required. This electrode motor operates a hoisting mechanism, which in turn raises or lowers the electrodes. The regulator can handle any amount of power for regulating purposes without impeding the free play of the controlling mechanism, which is only in contact with the power mechanism for exceedingly short periods of time and is otherwise perfectly free. Intermittent action of a contact making arm prevents the regulation from being carried too far in one direction. Thus a high load power factor and a uniform current on the furnace is assured at all times.

Wireless Emphasis.—She sailed into the telegraph office and rapped on the counter. As the clerk came forward to meet her he remembered that she had been there about ten minutes before. He wondered what she wanted this time.

"Oh," she said, "let me have that telegram I wrote just now; I forgot something important. I wanted to underscore 'perfectly lovely' in acknowledging the receipt of that bracelet. Will it cost anything extra?"

"No, ma'am," said the clerk, as he handed her the message.

The young lady drew two heavy lines beneath the words and said—

"It's awfully good of you to let me do that! It will please Arthur ever so much."

OUR MUNITIONS MANUFACTURING OUTLOOK

NOTWITHSTANDING the now well-established fact that peace in Europe will be consummated through victory, and that it has been determined to the fullest extent possible to meet the multitudinous equipment requirements of our armies in training and in the trenches by the utilization of Empire labor and material resources, some misgiving appears to prevail concerning Canadian munition contract renewals covering the third and fourth quarters of this year. Few people, however, are to be found who are in the least degree sanguine as to a cessation of hostilities during either period. For misgivings under any circumstances, there are usually—we might say always, reasons or causes, substantial or imaginative. Without, however, seeking to probe these too deeply, may we point out—aside from a "Peace with Victory" development during the present year, a few facts relative to the production of munitions for Empire requirements generally.

We are apt at times to forget that our activities are for the accommodation of the Imperial Government, and that the placing of munition orders—quantities of shell of variety, type and size, is not an indiscriminate proceeding and based wholly on a reckoning that, if there be available a good supply of each type and size, all will be well. This war, irrespective of its numerous shortcomings in prosecution, is being engineered, and, as might therefore be expected, is exemplary of much sound scientific management. We are probably right in saying that up to January 1 of the present year, shells called for in Canada have been based on three monthly periods, at the end of which, quantities, types and sizes further required were liable to differ materially and have actually done so, although maintaining the type and size ranges prevalent.

When this feature of the situation is fully appreciated, and especially so its engineering or scientific management aspect, the reasons for such a line of action are not far to seek. Stated briefly, any three months' experience in the field determines the suitability or effectiveness of the munition detail employed, and, as we see it, can hardly fail to influence materially the quantity, size and type of shell when orders come to be placed in the succeeding quarter. Again, isn't it reasonable to assume that requirements more or less immediately antedating a big offensive will find expression in shell contract detail distinctiveness.

Canadian metal-working plant executives are in a number of cases worrying as to their prospects for renewal orders after June 30 of this year, at which date we understand all existing contracts expire. This is perhaps not an unnatural state of affairs. In our estimation, however, we are yet well beyond five months removed from the cessation of quantity and variety shell orders, and consequently from peace-time commodity production.

As bearing out our views, it may be noted here that in the past twelve months much switching took place relative to the constitution of shell orders placed in Canada, and our anticipations are that the next new period contracts will but witness action more or less similar in its scope and effect to that experienced in the past. The switching from one type or size of shell to that of another is to-day less irksome, both from the equipment and operator viewpoints, for equipment is not only more readily available than say a year or so ago, but is more efficient for its purpose. The experience of the operator is also such as to make him tackle confidently the production of shell other than those on which he has been for the most part engaged. While it may be said that "Peace with Victory" is appreciably nearer than "Peace without Victory," its imminence is not, we make bold to say, such as to affect the intensive manufacture of munitions in Canada during the third and fourth quarters of the present year at least.

POST-WAR TRADE PREFERENCES

AN impression is abroad that, as a result of the Economic Conference held in Paris, France, some few months ago, the Allied Nations are committed to a hide-bound scheme whereby their trade and commerce after the war will be quite exclusive. In a word, a worthwhile preference will be made effective as regards all forms of their business intercourse. Just how such an idea originated is rather difficult to determine; this much, however, may be said, that no official statement may be cited from which to draw any such conclusion, much less that plans to that end have as yet been initiated or are in process of development. We have good reason for believing that beyond stimulating une bonne entente, the Paris Conference accomplishment is otherwise valueless.

The trouble about preference ideas being appropriated and nursed is the tendency to restriction of effort and enterprise and the disposition to make use of a business prop of questionable strength, and lean on it over-heavily. Such a state of affairs may not be wholly unknown in Canadian industry. On the other hand, prospective preferences among the Allied Countries have a stimulating effect on the business enterprise of Neutrals, arousing as it does a desire to establish themselves—parent or subsidiary plant, in favored territory. Evidence of the latter is not meantime wanting in the quest by many American industrial concerns for factory locations and sites in our midst, and their desire to glean the fullest possible information regarding after-the-war trade prospects. Much as we welcome their coming, we may not influence it on the score of assumed trade preferences following the war.

In spite of the many prophecies, eloquent speeches, discussions by representative bodies, and resolutions relating thereto, it can be stated positively that no man nor body of men have meantime the slightest idea as to conditions immediately following the war, relative to world trade and commerce, or otherwise. The only thing of importance just now, here or in the Allied Countries, is the prosecution of the war to an early and victorious finish. Opportunity in plenty will then be afforded not only to remodel the broken face of civilization, but to plan tactfully and effectively for its all-time preservation. When this work is done, trade preference vaporings may have become still air.

INDUSTRIAL NOTABILITIES

JAMES ALEXANDER McMAHON, treasurer and managing director, Union Drawn Steel Co., manufacturers of high grade cold die rolled steel and shafting, pump rods, piston rods and special shapes, special screw stock, rounds, squares and hexagons, was born in Venango County, Pa., Dec. 18, 1859, son of John and Margaret (Wolf) McMahon. He was educated at Public Schools of Pennsylvania, supplemented by a Commercial Course at Oberlin, O. He conducted a Commercial College at Beaver Falls, Penn., 1887-1892; was

JAMES ALEXANDER McMAHON

with Swan Electric Co., Cleveland, O., 1892-1893; with Union Drawn Steel Co., of Beaver Falls, Penn., 1893-1905; came to Hamilton in 1905 and established the present business.

Mr. McMahon is a member of Executive Committee, Hamilton Branch, Canadian Manufacturers' Association; member of Membership Committee, C.M.A., for all of Canada; and was chairman of Membership Committee, C.M.A., 1911, for the Dominion; member Technical Committee, Hamilton School Board; member Hamilton Board of Trade. He married Jennie G. Beegle, daughter of Benjamin F. Beegle, July 25, 1889; has one son and one daughter. His Clubs are: Commercial; Royal Hamilton Yacht; Canadian; and his Societies: A.F. & A.M. In Politics he is Conservative; and in Creed: Methodist. His residence is at 81 Barnsdale Boulevard, Hamilton, Ont.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., Jan. 29—Difficulties of transportation are probably the chief feature of interest in the industrial situation at present, the lack of sufficient facilities for handling the numerous urgent classes of freight having had a serious effect on certain trade conditions through the placing of embargoes. Weather conditions have tended to aggravate matters, particularly the coal shortage, which has made itself felt in domestic as well as industrial circles.

Pig-Iron

Pig-iron production has been affected more, perhaps, than any other allied line, through the serious coke situation, and as a result the output has fallen off. The market has not developed any special feature, but continues to maintain its abnormal strength.

Steel

Curtailment of output has followed the shortage of raw materials, resulting from the inability to obtain delivery, owing to difficulty of transportation. Car shortage and freight embargoes have tied up needed materials to the extent that some plants have been closed down temporarily, while others are operating light. Business is brisk in billets and sheet bars, and top prices are still the feature. Prompt deliveries on plates are still demanding premiums, and in some instances impossible to get even with this consideration. Owing to the heavy export of steel rails, mills are quite active on these lines. Activity in sheets is not so pronounced and mills are accepting business more freely. The stronger tendency of spelter may affect the quotation on sheets, but some little time must elapse before this becomes evident. Contracts are being placed for last half tin plate, irrespective of price, this to be adjusted at a later date. The shafting situation is showing relief, as producers are running in advance of expectations and delivery is becoming more normal. No developments are noted in the wire situation, and it is generally anticipated that prices will remain steady for some time. Iron and steel bars show a little easier, but the demand is fairly active. Boiler tubes and pipes are much in demand, consumers still being under-supplied. The local situation continues very steady, with no advances reported.

Metals

The tone of the general market is much stronger and prices show an upward tendency. The feeling is strong that negotiations may soon be opened for future metal requirements for the Allied powers and this is affecting present conditions. Copper has regained much of the recent loss. Tin is unsettled, but firm. Spelter appears stronger, while lead is higher on a speculative basis. Antimony features the market with a sharp advance. Aluminum is steady, but easier.

Copper—Copper is in a very strong position, owing to the sold-up condition of the market. It is very difficult to secure much metal for early delivery. Holders of metal are loth to part with it and the tendency seems to be for a still stronger market. Producers are practically out of the market, refusing to quote on future delivery. This attitude is due to the possibility that the Allies may soon be covering their last half requirements. The local market is active, and developing additional strength, dealers here having advanced prices ½c per lb. Lake and electrolytic are now 36½c, with castings 35½c lb.

Tin—The market is still featured by the nervousness that prevails, owing to the uncertainty of the situation, caused by the lack of information regarding tin shipments. The general situation shows little change and the strength of the market may be largely accounted for by the dangers that are prevalent in the transportation of the metal. London quotations are stronger, but New York is ¾c lower than a week ago, the present nominal price being 45⅛c per lb. The market here is fairly active and dealers have added one cent to their listed prices, quoting 48c per lb.

Spelter—The backward attitude of producers and sellers has resulted in a stronger market, but consumers are not showing increased interest in the situation, and the demand is not heavy. Present conditions have resulted from the possible requirements for export purposes during the coming months. The London situation continues steady, while New York reports of ¾c on the week, the price asked being 10¾c per lb. On a fairly good demand local dealers have advanced their quotations to 14½c, this being one cent higher than last week.

Lead—The action of independents in advancing prices would appear to indicate a stronger market, but this strength is due more to speculation than to actual conditions. While situation is very firm, the leading interests are content to hold to their present prices, realizing that little is to be gained by forcing the market at this time. The trust price holds at 7½c, while outside quotations have advanced to the nominal figure of 8¼c per lb. The market here has been quite active and dealers are quoting 10½c, an advance over last week of ½c.

Antimony—The apparent scarcity of antimony and the small quantity available has resulted in a sharp advance in prices asked. The curtailment of output from some of the Chinese refineries is also affecting the situation. The advance on the New York market is about 6c per lb., the nominal quotation being 21c per lb. The market here is strong and dealers are asking 18c, an advance of 2c on the week.

Aluminum—Market quiet and unchanged, prices easy at 70c per lb.

Machine Tools and Supplies

Business is not over-active, but sufficient volume is passing to maintain the interest of the trade. The manufacture of munitions has reached the stage where orders for bulk equipment have been largely filled, and dealers can only report sales of single or small lots of machinery. In some localities brisk business is being carried on in the manufacture of marine engines and accessories, and additional machine tools have been placed to take care of this product. The demand for general supplies continues fairly heavy and prices in many instances are still inclined upward.

Scrap

Railroad embargoes and freight congestion are affecting the shipment of materials, and it is often difficult to obtain delivery. The continued shortage of coke has created an increased demand for turnings and borings, with the result that this class of scrap has become quite active. Low phosphorus scrap is in heavy demand. A firm outlook is expected until relief is shown in railroad transportation. The local situation is active, and dealers have advanced prices. Old coppers are 2c higher, quotations ranging from 22c for light to 26c for heavy. Composition turnings are one cent higher at 18c. Brass clippings with a similar advance are quoted at 17½c. Machine cast iron has advanced to 21c, while an advance of 2c on steel turnings raises the price to 9c. Shafting is now 21c, stove plate 14c, scrap zinc 8½c, and aluminum 36c; these prices all indicating an advance of one cent per lb.

Toronto, Ont., Feb. 1.—The outstanding feature is the railroad situation. It is undoubtedly more serious, as the shortage of transportation facilities is hampering manufacturing operations to a greater extent on account of the difficulty in obtaining raw materials and coal. Cars continue to be held up and shipments delayed, notwithstanding the efforts that are being made to secure relief. The railways are handicapped by a shortage of cars and labor, while the severe weather has made operating conditions more difficult to control. Passenger schedules have been reduced to provide additional motive power, and a strong effort is being made to cope with the situation.

Steel

An acute situation has developed in the iron and steel trade on account of the transportation difficulties and consequent scarcity of coke. Supplies of coke are so difficult to obtain that furnaces cannot be operated at capacity, and the output of steel is, therefore, restricted. Practically the entire output of the mills is required for munitions, and wire and wire products for export, thus leaving a very small tonnage to meet the domestic demand. In this respect the situation is getting worse owing to the reduced production, causing considerable inconvenience to domestic consumers. This, however, is unavoidable, as war requirements have first call on the mills. All the steel companies have heavy commitments for this year, and have also considerable tonnage on their books for 1918. The situation is, therefore, very strong, and there is no indication at present of any weakness. Although steel prices are at a high point, there is every possibility of further advances, particularly in some lines, if they are to reach levels in keeping with the cost of raw materials. Prospects of an early peace having been dissipated, the steel market has assumed renewed strength, which will no doubt be maintained until final peace negotiations are renewed. When this desirable condition materializes, negotiations will doubtless cover an extended period during which time the market will become to some extent adjusted in accordance with the new conditions, and prices will probably be more or less stationary for a time before any pronounced weakness develops in the way of lower values. In the meantime, export demand continues good, but the steel companies are experiencing much difficulty in filling orders owing to the scarcity of raw materials. Deliveries are more backward than ever, for the reasons stated above, particularly on plates and wire rods, for which there is a heavy demand.

Unlooked-for developments in the steel market in the United States tend to a belief that capacity production is unlikely, at least for several months. Railway embargoes have resulted in a curtailment of steel production, and the mills are falling behind on deliveries. Shortage of cars has resulted in supplies of coke being cut off, seriously affecting the mills by lowering production and restricting the shipment of finished steel. Prices of raw materials, such as ferromanganese, speigeleisen and ferro-silicon, are advancing, while coke and labor costs are also higher.

Pig Iron

The pig iron situation is getting more acute owing to the shortage of coke, which is affecting furnaces both in Canada and the United States. The Steel Company of Canada have let one furnace down, while the other is only operating at about two-thirds capacity. As the furnace which is not in operation was producing foundry iron, there is practically no domestic pig iron of this grade to be obtained. The furnace which is in operation is producing basic pig iron for steel-making. Grey iron foundries are also suffering from the shortage of coke, and some plants have been obliged to shut down. It is reported that over twenty furnaces in the Pittsburgh district have shut down owing to the coke situation. Canadian consumers are buying considerable tonnages of pig iron from United States' furnaces. No quotations are obtainable on Canadian pig iron, and United States grades are unchanged.

Scrap

The market for scrap is firm and steady, with prices unchanged. The embargo on the export of steel turnings has been lifted again, but is still in force on other steel scraps. Stocks of steel turnings have accumulated, and there is a greater supply than can be used. There is a continued heavy demand for heavy steel scrap, and prices are holding very firm. Ingot metals are firmer, with a fair demand.

Machine Tools

The machine tool situation is unchanged. Business continues quiet, although there is some demand for single tools. Consumers generally are awaiting developments pending a decision regarding further shell contracts.

Metals

The elimination of peace talk has had a favorable effect on the metal market, and the situation generally has improved. There is a firmer undertone throughout, and advances have been registered in tin, lead, antimony and solders. Business locally continues very good, and the trade is in a prosperous condition.

Copper.—There has been very little copper offered for sale lately, and second-hand metal is off the market. The position of copper continues to be a very strong one, and higher prices appear to be likely. Quotations are still nominal, and are unchanged at 36c per pound.

Tin.—The advance in London has been reflected in higher prices here, although New York is unchanged. Tin is now quoted locally at 47½c per pound.

Spelter.—There is an improved sentiment in the market, and a better demand for spelter. The outlook, however, is unsettled, as spelter would be adversely affected by further peace proposals. Local price unchanged at 13½c per pound.

Lead.—The market is strong and quotations nominal. The "Trust" is holding the price at 7.50c New York, but the "Independents" are quoting 8c to 8¼c New York. Quotations locally have advanced ½c, and lead is now 10c per pound.

Antimony.—Quotations are higher, but nominal with a strong market, due to improved demand. Antimony is now quoted at 20c per pound.

Aluminum.—The market is dull and easy, with quotations unchanged at 68c per pound.

Solders.—The advance in tin and lead has been followed by higher prices on solders. The new quotations are ¼c per pound higher.

CANADA'S PROSPEROUS YEAR

PROBABLY one of the most interesting studies of the improvement in the economic position of the Dominion is to be found in a contrast of the business reviews issued by the Canadian Bank of Commerce for the past three years. From the depression and uncertainty that existed after the outbreak of the war to the development and decision that characterize trade operations at the present time would, were it not for the war, be an evolution covering at least a decade. Marvellous, therefore, as has been the transformation, it is by no means to be taken as a sign of complete commercial independence, for when the war is concluded the adjustment to peace conditions unless carried on with care and foresight, may to a greater or less extent interfere with the continuity of commercial progress and expansion for which 1916 was a banner year.

High Grain Prices

Canada's crops last year, despite the forebodings early in the season about a partial failure, were a success from a financial point of view. On the completion of harvesting in 1915 it became evident that we had been favored with a "bumper" crop, and the Northwest Grain Dealers' Association in November estimated the wheat crop at 307,230,000 bushels, our own estimate at that time being 320,275,000 bushels.

In previous years the Grain Dealers' September estimate has seldom been wide of the mark, but the farmers' deliveries to 31st August last revealed the fact that the 1915 wheat crop had exceeded even their November estimate by 70,000,000 bushels—that the crop had not merely been a "bumper" one, but represented a yield never before obtained in the grain-growing areas of any portion of western North America. The average yield of wheat for the three provinces was 30.2 bushels per acre.

Goods Fortune for Farmers

In 1916 the crops again gave exceptional promise until the end of July, when for the second time in twelve years black rust swept over the wheat fields of the Northwestern States and crossed into Manitoba, gradually spreading into the Southern half of Saskatchewan. Over the greater portion of Manitoba the damage was so severe that many fields yielded nothing, others only 6 to 7 bushels of feed wheat, and the average yield for the province was only 11 bushels of a low grade. Fortunately, Alberta escaped entirely and most of Northern Saskatchewan was affected only slightly, while in Southern Saskatchewan severe damage was confined chiefly to the eastern half.

Consequently with the extraordinarily high prices prevailing, it has been a year of great food fortune for farmers in Alberta and in part of Saskatchewan, and a year of disappointment for farmers in the remainder of Saskatchewan and in Manitoba. Even as to the latter, however, it is to be remembered that it was not a season of general crop failure. Oats and barley gave a fair yield, so that mixed farmers in the rust affected areas have not suffered any marked setback.

Live Stock Industry

The live stock industry shows a continuing development, and reports from most districts indicate a more pronounced disposition on the part of the smaller farmers to acquire stock. The progress made last year and in the past five-year period is indicated by the following figures of farmers' holdings of stock issued by the Provincial Governments:

	1910.	1914.	1915.
Horses	1,439,496	1,574,367	1,617,437
Cattle	1,822,020	2,460,419	2,687,437
Hog ..	676,615	1,553,565	1,015,679
Sheep	352,379	754,040	793,601

Cattle and sheep appear to be more in favor at present than hogs, and this finds confirmation in the following statistics of the receipts at the winnipeg stock-yards for the first ten months of 1915 and 1916, respectively:

	1915.	1916.
Cattle	110,057	120,064
Hogs	422,426	266,218
Sheep	9,952	15,656

Coal in Alberta

The coal mining industry of Alberta, notwithstanding the shortage of labor, shows a very large increase in the quantity of coal mined, due partly to the increased demand and partly to the fact that a steadier production was rendered possible by dealers ordering supplies in good time instead of waiting until the approach of winter, the season of car shortage. The figures in tons for the past three years are:

1914	3,821,739
1915	3,434,891
1916	4,300,000 (Est)

The immigration of settlers from the United States to the western provinces shows a revival. The figures for the ten months ending 31st October are:

	No.	Cash	Effects
1915	3,559	$2,022,918	$285,950
1916	4,788	2,825,756	854,152

Pacific Coast

Throughout British Columbia a much improved tone prevails in comparison with that recorded in our last report; business is larger in volume and improved in quality, while payments have been made with greater promptness than heretofore. There is a general scarcity of labor, though some improvement has taken place since the crops on the prairies were harvested and the laborers returned. The population of the province, however, has unquestionably been reduced, though mainly through the recruiting of over 30,000 men for overseas service. The cost of living, in this province as elsewhere, has increased, but a spirit of economy is more general and the people are becoming more reconciled to having to study what to do without rather than what to spend.

TRADE ENQUIRIES

FURTHER particulars regarding the following enquiries may be obtained from the Department of Trade and Commerce, Ottawa.

400—Chemicals.—A reliable English firm of commission agents located in Buenos Ayres would like to hear from Canadian manufacturers of sulphate of alumina and other heavy chemicals used in the manufacture of soap, matches, paper, etc.

401—Iron and steel bars, wood-pulp, fencing wire.—An English firm of manufacturers' representatives would like to receive quotations c.i.f. Buenos Ayres, for iron and steel bars, wood-pulp, fencing wire, if shipment of same can be made immediately.

402—Asbestos.—A Japanese firm in Tokyo wishes to get into touch with suppliers of asbestos in Canada.

403—Sulphuric Acid.—A London firm who deal in sulphuric acid would be glad to receive offers from Canadian manufacturers.

427—Iron and Steel.—A Johannesburg commission house, familiar with the iron and steel trade, seeks the representation of Canadian manufacturers of bar iron, angle iron, iron tubing and wire nails. Immediate correspondence requested.

412—Oxides of Cobalt.—A London manufacturing company asks to be placed in direct touch with Canadian producers of oxides of cobalt, both black and prepared, and also of cobalt metal.

CUBAN DEMAND FOR GASOLINE MOTORS

UNITED STATES CONSUL R. M. BARTLEMAN, Cienfuegos, Cuba, in a report to his Government published in the Commerce Reports, says that a very fair demand for gasoline motors exists in the Cienfuegos district, but on account of the excessive advance in the price of gasoline there is a tendency to turn to the crude-oil engine.

The following quotations have been ob-

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Cousul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa. British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—H. R. Poussette, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H Ross, Stock Exchange Building, Melbourne. Cable address. Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—Acting Trade Commissioner, Lonja del Commercio, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—G. B. Johnson, P. O. Box 109, Yokohoma. Cable address, Canadian.

HOLLAND—Acting Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address. Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrivskaya, Ploshch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 27-28 Pearl Building, East Paradise, Leeds. Cable address, Canadian. F. A. C. Bickerike, Canada Chambers, 36 Spring Gardens, Manchester. Cable address. Cantracom. J. T. Lithgow, 87 Union Street. Glasgow, Scotland. Cable address, Contracom.

SPECIAL TRADE COMMISSIONER—LUMBER

H. R. McMillan, visiting Europe, Africa, Australasia and the Orient.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin, Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum Grubbeged No. 4. Christiania, Norway. Cable address, Sontums.

CANADIAN HIGH COMMISSIONER'S OFFICE

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

tained: $1\frac{3}{4}$ horse-power, \$78; $1\frac{1}{2}$ horse power, \$55; $4\frac{1}{4}$ horse-power, \$95; 4 horse-power, \$180; 6 horse-power, \$185, \$215 and \$375; 8 horse-power, \$285.

Dealers also offer a complete plant for lighting and industrial purposes (the heating feature being superfluous for this climate), consisting of engine, motor and storage battery, with a capacity for 10 lights, costing at factory \$150, placed on market here at \$240. Others, of 20-light capacity, with a factory cost of \$200, sell here at \$320.

In this district pretentious residences warranting the installation of electric lights or farms where the development of power is desirable are very limited in number. Every important centre of population, including the sugar plantations, has service for both power and light, although it is probable that much of the current is available only during the "lighting" hours, from sunset to sunrise. In this city, however, it is stated that everything is in readiness for daily service except the running of the cable, the delivery of which has been delayed several months.

WAR PURCHASING COMMISSION

FOUR large volumes are comprised in the report of the War Purchasing Commission tabled in the House of Commons, Ottawa on January 23, and covering the work of that body from the time of its appointment, up to December 31st, 1916. Details of all accepted tenders in thousands of contracts are given along with all the Orders in Council relating to war purchases.

The commision is composed of Hon. A. E. Kemp, George F. Galt and H. Laporte. In a letter transmitting the report, Mr. Kemp says the duties of the commission include the supervision of purchases for the Canadian forces as well as the naval service and internment operations of clothing, equipment, munitions and supplies of every sort and the supervision of contracts for transportation. Purchases are made upon a tender or competitive basis. Inspection is caried out at the headquarters in Ottawa.

The rates charged for the transport of bodies of troops of 350 or more of all ranks for distances over 100 miles are one cent per mile second-class whether the railway company provides second-class accommodation or not, and one and a half cent per mile first-class. The rates for numbers fewer than 350 and for distances of 100 miles or less are one and a third cents per mile for second-class and two cents for first-class. The rates for freight are on a commodity basis of fourth-class on military equipment. For the transport of troops they are fixed by an agreement in connection with the sailing of each vessel these rates on an average being \$61 for officers and for other ranks varying from \$33.75 to \$36.25, according to the class of vessel.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Toronto, Ont.—The Toronto Harbor Commiisson has started laying a track for the new industrial siding to the site of the proposed steel plant.

Toronto, Ont.—It is reported that an airplane factory, to cost $200,000, is to be erected on nine and a half acres on the west side of Dufferin Street, north of Lappin Avenue.

Longueuil, Que. — The Standard Foundry on St. Elizabeth street, Longueuil, was the scene of a fire on Jan. 23. Most of the damage to the building and plant was due to water, and was estimated at about $1,000.

Toronto, Ont.—The Toronto Harbor Commission is preparing the sixty-acre site recently purchased for the erection of the new steel plant for the Imperial Munition Board. A track has been laid and the pile drivers are ready to start operations.

Montreal, Que.—So far as known at the head office of the Canadian Car & Foundry Co., in Montreal the company has no intention of rebuilding on the site of the factory at Kingsland, N.J., destroyed by explosion and fire on January 11.

Preston, Ont.—The Town Council will consider submitting a by-law to the ratepayers authorizing a loan of $75,000. Preston Car & Coach Co., or the endorsement by the corporation of a like amount of the company's bonds. The company sustained a loss of $80,000 or $90,000 over the above the insurance on acount of the recent fire.

Owen Sound, Ont.—Following its incorporation, the new Nut, Bolt & Wire Co., is planning extensive alterations to the plant of the Nut & Bolt Co., which they absorbed. A new boilerhouse will be erected, a baking oven for annealing wire will be installed, and a wire cleaning house will be built. The new machinery is to be made in Owen Sound.

Trenton, Ont.—The British Chemical Co. have purchased an additional 36 acres of land, besides the 142 acres upon which they are erecting their plant here. It is said also that they have an option on two additional pieces of land of 44 acres and 80 acres. It is further stated that four hundred houses are to be erected the coming summer to accommodate the employees.

Minden, Ont. — Six miles north of Minden Village, on a property owned by Hugh Coulter, there is said to have been discovered a mining proposition that may prove of much value. Feldspar, magnetic iron and other minerals are said to have been found in large quantities. Also that a small piece of the rock was smelted and turned out a fine sample of steel.

Three Rivers, Que.—The St. Maurice Paper Co.'s new paper mill, at Three Rivers with a capacity of 100 tons of newsprint a day, is now virtually complete, and should start operations in the next week or ten days. Concurrently with its construction, a 60-ton sulphite mill, and a 50-ton sulphate mill have also being going up. The entire new construction programme, supplementing the 100-ton mechanical wood pulp now operating, should be completed by about March.

ELECTRICAL

Brantford, Ont.—The wiring and equipment of the Western Counties Electric Co. in Brantford township have been purchased by the township for $4,000 and the Hydro-Electric Commission will now be asked to at once proceed with the extension of the system to Grandview, Parkdale and Echo Place, supplying also Hydro-electric light and power to township residents.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

MUNICIPAL

Brantford, Ont.—The City Council are in the market for special castings required during 1917.

Fernie, B.C.—There is a coal shortage here, and unless supplies are received in a few days, the city power plant will be closed.

Calgary, Alta.—The Northwestern Engineering & Supply Co., has been granted a franchise to operate an electric light and power plant in Drumheller.

Montreal, Que.—The Board of Control will open tenders on February 9 for motor sweepers and street sprinklers, for which the sum of $16,000 has been set aside in the 1917 budget. It was resolved that prices on the new machinery might be quoted by manufacturers as well as by agents.

Lindsay, Ont.—Tenders will be called in about two weeks for five pressure type mechanical filters for water purification. The total capacity of the filters will be 1,800,000 Imperial gallons per day. Bids will also be received at the same time for the erection of a filter house and an extension to the present pump house.

Sherbrooke, Que.—At the next meeting of the City Council a by-law, will be submitted to authorize the borrowing of $500,000 for the purchase of the Two Miles Falls Power at Weedon, to develop the same and construct a transmission line to Sherbrooke. A report was made by Messrs. Francis & Co., Montreal, recently on the power. It was estimated that to fully develop the power and install equipment it would cost $1,452,900.

GENERAL

Niagara Falls, Ont.—Damage to the extent of $200,000 was done by fire on Jan. 27 to the American Cyanamid Co. factory.

Ford, Ont.—A new concern the Canadian Lamp & Stamping Co., contemplate building a factory here to cost $27,000.

Fredericton, N.B.—A company is being organized here to manufacture cement products. W. C. E. Richard is interested in the enterprise.

Montreal, Que.—The shoe factory of Eugene Guay & Co., located in the rear of 230 St. Margaret street, was completely gutted by fire last Friday. Damage is estimated at about $10,000, covered by insurance.

Tyndall, Man.—Fire on Jan. 23 destroyed the cut-stone plant owned by the Wallace Sandstone Quarries, located at Lyall near here. The loss is estimated at $250,000.

Montreal, Que.—The factory of Jennings & Co., Wagon builders, 15 Wellington street, was the scene of a bad fire last Friday night. The Jennings Co., was engaged in the manufacture of trucks and limbers, which were destroyed, and the whole building was completely gutted, with a loss of about $25,000, well covered with insurance.

Toronto, Ont.—The factory of the Channel Chemical Co., manufacturers of the "O'Cedar" mops and polishes at 369 Sorauren Avenue, was badly damaged by fire last Thursday. The total loss is estimated at $25,000, of which about $20,000 is to the stock and the remaining $5,000 to the building. The latter is owned by Robert Watson, and in both cases the loss is fully covered by insurance.

CONTRACTS

Winnipeg, Man.—The Greater Winnipeg District Board has decided to award the contract for the construction of ten miles of pipe line, at a cost of $1,300,000, to the Winnipeg Aqueduct Construction Co. The matter, however, has not been finally settled, as other contractors have raised objections over the award.

Fredericton, N.B.—F. L. Boone, of St. Marys, has been awarded the contract for the construction of the D'Aigle Bridge, Madawaska County. The D'Aigle Bridge will be a 34-feet reinforced concrete span with stone embankment, and will be situated over Nine Mile Brook, near St. Leonards. The contract price is $4,395.60.

BUILDINGS

Toronto, Ont.—Application has been made for permission to erect a $200,000 aeroplane factory west of Dufferin street and north of Lappin avenue.

Toronto, Ont.—Application has been made at the City Architect's Department for permission to erect one section of the big $15,000,000 departmental store. The section will be located at the corner of Yonge and College and will be 250 feet by 250 feet and fifteen stories high with basement and subbasement. The height of the building from the cellar to the roof will be 316 feet and 280 feet above the kerb. The cubical capacity will be 19,750,000 feet and the construction will be of skeleton steel with terra cotta floors. Very little concrete will be used except for the foundations. The outside material will be of brick and stone. The cost is estimated at $3,160,000. H. J. White Ryrie Building, Toronto is the architect.

TENDERS

Winnipeg, Man.—Tenders will be called until February 12, for works required for the completion of the new Parliament Buildings, which include the following:—Heating and ventilating, electric conduit and wiring. Thos. H. Johnson, Minister of Public Works, Winnipeg.

Winnipeg, Man.—Tenders will be received by R. D. Waugh, chairman of Commissioners, Greater Winnipeg Water District, up to February 5, for the supply of indicating and recording apparatus for two Venturi meters. Specifications may be obtained at the office of the district, 501 Tribune Building.

Ottawa, Ont.—Tenders for tungsten lamps, for the Departmental Buildings, Ottawa, Ont., will be received until Friday, February 2, 1917. Specification to be seen on application to the Clerk of Works, Postal Station "F," Toronto; to the Overseer, Dominion Buildings, Central Post Office, Montreal, and to the Chief Architect, Department of Public Works, Ottawa.

Montreal, Que.—Tenders, addressed to the Board of Commissioners, City Hall, will be received until February 9, for the supply and delivery of auto sprinkler-flushers and auto sweepers. Copies and specifications and forms of tenders may be obtained by the interested parties at the office of the superintendent of purchases and sales, where all necessary information will be given.

Ottawa, Ont.—Tenders will be received at this office until February 12, for the supply of: Brooms and brushes, chain, coal, hardware, hose, oils and greases, packing, paint and paint oils, Manila rope, wire rope and steam pipe, valves and fittings, for the requirements of the departmental dredging plant in Ontario and Quebec during the fiscal year 1917-18. These forms of tender can be obtained at the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Winnipeg, Man.—Tenders will be received at the office of the Winnipeg Public School Board up to February 8, for supplying the following material:—Blacksmith's coal, drawing, hardware, iron, steel, lumber, oils, varnishes, electrical, printing, required in connection with the Technical and Manual Training Schools of the city. For specifications, forms of tender, and further information required, apply direct to the Commissioner of Supplies, School Board Offices. R. H. Smith, secretary-treasurer, W. P. S. B.

Toronto, Ont.—Tenders will be received up to Feb. 12, 1917, for the supply of the following materials for the Township of York, 24 in., 12., and smaller sizes, cast iron pipe; 24 in., 12 in., and smaller sizes of special castings; 6 in., 12 in., and 24 in. valves; air valves, hydrants, tops, covers and plugs, venturi meters and recorders; 6 in., 12 in., and 24 in. check valves. Plans and specifications may be obtained from Frank Barber, township engineer, 57 Adelaide Street West, Toronto.

RAILWAYS—BRIDGES

Winnipeg, Man.—The Greater Winnipeg Water District plant to operate an electric road between St. Boniface and Transcona.

Vancouver, B.C.—Work has started on the pile driving contract as a preliminary to the construction of the new C.N.R. station which will be built of reinforced concrete. There will be about 400 tons of reinforced steel used and about 10,000 cubic yards of concrete.

Niagara Falls, Ont.—The cantilever bridge owned by the M.C.R. is to be rebuilt, and work has already started. W. T. Tuttle, an engineer from New York, has arrived to take charge of the work. It will take eight months to build the new bridge, it is estimated, and meantime the present bridge will be used. It was opened in 1883.

Winnipeg, Man.—Application will be made at the present session of the Provincial Legislature on behalf of the Central Canada Railroad & Power Co. for an extension of the time for commencing and completing the construction of the railway authorized in 1905. The powers granted previously authorize the promoters to construct a railway from Winnipeg or St. Boniface to the northern limits of the province. The re-enactment of the act without amendment, as is planned, would extend the authority to the shores of Hudson bay, and would give J. D. McArthur and his associates the right to compete with the Dominion Government's Hudson Bay railway.

INCORPORATIONS

Capital Machinists & Founders, Ltd., of Ottawa have been incorporated with a capital of $50,000.

The Canadian S. K. F. Co., has been incorporated at Ottawa with a capital of $50,000 to manufacture and sell ball bearings and machinery at Toronto. The incorporators are Allan H. MacCaffray of Hartford Conn., also Percy O. G. Jones and James D. Becking of Toronto.

The Mack Brick Co., has been incorporated at Ottawa with a capital of $500,000 to manufacture brick and terra-cotta etc. The head office is at Montreal and the incorporators are Richard T. Heneker, Henry N. Chauvin and Harold E. Walker all of Montreal.

The Century Coal & Coke Co., has been incorporated at Ottawa with a capital of $500,000 to carry on a coal business and to manufacture coke with head office at Montreal. The incorporators are Charles Murphy, Harold Fisher and Stanley G. Metcalfe all of Montreal.

The Huntley Mfg. Co., has been incorporated at Toronto with a capital of $50,000 to carry on business as millwrights and to make mill and cannery machinery at Tillsonburg, Ont. The provisional directors are Charles G. Hammond and Leroy C. Hammond of Silver Creek, N.Y., also William H. Bennett of Tillsonburg, Ont.

PERSONAL

Duncan B. Ellis, a veteran Windsor lake captain, was knocked off the car ferry and drowned on Jan. 22.

Lord Cowdray, head of Messrs. Pearson, contractors, and of the Mexican Oil Co., has been elevated to the rank of Viscount.

Captain John E. Tobin, a veteran of the Civil War, and for many years master of vessels, died at Windsor, Ont., on Jan. 22.

R. E. Speakman, city engineer of Brandon, Man., for the past nine years, passed away at Rochester, Minn., hospital on January 13, aged 70.

Sir George Foster is back in Ottawa from London where he attended the meeting of the Dominions Royal Commission drawing up the final report.

A. P. Hoag, for the past two months superintendent of the shell department of the Canadian Allis-Chalmers Co., Stratford, Ont., has been appointed superintendent of the Brantford Motors, Ltd., Brantford, Ont.

Toronto ... 101.

Manufacturing Gauges at a British Technical Institute*

By A. G. Cooke, M.A., W. J. Gow, A.R.C.S., and W. G. Tunnicliffe**

Not because of any recognized merit or skill, but through their connection with the largest Technical Institute maintained by the largest Education Authority, the authors of this article have been honored with an important share in practical constructive work in the standardization of an engineering industry. The work dealt with includes workshop details and methods of securing a high degree of mechanical accuracy under conditions of great urgency

AT the close of the session for evening classes in 1915, the personnel of the Mechanical Engineering Department of the L.C.C. Paddington Technical Institute was reduced to the Head, who, with the Principal, was continuing the engineering teaching of a Junior Technical School of 100 boys (14—16). Of the five permanent teachers of engineering, four had joined the Army and the fifth was "on loan" to a munition factory. From the elementary schools of the Council were transferred two metal-work instructors who had experience in gauge-making, Mr. W. G. Tunnicliffe and Mr. H. C. Christie. Under their immediate direction were placed five other metal-work instructors and sixteen woodwork instructors.

Boys of the Junior Technical School in their second year were also employed; the ultimate arrangement adopted being for classes of about seventeen to work every third week for forty-four hours. Experience confirms that this is excellent in results, and worthy of consideration as a permanent system of engineering training.

Machinery that had been in ceaseless use by day and evening students for ten to a dozen years could hardly be expected to be ready for work of the highest accuracy. But no other was available. Practically for all but the "roughing-out" machines complete reconstruction of those essential lathe parts on which precision depends was the first operation.

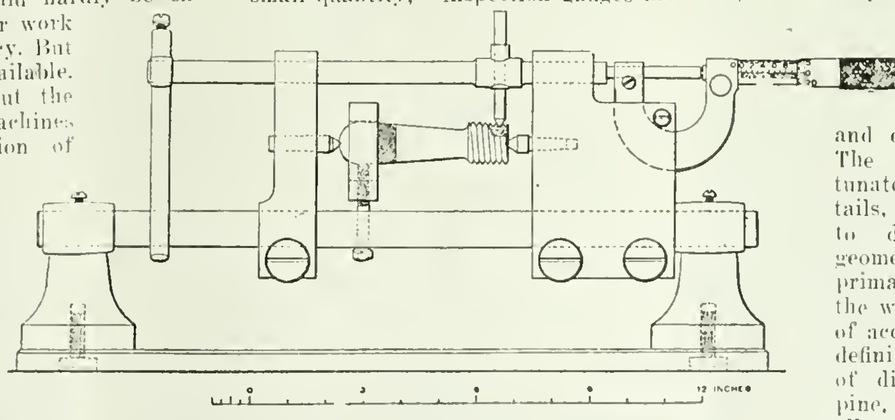

FIG. 1. APPARATUS FOR PITCH MEASUREMENT.

Nature of Manufacture

An explanation is necessary as to the nature of the work undertaken, and its place in relation to the whole industry. The precision desired for primary standards for laboratory testing is limited by practical possibilities only, and the manufacture is not a "commercial proposition." Inspection gauges, or secondary standards, are to be manufactured within a determined though small range of variation or "tolerance." This tolerance should be regarded as a definition, not an error limit. Within the tolerance all values are "correct." In consequence, the manufacture is entirely a question of competitive cost and urgency of delivery.

That standardization is the key to efficient manufacture and a large output is universally recognized. It is not so well understood that simply on account of the magnitude of the output, apart from the question of excellency of workmanship required, the necessity for standards of a higher order of accuracy arises. It is easy in a small workshop to insure by trial that all fitting is satisfactory; in fact, the initial magnitudes are generally determined by the same tools and standards. In a larger workshop the work is linked by more accurate gauges; and it generally matters little if the absolute measurements vary appreciably from that specified in the design. But when an industry grows to a national or international extent, the standards must aim at specified dimensions of absolute magnitude, defining exactly the limits of permissible variation on either side of the standard, so as to include all acceptable, and reject all unacceptable variations from the correct value. In the language of the calculus, in order to limit variations to a defined "small quantity," inspection gauges are required to be true to the "second order of small quantities." It is just in so far as we can rely on the accuracy of inspection gauges to define the limits of variation permissible, that the designer can allow those limits to be extended with safety. Hence the apparent paradox that high accuracy in the inspection gauges allows more laxity, and so increases facility and speed of manufacture.

Limit-Gauges

There is no need to describe in detail the principles of limit-gauges for measurements of length and diameters. Both workshop and inspection gauges were manufactured, the essential difference being that the former must be adjusted to be within the specified limits, while any tolerance permissible in the latter must be outside, so as to pass all acceptable work. Tolerance in a workshop gauge tends only to increase the margin of safety, enforcing greater care in manufacture than necessity demands. Uncertainty and variation in inspection gauges is not only unjust to one manufacturer, but affects all by necessitating closer limits.

The necessary order of accuracy for this type of gauge, three ten-thousandths is generally specified, can be obtained with universal grinders. As the demand was urgent, and grinding machinery not available, they had to resort to handwork. Lapping with high-speed motors up to three or four thousand revolutions, and other devices for acceleration, were developed.

Position-Gauges

The greater part of the work entrusted to this Institute consisted of a class of gauges determining position or some geometrical feature, involving greater difficulties in theory and practice than a single directly measured dimension. Concentricity, perpendicularity, or parallelism, and distance between centres of turning and drilling, are examples. The authors are unfortunately unable to give details, but it will be seen that to determine some such geometrical conditions, or primary measurements, in the work to be tested, limits of accuracy are allowed by a definite variation in the size of diameters of cylinders, pins, or drilling, so as to allow slackness. The gauge limits the combined errors in jig or automatic tool work.

It will be seen that any variation of the inspection gauge, as regards the primary condition, simply displaces the limits which it is intended to give, rejecting satisfactory and accepting unsatisfactory work through a range of double its own error. The practice is to allow a gauge tolerance of only 0.0001 in the primary measurement, and a combined tolerance of 0.0003.

Screw Gauges

The methods by which they attained the high accuracy required for screw-gauges are selected for special description. They try to limit any discussion

*Read before the Institution of Mechanical Engineers, London, Jan., 1917.

**London County Council, Paddington Technical Institute.

of scientific principles to such as directly affect their work in the construction of the gauges. In screw-gauges the gauging surface is an elaborate skew surface, all parts of which are required to be within the limits, in general fixed at three ten-thousandths measured radially from the axis [0.0006 in diameter]. This means only about $1\frac{1}{2}$ ten-thousandths normally to the slope of the threads. It must not be forgotten that this is the second order of small quantities necessary to define a larger variation permissible in the work. As a variation of which this is 5 per cent. would allow a sheet of the *Times* newspaper to be used as packing (three thousandths), it cannot be regarded as too fine.

for this not only the amplitude but the length of the periods must be considered, and probably also the method of lapping. Short periods and lapping with high speeds through several turns of the lap seemed necessary to success.

Workshop Measurements

It was found absolutely necessary to design and make for themselves instruments by which measurements of pitch and the diameters of the screw-gauges could be made on the premises, and optical apparatus by which screw-cutting tools could be shaped and the sections of the screw-threads examined. Details of these may perhaps be of interest, not as examples of high accuracy of physical measurement, but of practical methods suitable to the workshop.

and final pitch diagrams of test-pieces from the same lathe before and after correction. The test of Fig. 3 was taken on opposite sides of a test-piece of fourteen threads to the inch, the leading screw-pitch being presumed four threads to the inch. Analysed, it shows a fairly uniform progressive error of 0.0022 per inch, with superimposed periodic errors corresponding to the revolution of the leading screw, of amplitude 0.0004 inch. The lathe was in good condition, fairly typical of ordinary workshop accuracy.

Two methods of correction for progressive error were considered:—

(a) By accelerating the motion of the top slide of the compound rest by means of a weighted lever attached to the screw. The screw of the slide was turned at a uniform rate as the saddle traversed along the bed of the lathe, by making the end of the lever down an inclined plane, the slope of which could be readily determined from the known pitch error.

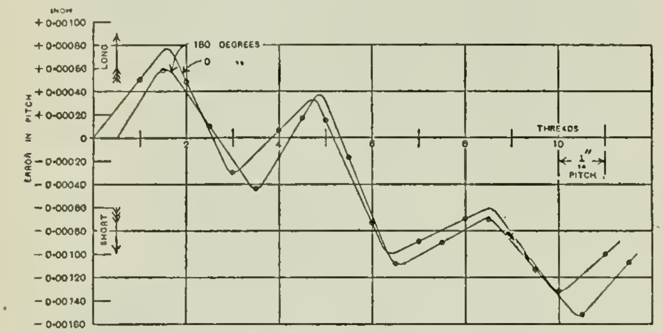

FIG. 2. TESTS TAKEN ON OPPOSITE SIDES OF A TEST PIECE OF 14 THREADS PER INCH; LEADING SCREW PITCH, 4 THREADS PER INCH.

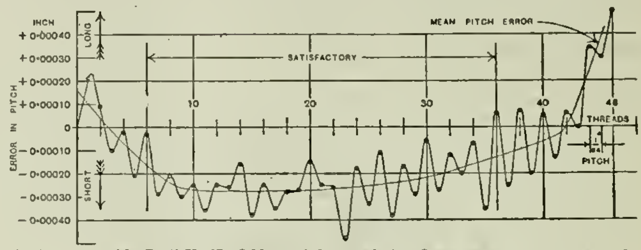

FIG. 3. FINAL TEST ON A SCREW SHOWING A SATISFACTORY RANGE FOR A LENGTH OF $1\frac{1}{4}$ INCHES.

It should be evident that the accuracy in pitch of the lathe used should be such that no divergency from the correct value greater than about $1\frac{1}{2}$ ten-thousandths should exist throughout the range used. For this would cause a skew surface otherwise cut in correct shape to the mean value to pass outside the limits allowed. If any further error in pitch exists, up to an extreme value of three ten-thousandths, it is only possible to keep within limits by thinning of threads, reducing the effective diameter, and the practical difficulties of the reduced margin increase rapidly if the above error is exceeded. The authors found that the lathes by a number of manufacturers showed an error in pitch of about two in a thousand, always short of specification. This uniform or progressive error is fairly easily corrected by change of gear-wheels, as will be shown by an example, but indicates the lamentable need for standardization in leading screws. Superimposed on this error were periodic errors, initial and produced by wear, requiring measurement, analysis and correction. It is desirable to repeat that they are aiming not at perfection, but a precision defined by tolerance. In a choice between methods of correction, that which will permanently rectify a discovered cause of variation so as to bring it within the defined limits, is infinitely preferable to any method of compensation which, though more capable of refinement, would allow redevelopment of error in prolonged heavy use, thus delaying output.

The periodic error is amenable to reduction by a final lapping process, but

The apparatus for pitch measurement is shown in Fig. 1. By its use on test-pieces they were enabled to analyse step by step the errors of pitch in lathes. One example will be given in some detail. The pin, which is moved from groove to groove, followed by micrometer, is turned to a cone of angle slightly less than 55°, and the point removed to insure that the pin touches not the bottom, but the sides of the groove. Supreme care, by good fitting, is necessary to insure that the points of contact follow a line parallel to the axis of the screw.

The differences between the micrometer readings for each groove, and those calculated for a correct screw of the presumed pitch, are plotted as ordinates in Figs. 2 and 3. These are selected from a large store of records as the first

(b) By selecting a new train of wheels, a process demanding some considerable calculation by trial and error for different pitches, but which has proved quite possible in all cases. For example, the train of wheels, drivers thirty-eight and twenty, followers ninety-one and fifty, gives a pitch of twenty-four to the inch correct to less than 0.000007.

The periodic errors corresponding to the revolution of the leading screw may be due to:—

(1) Reproduction of an error in the leading screw.

(2) An axial movement of the leading screw with each rotation, owing to both

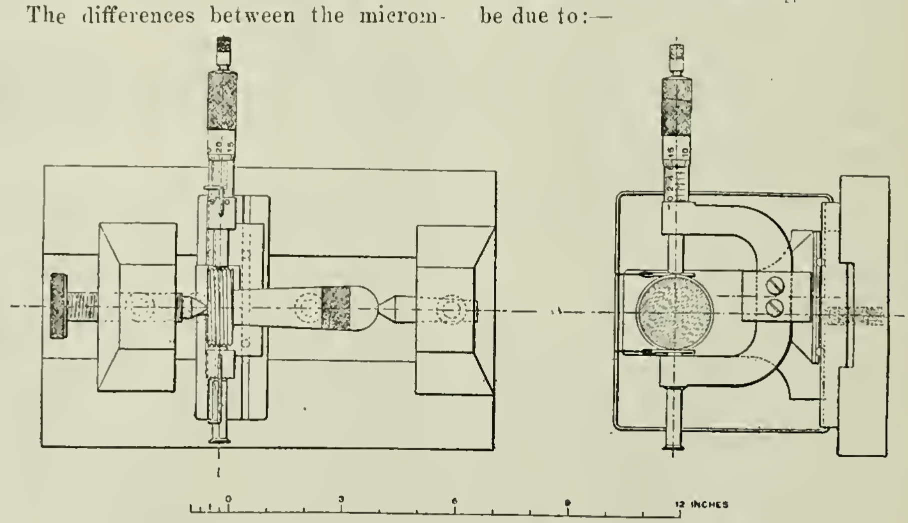

FIG. 4. APPARATUS FOR EFFECTIVE DIAMETER MEASUREMENT.

the thrust collar and bearing being out of truth.

(3) Lack of straightness or stiffness in the leading screw causing oscillations at the point of contact of the nut.

To correct (2), the collar bearing on the leading screw was dispensed with, and the thrust was carried by a single ball-bearing applied to an enlarged centre on the leading screw. The collar was turned off and the screw made to run free in its bearing. A half-inch ball was used, and the thrust taken by a bolt screwed through a bracket, and locked in position, the end of the bolt being made intensely hard.

After testing and correcting the change-wheels for eccentricity, it became evident that a more accurate and rigid leading screw was necessary. A new leading screw was cut on the milling machine on a sleeve of 2 inches diameter and 8 inches in length, with a pitch intended to be twelve threads to the inch. A split nut $2\frac{1}{4}$ inches in length was clamped by a weighted lever. Mounted on the original leading screw as shaft a progressive error of 0.0008 was found, with a periodic error amplitude nearly 0.0003. On substituting a short stiff shaft the latter was reduced to an amount not exceeding 0.0002, which may be considered satisfactory. The progressive error was approximately corrected by the following gear-wheels:—

For 24 threads to the inch
45×30 Drivers.

38×71 Followers.
For 14 threads to the inch
36×67 Drivers.

74×38 Followers.

The final test showing a satisfactory range for a length of $1\frac{1}{4}$ inches is shown in Fig. 3. This length, carefully marked, was sufficient for the gauges required.

The apparatus for effective diameter measurement is shown in Fig. 4. The micrometer carriage, mounted on balls, is constrained to move in a plane at right angles to the axis of the screw to be tested. This apparatus may also be used for measuring core diameter, by using triangular prisms in place of the small cylinders.

An ordinary 0 to 2 inches micrometer, fitted with a special adjustable attachment to enable direct measurements to be made of core diameter, is shown in Fig. 5.

Optical Projection

Enlargement by optical projection was first resorted to for adjustment of the shape of tools for screw-cutting, and verification of the shape of thread. Finding the possibilities for accuracy of measurement were greater than was thought possible, and well within tolerance allowed, the use was extended to a large variety of gauges, particularly to plate gauges of shape, slots and holes, curvature and cone angles, etc.

The key to the method is to secure, as nearly as possible, a truly parallel beam of intense light, freed from heat rays by passage through a saturated solution of alum. An optical bench of great rigidity, and sensitive and universal adjustments, carries the gauge or tool and projecting lenses. The screen is at a distance of about 16 feet.

The necessity of a parallel beam (except for tool edges) should be obvious in dealing with gauging surfaces, such as plates and screw-threads, and adjustment for tangential or grazing incidence must be as fine as possible. This limits the field for simultaneous survey to that of the area of the projecting lens. A combination of three optical elements was designed to give variable magnification up to 400. About 180 is, however, ample, and visible in undarkened room. Where it was desired, as in a few cases, to cover a larger gauge length than about half an inch, a triple achromatic lens of 2 inches diameter and 6 inches focus was combined with an astigmatic lens. The area surveyed on this extended up to over $1\frac{1}{2}$ inches, with fifty magnifications on a 6 feet screen. Quick interchange of gauges and tools from optical bench to vise or lapping motor with the minimum of readjustment is essential.

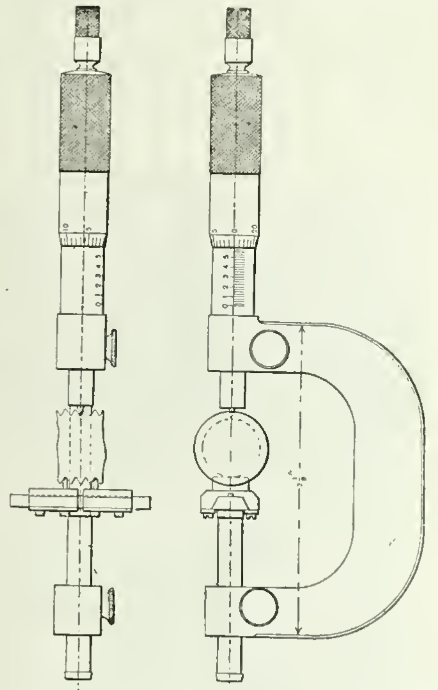

FIG. 5. APPARATUS FOR CORE DIAMETER MEASUREMENT.

Shaping of Screw-Threads

With a magnification of 166 a clear definition of the working edge of the single-pointed tool for screw-cutting is possible to much less than a ten-thousandth, this being represented by one-sixtieth on the screen. The angle and rounding off of the nose for the required pitch are adjusted with a fine oilstone to this degree of accuracy, after hardening without tempering, and quickly re-adjusted after wear. The same tool is used to cut the groove in a capping tool for the crests. It is then possible to insure correct shape, provided that the relation of core to effective diameter is checked by measurement.

In the final projection of the screw-thread in silhouette, a careful examination for symmetry is advisable, checking the setting of the tool. A small margin in all dimensions is left for lapping, which removes some residual errors, the margin being increased if a hardened gauge is required. For rapid lapping the screw-gauge is held in a self-centreing chuck on the shaft of a 1 horse-power electric motor. This is automatically controlled by a reversing switch, so that it rotates with precision, uniform torque, and any desired speed, two revolutions forward and backward.

The laps are made of cast iron, cut with a tap, or on lathe, split, and adjustable for wear. Frequent retapping retains the shape. For the core a lap is prepared with a slightly thin thread, and for effective diameter a full thread with crest removed.

HARDENING STEEL ON FALLING HEATS

MANY misleading ideas are current with regard to the correct method of hardening steel. For instance, one group of theorists advocate that the metal should be heated just through the critical range, and then cooled suddenly, whilst the temperature is still rising. This method, they state, confers the finest possible structure to the material. Moreover, unfortunately, many practical steel hardeners think that it is absolutely essential to quench the metal from the highest heat attained, and, accordingly, this method of procedure is the one largely followed in works practice. Herein lies the cause of a large percentage of hardening cracks. Let it be firmly impressed in the mind of the operator that quenching should always be done on a falling heat, otherwise the object is almost certain to crack in the bath. The falling heat permits the object to contract before it is put into the bath, and, in consequence, greatly reduces the risk of cracking and distortion. Once the material has been correctly heated to the hardening temperature the heat may be allowed to fall considerably before quenching, without in the least affecting the hardness of the quenched object. Experiments over a range of steels show that the temperature may be allowed to fall as much as 100° C. without showing a material reduction in the hardness.—Practical Engineer.

LOCAL SURFACE HARDENING OF GEAR TEETH

AN English process, reported to be largely used for hardening gear teeth, is known as the Vickers. It is local surface hardening and consists in applying momentarily to the surface of the part to be treated an intensely hot flame from an oxy-acetylene blow pipe. The surface, having been raised to a high temperature, is quenched by the cold body of the metal beneath. The equipment is that usually provided for oxy-acetylene welding, but the temperature of the flame is higher, the increase being obtained by adjusting the flame as for welding and then increasing slightly the supply of oxygen. The body of the work must be kept as cool as possible, to insure that the quenching is sufficiently rapid. For small parts it is customary to immerse them in cold water. Bodies of large parts may be left to cool off by themselves, but where necessary a supply of cold water may be allowed to flow over the work. In both cases the actual surface to be hardened is not to be submerged in water unless it is desired to give only a very shallow depth of hardened crust. In calculating the cost, for the purpose of comparison with furnace-treated work, it is pointed out that while for the latter process machining is carried out to approximate dimensions only, so that any distortion due to the heat treatment may be corrected by grinding and straightening, in the local surface-hardening process the work is machined to the finished dimensions, since no distortion is caused.

C.M.C. "FIRST AID" INSTALLATION

THE Canada Machinery Corporation, of Galt, Ont., have recently installed a "First Aid" Dressing Room at their plant, a further indication of the progressive policy being pursued and developed by the management.

The room, which is in every respect a modern hospital, is conveniently located in the centre of the works and is finished entirely in white enamel, having excellent artificial and natural lighting. The selection of the equipment was done under the advice of Dr. D. Buchanan, the shop Benefit Society physician, and in part consists of a steel white enamelled dressing table with glass shelves; a steel white enamelled dressing chair with adjustable arm and head rests and dressing basin; a large white enamelled dressing table with leather cushions and adjustable head and foot rests; a stretcher for use in the case of serious accidents; a large white enamelled cupboard containing various bandages, antiseptics, dressings, etc., and a special case of instruments for the use of the doctor in case he is called suddenly to the factory. Running hot and cold water are also available at a large wash basin.

In the treatment of accidents, all of the work does not fall upon the shop physician, for in each department are two qualified first aid men who have charge of accidents which may occur in their particular part of the works. This first aid dressing room is not a requirement of the Workmen's Compensation Act, the company taking the step in the interests of the employees and to make working conditions as nearly perfect as possible.

RECESSING TOOLS FOR SPECIAL WORK

Herbert's Monthly.

When a recess has to be cut at the bottom of a deep hole, the standard forms of recessing tool holder and cutter are unsuitable, for the cutter would stand out so far from the holder that it would chatter badly; similarly if the work stands a long way from the chuck chattering is also likely to occur, even if the recess is not far from the mouth of the hole. In cases such as these it is necessary to employ a method of recessing which ties up the recessing tool to the work; a good example of a tool of this type is shown in Fig. 1. The body of the tool holder is bored to receive a sleeve with an eccentric hole. In this eccentric hole there is a cutter spindle which can be rotated through about 90 degs. by means of the knurled handle; it will be seen that by doing this, the cutting tool is advanced from the centre by a distance limited by stops.

In Fig. 1, the work being recessed is an 18-pounder high explosive shell, and the revolving bush on the front of the sleeve fits in the bore previous to threading, and thus ties up the tool to the work. An adjustable collar is fitted on the revolving bush which butts up against the fuse seat of the shell and determines the distance of the recess from the front. On holes too small to use a revolving bush the sleeve may fit directly in the hole being recessed, and it is important to note that the sleeve should, therefore, be hardened.

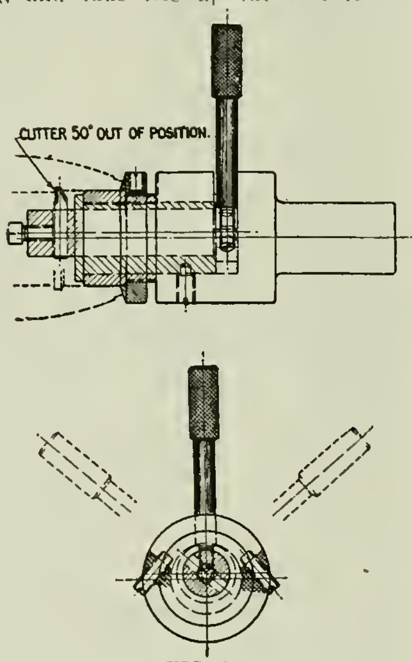

FIG. 1.

A good type of recessing tool for work in which the recess is near the front of the hole is shown in Fig. 2, and consists of a shank to which is fitted a sliding portion which can travel at 40 deg. to the axis of the spindle. This front sliding portion is bored to receive an ordinary circular recessing cutter, and at the front of the hole there is a hardened plate which can butt up against the work. The slide is kept in its normal position by a spring, and, when the turret is advanced towards the work, the front slide is arrested by the hardened plate which stops against the work, and, as the turret still advances, the recessing cutter travels across the axis of the lathe until the recess has been cut to the required depth, this being limited by the distance to which the turret is advanced. As this type of recessing slide requires a feed in one direction only, it is very suitable for use on automatics, on which it has been largely used.—Herbert's Monthly.

RECOVERY OF LUBRICATING OILS

LARGE quantities of oil are used in all machine installations, for lubricating purposes, and though the amount actually required to effect efficient lubricating is relatively small in each case, considerable excess is, for one reason or another, generally employed. For the sake of cleanliness, catch pans or grooves are provided to receive all oil working through bearings, so that the excess oil, mixed with dust and dirt, and usually "worn" to a more or less insignificant extent, is available for re-use, providing it be first cleansed. Machines for this purpose are to be had, but some of these require much attention in order to maintain satisfactory results, and cannot in any case be applied to thick cylinder oils and similar lubricants. The demand for a simple means of cleansing oils rapidly and economically is perhaps best met by centrifugal separators.

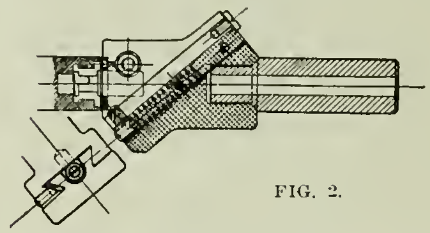

FIG. 2.

With more or less unimportant distinctions between individual makes, these machines comprise a conical whirling receptacle keyed on to a shaft and rotated at high speed within a stationary cast-iron drum. Oil to be cleansed is placed in a container within the whirling frame, and the latter is set in motion. Centrifugal force drives the oil up the smooth walls of the container to the rim, and hurls it thence through a fine brass gauze screen, which removes light foreign material carried up with the oil; heavy impurities remain at the bottom of the rotating vessel. In large installations it is preferable to employ separate machines to remove heavy particles from oil, and to clarify the latter completely. Purified oil may be conveniently compared with new oil by smearing a drop of each side by side on a sheet of clean paper. When the latter is held to the light, any suspended particles of muddiness in the separated oil will be easily detected.

C. G. Railways Appropriation.—The Canadian Government Railways call for an increased appropriation of $11,150,000 for working expenses. In the post office mail service there is a reduction of $200,000, but there is a long list of increases in the outside service of the Post Office Department. The vote for rural mail services is cut by $200,000.

Safe Practice at Blast Furnaces and Its Development--I.

By Frederick H. Willcox

In its efforts to increase safety in the metallurgical industries, the Bureau of Mines, Washington, D.C., has been studying the causes of accidents at blast furnace plants also methods for their prevention. This article describes the known dangers and makes suggestion of means whereby the risk of accident may be lessened or, better still, wholly avoided.

THE CAST-HOUSE CREW

LABORERS and new men should be made acquainted with the possibilities of slips, gas, breakouts, and bursting tuyeres.[1] If you can show them how to be less clumsy in handling tools do so, because awkward men may injure others as well as themselves. If you see anyone doing something that is dangerous or standing in some place where he might get hurt, tell him of the danger. If a man's clothes catch on fire, do not let him run. Put the fire out with a hose, or roll him in sand and smother the fire by throwing sand on it, or wrap him in a blanket or coat. If a man is gassed or receives an electric shock get him into fresh air, notify the foreman, and give him artificial respiration at once; loosen his clothing, take any tobacco out of his mouth, and keep him warm.

Operators' Clothing

Always wear clothes made of wool or hard jean cloth if possible, and especially avoid greasy clothes, as they will readily catch fire. Wear stout shoes, having thick soles, and without cracks or holes, that are not too low, and fit tightly about the leg (see Fig. 12). Congress shoes and leggings are advisable. Wear goggles or a mask to prevent injury when handling hot metal or cinder, breaking scrap with sledges, or turning hose on hot material. Never wear ordinary gloves or hand-made hand leathers in handling jagged pieces of scrap. Leathers or gloves with a safety spring in the back are the only safe ones, as the scrap will frequently catch the glove or leather and may cause a serious sprain or fall.

When breaking runner scrap, slag, lumber, test pieces, etc., with sledges or a "Mulligan," use judgment in blocking up the pieces before breaking them. The closer the material is to the floor, the less probability there is that it will fly in breaking. When barring scrap, plates, or other objects, be sure that the point of the bar is firmly engaged, or that the bar will not slip off the block, before you lift or put your weight on the bar. Keep your working place cleaned up. Bars, drills, and long-handled tools should be kept where they will not fall and injure anyone, by preference in a tool rack. If they are leaned against the wall, place them so they can not easily be knocked over or fall down. Don't leave tools where men can stumble over them. Remove burned drills and bars promptly. Watch out for hot bars and don't throw bars without looking to see whether some one may be hurt by their rebounding. Be careful when the cast house is full of steam; feel your way, do not attempt to go quickly.

When a blast furnace is being blown in or blown out, banked, stopped for a time, or started up, it is more dangerous than in regular running. At such times do not rely upon your own knowledge of furnaces, but follow every direction of the foreman strictly. Do not do any of the routine duties about the stoves, dust catcher, bleeder, cinder notch, tapping hole, or tuyeres except by direction of the foreman or blower. Don't go on the bustle pipe unless you notify the stove tender, keeper, or blower. When you have to work where you can smell gas, take frequent spells in fresh air and work with another man. Do not stay where there is gas unless your foreman knows conditions and that you are there.

FIG. 12. CAST HOUSE MAN WEARING LEGGINGS, GOGGLES, FELT HAT, AND WOOLLEN SHIRT.

Miscellaneous Precautions

Do not rest or stand under, near, or in front of blowpipes or tuyères, as they may burst or burn through, and throw metal, cinder, coke, or gas over you. When you know that the furnace is hanging, keep under cover and warn others. Keep away from the bottom of dust catchers, stove burners, downlegs, and manholes of underground flues at such times. In going to and from work avoid going under cranes carrying loads or under skip inclines, or through stock houses, boiler rooms, or places where you are unfamiliar with the work done there.

Do not try to do work other than your own about the furnace unless you are familiar with the work or have been ordered to do it. Especially do not try to help the hot-blast man on shutdowns or on work with the bleeder, mixer valve, or any regulating part of gas or blast mains unless everything you do is specifically directed by him. Many accidents have been caused by misunderstanding what some one else was doing.

Avoid Foolhardiness

Always use every safeguard provided —goggles, masks, shields, safety hand leathers, tongs, and gloves. (See January 25 issue, Figs. 6, 7, and 12.) They are provided to prevent injury to yourself, and men at other plants use them. Refusing to use them is not a sign of bravery or of familiarity with your work, but rather of foolhardiness and ignorance of the danger.

Do not drive the tapping bar through the skull in the tapping hole, or go on the last spell on the drill before you have placed the splasher and put a shield in front of the tapping hole, or a cover plate or sheets over the trough, in front of the splasher. (See Figs. 13 and 14), except under unusual circumstances. When it is necessary to pull the tapping bar out don't hold on to the "welshman." Lay a bar across the runner to support the tapping bar while driving it out; the molten iron may rush out unexpectedly and burn you.

Do not stand in front of the iron notch when opening it; work from the side as much as possible, even on the first spell, and keep your feet out of the trough. Be especially careful when working on a short, green, hard or an unusually long hole. On changing turn, the keeper going off duty should inform the one coming on as to the condition of the tapping hole. If the hole has been working short or badly, and has not been taking the clay, the keeper should inform the other keeper and tell him how much clay was used on the last stop.

FIG. 13. UNSAFE METHOD OF DRILLING A TAPPING HOLE.
Men standing over open trough on planks, no shield used at tapping hole, men wearing loose, baggy clothing.

Do not cast until the skimmer, trough, runners, shutters, and spouts are dry and warm. Clay, sand, loam, or coke dust in the runners must be dry to avoid "boils" of molten iron. Do not leave pieces of cold scrap in the runners or place damp sand against the shutters or gates. Don't let pieces of wood get under the skimmer dam or drain gates, and bank up the drain or "punch-out" gates on the outside with dry sand. In filling the mud gun before a cast, only one man should do the work if the clay is being fed at the funnel, because if two men are used, one to operate the plunger and one to feed the clay, one of them may be caught by the plunger.

Loading Clay

In loading clay at the funnel do not push it down with your foot; use a stick. However, the gun can be loaded as well and more safely by putting the clay in at the nose of the gun with a rammer. When the gun is loaded, put about 3 inches of dry sand or ground ganister mixed with tar or black oil in the nose, removing enough clay to give room. Wet or sloppy clay may cause an explosion when it comes in contact with hot iron. Do not wet the nozzle of the mud gun. Daub it with black oil after casting, while it is still warm, and again just at cast time. This will keep it from getting wet, and will prevent a "shot" if the nose of the gun is placed in the hole against a stream of molten iron. Oiling the nose of the gun is better than warming it, because if the nose is heated too much or too long the clay will become dry and stiff, and may cause a short hole. If heating the nose is preferred, pouring one or two hand ladles of cinder over it should be sufficient.

When casting do not use cold or wet bars to poke out sand, clay, or loam in the runners or gates or to break a path for the iron. Lift the punch-out or drain gate (Fig. 15) slowly, to avoid a rush of iron, which may cause boiling, and be sure the punch-out bar is warm. Before turning the iron into a ladle see that the ladle is spotted and is all right. Do not fill the ladle within more than 8 or 9 inches of the top, as the iron may be spilled in shifting it. Do not throw large pieces of cold scrap into the ladle before or during the cast, as it may cause boiling or an explosion of the hot metal. It is safer to fill the ladle nearest the furnace first and finish the cast in the ladles at the lower end, for several reasons. One reason is that the gates may be lifted quickly and the operator go away instantly. (See Fig. 16.)

If the iron is run to the bottom ladle first, be sure that all shutters are dry; if to the top ladle first, be especially sure the sand at the gates is dry. When using the pricking rod on an obstruction in the tapping hole, do not throw too much weight on the rod if standing close to the trough. Be sure that the hand ladles and chills for samples or pig-machine wheels are dry. Do not cross iron or cinder runners during a cast except when necessary, and watch your step very carefully; if you have to go in front of the iron notch, get across quickly. Do not step on the crust of hot cinder. Do not flip wet clay into hot iron to annoy or tease a fellow-workman—it is too dangerous.

Stopping the Tapping Hole

In stopping the tapping hole, be cautious when placing the mud gun in the hole. Unless the cinder and iron in the trough lays away from the hole, drain the trough before putting the gun in. Do not put the gun in the hole against a stream of iron unless the nose is warm and dry, as the iron may explode. After the gun is clamped, turn the steam on by the valve at the column, or by means of a long hook open the three-way cock on the gun. There is danger of gas bursting out or cinder being thrown back when the first clay is shot in. Care must be exercised in stopping the hole after the first shot, as the pressure in the furnace and the suction of the plunger may throw the clay back in the barrel of the gun and a burst of gas or slag follow.

It is safer to feed the clay into the gun with a shovel rather than to stand close to the hole and trough, unless one is expert at throwing the balled clay into the funnel from a safe distance. (See Figs. 17 and 18.) As stated before, use a stick—not your foot—to poke clay down into the funnel. While stopping the hole do not stand so that all your weight is on the sheets covering the trough, and watch for the exhaust steam. Do not put the wind on until the hole has stopped taking clay freely, and after

FIG. 14. SAFE METHOD OF DRILLING A TAPPING HOLE.
Steel plate over runner, shield in point of tapping hole, men wearing proper clothing, air jet used to clean tapping hole.

the hole is stopped leave the gun in it with steam on until the clay has set; this may prevent a breakout at the tapping hole between casts. If men are changing tuyères or plates, never throw or turn water into the funnel of the mud gun or use wet clay before the hole is entirely stopped, as gas may blow out on the tuyère men. Step away from the gun for a moment when shooting water into the hole.

In putting water in the skimmer trough at "rid-up," do not stand near by with a short nozzle to turn the water in (Fig. 19). If the water strikes hot slag, the steam may scald you, and if it strikes a pocket of hot molten iron there may be an explosion. It is safer and just as effective to use a pipe, 15 feet or more long, turned down at the end (Fig. 20). If it is necessary to break up crusts or skulls in the trough before turning water on, don't use a cold or wet bar. When handling hot scrap or slag use tongs or a hook whenever possible, and be careful in breaking or barring slag and scrap to avoid flying pieces, falls, or dropping material on to your feet. Before throwing scrap or cinder into a car, be sure there is no one in it and that the pieces do not project over the end or sides of the car where they may fall or be pushed off.

Under Blast Precautions

Never tighten the keys on the tuyère stocks or caps, or take up slack on the bridles when the blast is on unless you are directed to do so by the foreman. Watch for tight bridle springs or split stock hangers, and don't screw up the nut on the bridle until the spring is tight. Do not start to loosen the monkey or stock bridles, hangers, keys or caps until the blast if off and the gas is drafted back. Wear goggles when watching the peep sights during a cast or check, and do not open the peep-sight plug until you are sure no one is in line with it. Don't try to blow coke out of the eyesights until the blow pipes have had time to cool. Know where the hose and water valves are situated in the cast house, as they are needed quickly at times. When playing the hose on tuyères, blowpipes, or the furnace jacket, stand behind a column as much as possible, or to one side, as they may burst or burn through.

In case a tuyère bursts or a blowpipe burns out, do not work about them unless thoroughly familiar with the danger. Work to one side as much as possible when dropping blowpipes, claying up, and changing tuyères, as cinder, coke or gas may blow out. The tuyère opening should always be firmly plugged with clay as soon as the blowpipe is dropped. Never work about an open tuyère or plate when water or wet clay is being put in the tapping hole. Watch for hot bars, blowpipes, and scalding water or steam. Do not put up the blowpipes after a shut down until the foreman orders you to, for unless the blowing engine is turning over it might cause an explosion. Don't look into a blowpipe when cutting out clay after a stop.

When "botting up the monkey," or plugging the cinder notch, wear goggles or a mask and long leather gloves; be sure of your footing, and always use the shields provided. Work from the side of the cinder notch as much as possible when opening it, and, when breaking cinder in the runner during a flush, keep out of line with the cinder notch and be careful the cinder does not splash on your feet. Cinder will splash farther than iron. Keep as far away as possible when throwing coal in the cinder runners. It is just as well not to throw coal into stiff cinder, as it does not greatly help matters.

Do not throw damp or wet rubbish in the cinder ladles, and always examine them for water or dampness and dry them out with cinder before flushing or casting, because a damp ladle may boil or explode when being filled. Keep away from the granulating pit when the skimmer trough is being drained or when you think iron is coming over the cinder dam. If it is necessary to plug a cinder ladle with clay, always place a sign, or station a watcher before going into the ladle. Be sure there is no one in a car or ladle before throwing rubbish into it.

Reporting Abnormal Conditions

Be prompt to report anything abnormal or unusual about the furnace—for instance, the blast pressure becoming

KILLED AT BLAST FURNACE

Sault Ste. Marie, Ont., Jan. 24.—While engaged at his work at the blast furnace of the Algoma Steel Corporation yesterday Emil Provost, an unmarried Frenchman, twenty-four years old, whose home is in Ottawa, met his death while tightening up a door of one of the furnaces while the pressure was on. He had resided in the Soo only about one month.

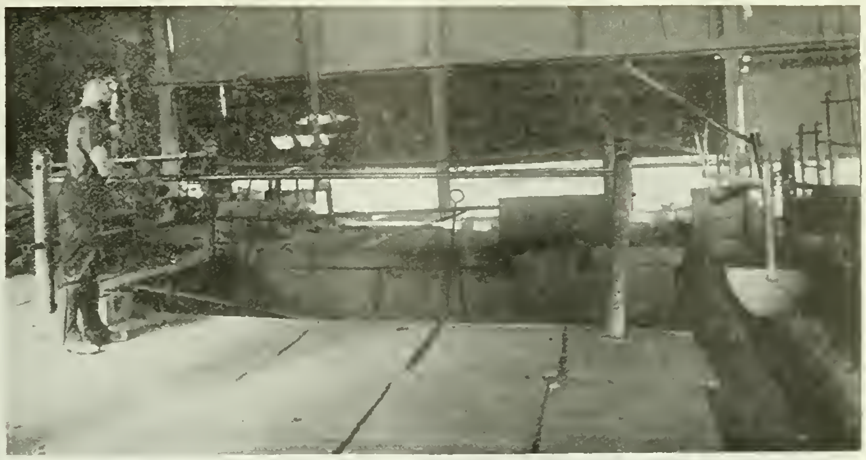

FIG. 16. MODERN RUNNER GATE OPERATED BY A CABLE AT A SAFE DISTANCE FROM THE RUNNER. ONLY A PART OF THE CABLE IS SHOWN.

FIG. 15. SAFE METHOD OF OPERATING PUNCH OUT GATE. Note the mask worn to protect man from splashes.

high or low; hanging, tightness, or slipping of the burden, cold or dirty cinder; sloppy, dead, or leaking tuyère; gas lighting on the bosh or about the mantle; hot spots on the shell; delays in filling the

FIG. 17. UNSAFE WAY TO STOP TAPPING HOLE.
Helper is using his hands and standing too near tapping hole.

furnace or in spotting iron or cinder ladles; wind and gas leaks; or signs of a break out, such as steam or gas coming from about the jacket, columns, or pavement, the water getting hot or steamy in the discharge from the hearth or bosh jacket or on the jackets, or the pavement or columns getting unusually hot. Especially, report promptly any signs of the cooling water supply becoming slack. Neglect of these points oftentimes leads to unnecessary hard work and danger from "messes," breakouts, slips, burned tuyères and blowpipes, or explosions. The foremen are looking for these signs also, but one man may not see all of them.

The Hot-blast Men

Be careful that the gas or blast is not turned into or gas drafted back through a stove that is being cleaned. Do not open or close any doors or valves or remove any signs or locks on such stoves until the foreman has told you to do so. Before turning gas into a stove, warn any well-bottom cleaners working about the doors, as it may flash back when it ignites; and be sure that the chimney valve is open. If you think that the stove is not hot enough to light the gas, put a large bunch of burning waste at the gas door or provide other means to ignite the gas. Don't stand by the burner after turning gas into the stove; step away quickly. At times the gas will not light until it reaches the top of the well or combustion chamber, and it is then likely to light explosively and puff out through the burner and air doors. Be especially careful when you are turning on gas from a furnace just blown in or from one shut down on account of leaky "bronze" (tuyères, coolers, bosh plates, cinder monkey, etc.). In case of doubt always use burning waste; don't let the stove fill with gas and then try to light it. If the stove does not light, shut the gas off and start over again, using burning waste.

Before you blow off a stove, warn men to keep away from the blow-off valve, and especially warn them away from the blow-off door if the stove is being shut down for a leaky tuyère, as the gas may be very explosive. Be sure that the blast is on the new stove before shutting the cold-blast valve of the stove being taken off. Don't let the hot-blast valve drop sharply on to its seat, and don't let the blast slam the chimney valve into place; set the valves easily by hand. Open the cold-blast valve slowly to avoid racing the blowing engines.

In case of the blast stopping unexpectedly from any cause shut the mixer valve on the by-pass at once, then close the cold-blast and hot-blast valves as soon as possible. Never forget to close the mixer valve before checking or shutting down the furnace, beginning a cast, or stopping the blowing engine. To forget to do this may cause an explosion that will wreck the mains and engines. When it is necessary to take the stoves off during a shut-down to "change bronze," or for a short stop, be sure the burners are closed tightly. When ready to start the furnace and bring the gas down, never turn the gas into the stove until the blower has given the signal. Be sure that the explosion doors or bleeders on the gas mains or dust catcher are closed during a shut down; if any air gets into the mains there is always a chance of an explosion. Whatever way the blower tells you to handle the top bleeder, whether to keep it open or shut during a shutdown, always follow his order to the word. Many serious furnace accidents are caused by operating bleeders and gas valves other than in the way ordered. The least change from orders may cause a terrific explosion. If the gas is "wild" in drafting it back in one stove at a shutdown, draft back through an additional stove at once.

Keep away from the dust legs and manhole covers on gas mains, from gas burners and air inlet doors, when the furnace is sticking and liable to slip. Be careful when you open an air door to see how the gas is burning; if too much gas is turned on, or if the checkerwork is dirty, the gas may flash back into your face. Keep and warn others away from these places; no one should handle burners, doors, or valves unless directed by the stove tender. Do not tighten any

FIG. 18. SAFE WAY TO STOP TAPPING HOLE.
Helper is using shovel and standing away from the trough and the tapping hole.

thumb or other nuts on doors or blow-off valves when the stove is on blast; you may be killed or injured by the bolt breaking. Watch the water on the hot-blast valve and seat, because water leaking into the stove may cause the furnace to slip or get cold; it will then be more dangerous. Report any gas leaks about the burners or mains; do not let them leak unnecessarily. When the millwright is examining the chimney valve for leaks do not change the stove from blast to gas. When the hot-blast valve and seat are being inspected be sure the chimney valve is kept open and the gas turned off.

The Stove Cleaners

Before entering a stove to clean it, lock the cold-blast valve and gas burner shut, fasten the chimney valve open, and either block the hot-blast valve in its seat or disconnect the cable from the stem, or lock the windlass, and attach danger tags; be sure these things are done. Stop any leaks about the burner with clay, as even a small leak may allow considerable gas to drift into the stove. It is always safest to close the burner door, but if this can not be done for any reason, turn the burner on its seat, away from the door or seal it off with a blank. When ladders must be used to get into a stove through the dome manhole do not try to carry tools up or down the ladder, use a hand line. (See January 25 issue, Figs. 8 to 10.) Keep away from the well of the combustion chamber, and do not sit on the bridge wall between the well and the checkerwork; the wall may give way. Boatswain's chairs for cleaning, tearing out, or repairing the well lining should be supported by tackle attached to the top of the stove shell when possible, and the chair, rope and tackle tested to double a man's weight before use. Anyone working in a boatswain's chair should wear a life belt attached to the chair-sling block. Do not use a torch inside a stove; use an electric light on a standard insulated extension cord and have an electrician make all connections.

When it is necessary to clean checkerwork from the bottom or to clean out under the arches, keep under the arches as much as possible to avoid bruises from falling brickbats, clinkers, or tools. It is best never to enter the bottom until everyone is out of the top. Always wear goggles when inside a stove and do not remove the locks from the valves until everyone is out and the manholes are closed. In cleaning flue dust from the bottom of a stove be careful to avoid burns: the dust is usually hot and easily runs into one's shoes. Notify the stove tender before opening the cleaning, air-inlet or blow-off door to clean the well from the outside, and have him turn the gas off enough to avoid any danger of flame puffing back through the door at which you are going to work. In case the furnace is hanging, stop work until it slips, and keep away from the cleaning door. In loading barrows with hot cinder or dust do not fill them so full that they will run over; handle them carefully, and warn others to keep out of the way. Bars and cutters used in cleaning wells should be handled with crossbars when withdrawing them from the stove. Keep away from the doors when gas is being turned in the stove.

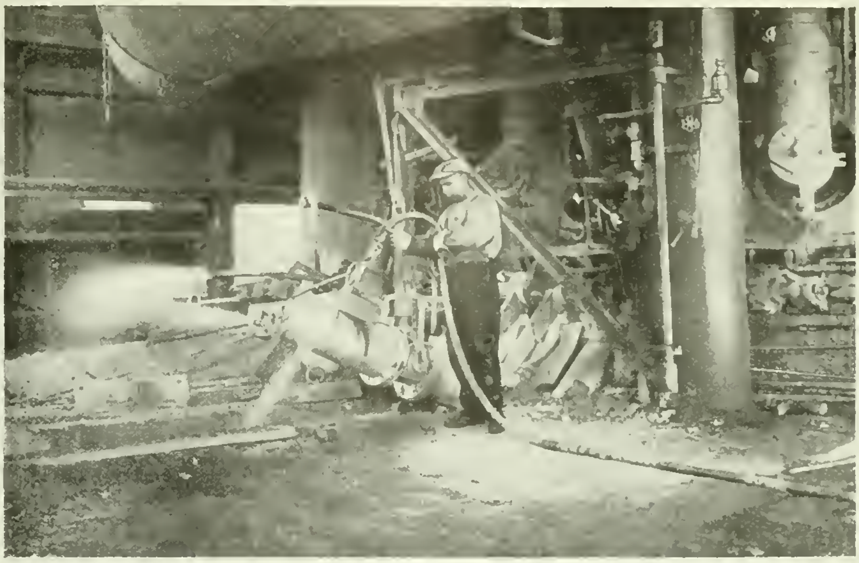

FIG. 19. UNSAFE WAY OF WETTING DOWN TROUGH AT "RID-UP."
Short nozzle on the hose, man standing close to trough where he is exposed to an explosion of hot metal or steam.

The Dust-catcher men

Empty the dust catcher regularly; if you let it get filled and the furnace slips, there may be an accident. Notify the foreman when the car is full and if the car is not moved promptly and an empty one spotted. Never dump the dust catcher when the wind is off the furnace or when the furnace is hanging or liable to slip unless you are doing it under the orders and directions of the foreman or superintendent. In dumping dust legs, dust pockets, or dust catchers be sure there is no one underneath to get burned, and warn men against approaching, as the dust may fly and burn them. Be careful in cleaning up dust and never step on it, because it will run like water when hot, and burn you severely if it gets in your shoes. Be cautious in playing a hose on hot dust, as it sometimes explodes or flies. Do not clean up under the dust catcher unless you have notified the foreman and he has told you to go ahead; the bell may be forced open by a slip or by being overweighted and the dust may burn you. For the same reason never go into a dust car after it is spotted under the dust catcher; pack the doors before the car is placed. Turn the water on full before you open the bell, and water the dust thoroughly when dumping the dust catcher. Don't fill the car with hot dry dust and then turn the water on; it will soak down slowly, and the contents may explode. Always place a card on the car so that the unloaders will know they are handling flue dust.

In a recent issue of *The Electrician* some new facts which illustrate the great impetus given to the construction of electric steel furnaces are reported. Since the outbreak of war over 100 installations are known to have been put in, and the total number in the world now approaches 300, which is about twice the number existing in 1913. The United States is credited with constructing 50 last year and Great Britain with 30 since the war began.

MACHINISTS' INSTRUCTION COURSE—XIII.

By J. Davies.

THE introduction of modern screw-cutting lathes with special appliances and attachments, has eliminated much of the calculation that used to be necessary for such work. Every capable lathe hand, however, ought to be able to make any necessary calculations relative to such work. The system of calculation as arranged by the writer is designed to carry the student forward in easy stages, and no previous knowledge of mathematics is required except an elementary knowledge of arithmetic.

Pitch of Thread

The pitch of the thread is the distance from the centre of one thread to the centre of the next, except in the case of a double or triple thread, Fig. 51; in

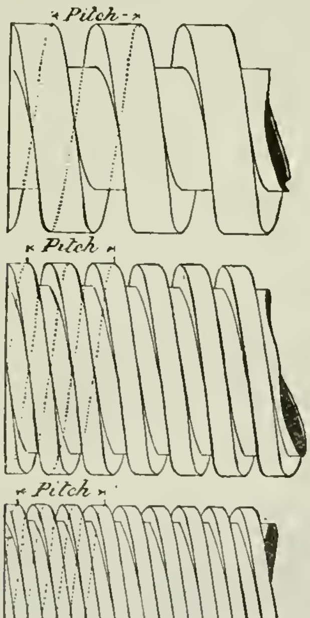

FIG. 51.

any case the pitch is represented by the distance the screw moves endways in one complete revolution.

(1) Put down the pitch of the thread to be cut in the form of a fraction. An easy way to express the pitch of any given thread is to draw a horizontal line thus ——— placing the number of threads below the line and the number of inches above the line, the resulting fraction will always be the pitch of the thread.

Example: Pitch of 6 threads per inch $\frac{\text{Inches}}{\text{Threads}} =$ 1-6 pitch, and so on for all even pitches. In cases where there is a fractional number, multiply both inches and threads by the least number that will bring them to a whole number.

Example: Find pitch of $6\frac{1}{4}$ threads per in. Proceeding as before $\frac{\text{inches—1}}{\text{threads } 6\frac{1}{4}}$ Multiplying by the least number that will bring them to a whole number $= \frac{1}{6\frac{1}{4}} \times 4 = \frac{4}{25}$ in. pitch. A little more difficult one.—find pitch of $3\frac{2}{3}$ threads in $1\frac{3}{4}$ in. $= \frac{\text{inches } 1\frac{3}{4}}{\text{threads } 3\ 2\text{-}3} \times 12 = \frac{21}{44}$ in. pitch.

If the pitch is given in decimals bring it to a fraction by placing noughts or cyphers under each decimal figure and 1 under the decimal point, thus: pitch of decimal .75 in $= \frac{75}{100}$ or $\frac{3}{4}$ in. and so on—pitch of decimal .125 in. $= \frac{125}{1000} = \frac{1}{8}$ in. and so on. Having found pitch of screw to be cut, find pitch of leading screw in the same way.

A Matter of Ratio.

The whole principle of gearing up a lathe for screw cutting is one of ratio or proportion. The ratio of the driving to the driven wheels must be the same as the pitch of the screw to be cut is to the pitch of the lead screw. Suppose the thread to be cut was the same pitch as the lead screw, then it is evident that the work must make the same number of revolutions in the same time as the lead screw.

Example: Pitch of screw to be cut is $\frac{1}{4}$ in.; pitch of leading screw $\frac{1}{4}$ in.—find ratio. Rule: Invert or turn upside down pitch of leading screw in inches, and multiply, the reason for turning the fraction upside down is because the wheel with the least number of teeth makes the most revolutions. $\frac{\text{Inches}}{\text{Thread}} = \frac{1}{4}$ invert pitch of leading screw and multiply $= \frac{1}{4} \times \frac{4}{1} = \frac{4}{4}$ ratio. After finding ratio, a number of different sets of gears can be found by multiplying the ratio by any number we choose, but care must be taken to multiply both numerator and denominator by the same figure so as not to alter its value.

Find wheels to cut 4 threads per in. leading screw 2 threads: thread to be cut $= \frac{\text{inches}}{\text{threads}} = \frac{1}{4}$. Leading screw $= \frac{1}{2}$ in. pitch: invert leading screw and multiply $\frac{1}{4} \times \frac{2}{1} = \frac{20}{40}$.

Find wheels to cut 3 1-7 threads in 2 1-5 inches with a lead screw $\frac{1}{2}$ in. pitch?

$\frac{\text{Inches}}{\text{Threads}} = \frac{2\ 1\text{-}5}{3\ 1\text{-}7} \times 35 = \frac{77}{110}$. Invert lead screw pitch and multiply $= \frac{77}{110} \times \frac{2}{1} = \frac{154}{110}$, or $\frac{77}{55}$ wheels required, or bringing the fraction down to its lowest dimension we have $\frac{154}{110} \div 22 = \frac{7}{5}$ or $\frac{70}{50}$ from which any number of different sets of wheels may be obtained.

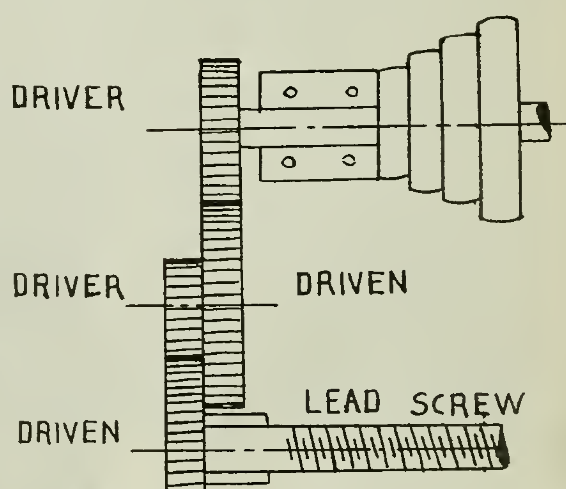

FIG. 52.

Compound Gearing

Sometimes it happens that the number

of teeth in a gear wheel would be too large to employ a single train of wheels; in this case compound gears must be used. Here is an example that would require compound gears. To cut 24 threads per inch with a lead screw, two threads per inch. Proceed to find ratio as before: $\frac{1}{24} \times \frac{2}{1} = \frac{2}{24}$ ratio. Take the numerator of the ratio, which is two, and find any two numbers which, multiplied together, will equal that number. Then take the denominator of the ratio, which is 24, and find any two numbers which, multiplied together, equal 24 $\frac{2}{24} = \frac{2 \times 1}{12 \times 2}$. We have now divided the ratio into four factors of equal value, which will enable us to use compound wheels. We can take any figure in the numerator or denominator and multiply, add, or subtract at will, as long as we do not alter the relative values in adding or subtracting; the amounts added or subtracted must be the same proportionate amounts of each, such as 1-3 or 1-4 or 1-5, and so on as the case may be. Take the first two figures in our example and multiply each of them by ten $= \frac{2}{12} \times 10 = \frac{20}{120}$. Take the second two figures and multiply by $50 = \frac{1}{2} \times 50 = \frac{50}{100}$

Wheels required, therefore, are

$$\frac{20 \times 50 \text{ Driving wheels.}}{120 \times 100 \text{ Driven wheels.}}$$

The two top wheels are driving wheels and the two bottom wheels are driven. The sketch, Fig. 52, illustrates the position of the wheels on the lathe.

It is required to find gears to cut 16 threads per inch—lead screw ½ in. pitch? $\frac{1}{16} \times \frac{2}{1} = \frac{2}{16} = \frac{2 \times 1}{4 \times 4} = \frac{20 \times 30}{40 \times 120}$

Proving the Wheels

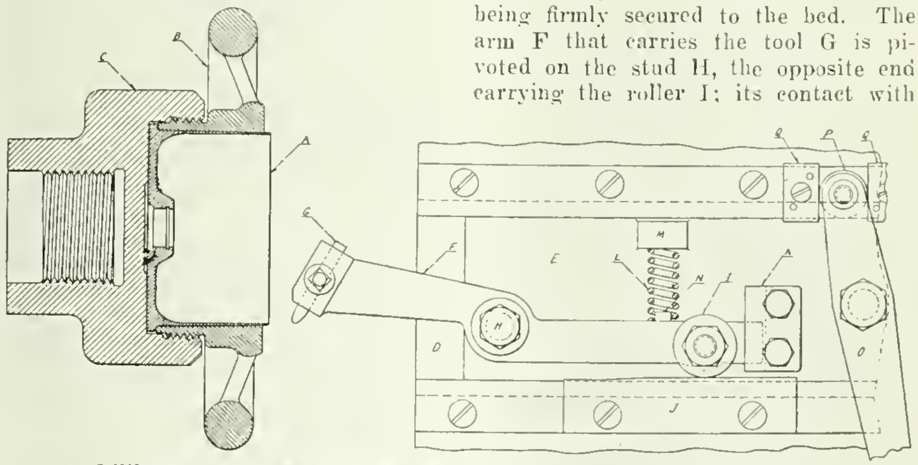
To prove the wheels, multiply all driven wheels together; then multiply all the driving wheels together and divide the driven by the drivers. If the wheels are correct, you will get the same ratio or proportion as exists between the pitch of the leading screw and the pitch of the screw to be cut. Take the above example—driven wheels. $40 \times 120 = 4800$; driving wheels $= 20 \times 30 = 600$. $4800 \div 600 = 8$. Ratio of wheels between driver and driven = 8 to 1.

$$\frac{\text{Threads to be cut}}{\text{Threads on lead screw}} = \frac{16}{2} = \frac{8}{1} \text{ ratio required.}$$

MACHINING 4.5 SHELL CARTRIDGE CASES

By J. Hamilton

THE delicate nature of the brass cases that contain the propellant for the smaller size shells offers every means of displaying originality in the development of appliances for their rapid and economic handling while machining. Following the tapering operation on the 4.5 in. cases, it is necessary to remove some of the metal from the interior of the mouth, and retain at the same time a uniform thickness of metal at all points on the circumference. How one plant performs this operation is described and illustrated by the accompanying sketch.



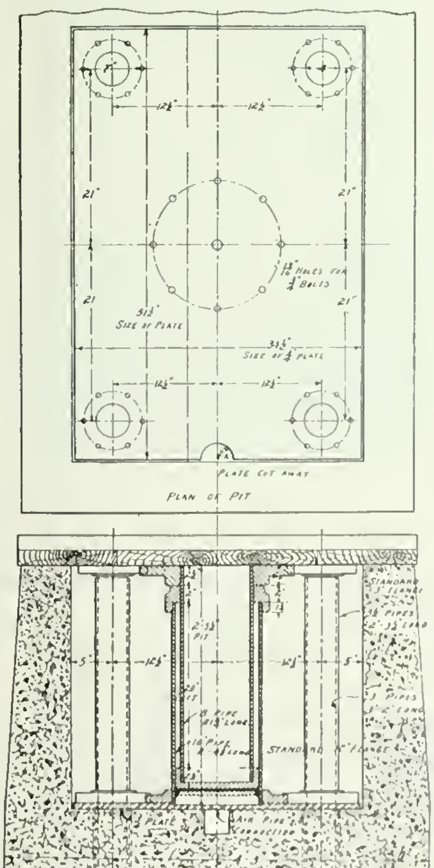
DEVICE USED IN MACHINING MOUTH OF 4.5 IN. CARTRIDGE CASES.

The cartridge case A is placed in the special hand-wheel B, the bore of which is machined to an accurate fit for the external taper of the case. The boss of this wheel is threaded to fit the chuck speed lathe. By this method the head of the case is forced against the inner face of the chuck, with the outer end running true. With the machine operating at high speed, the cutting is rapidly performed. A special block E was made to operate in the slide D, this being firmly secured to the bed. The arm F that carries the tool G is pivoted on the stud H, the opposite end carrying the roller I; its contact with the cam J governing the shape of the case bore. The plate K acts as a support for the extended tail of the tooling arm F. Contact between the roller and the cam is maintained by the action of the spring L. The forward movement of the tool is derived by means of the lever O, the short arm carrying the roller P, operating between the two blocks Q, secured to the gib of the slide.

ELEVATING PLATFORM

By E. T. S.

ALMOST every manufacturing plant has a lifting proposition somewhere or other, in which the lifting platform style would be the ideal thing. The method outlined in the following may be very simply arranged in plants where compressed air is employed, for the reason that practically the whole outfit is made from standard pipe fittings. The elevating platform, shown in diagram, shows the simplest form of this arrangement with a single piston. We have in use at our plant several of these elevators which have a second piston, that is to say, the telescopic pipes comprise three pipes instead of two as shown. The base of the outer pipe is simply a pipe flange which is bolted to the base plate covering bottom of pit; a hole in the centre provides the air inlet. The top end of this outer pipe is threaded on to a reducer coupling bored out to suit size of inside pipe. The bottom end of the inside pipe is fitted as a piston with a single leather packing ring, and at the top end is a standard flange to which is attached the elevating platform. If the platform is large, it is necessary to provide guides in order to steady ascent and descent. For these guides we have four pipes 3½ inches diameter, into which slide four pipes 3 inches diameter. The larger pipes are fitted with standard flanges, and bolted to bottom



ELEVATING PLATFORM DETAIL.

plate, while the smaller pipes are similarly fitted and bolted to underside of platform. The whole is built up in a concrete pit having the platform ground level, so that trucks can be run on easily, and is controlled by a standard 3/4 inches four-way valve. It is a low-priced elevator, gives good service, and hard to put out of service.

TWO USEFUL KINKS

By John Thorn.

TAKE an ordinary monkey wrench, drill two holes in the jaws for 1/4 in. steel pins, cut a slot in the upper jaw to admit an ordinary cutter wheel, and another slot 3/8 inches wide in the olwer jaw for a roller; a cutter wheel can be used instead of the roller if desired. This converts the wrench into a passable iron pipe cutter, Fig. 1. By removing the pins and cutters, the wrench can be used as usual.

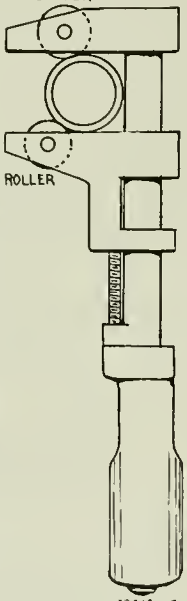


FIG. 1.

Another useful idea is shown in Fig. 2, this being a pump for testing pressure gauges. The body is a piece of 1 1/2 in. heavy brass pipe, threaded at each end with standard pipe threads; a light cap is put on one end, while on the other end is threaded a heavy cast iron cap drilled in the centre and tapped for an ordinary 5/8 in. bolt. A long stem, with a T-handle, is threaded nearly the whole length as shown. This stem is a piece of 5/8 in. iron or brass rod which, with two iron washers, nuts and a cup leather, forms a plunger. A test gauge and a gauge to be tested are attached to the elbows at A and B.

Before testing or attaching the gauges, place the lower elbow in a dish of water and leave the pit cock at B open and the one at A closed. Screw the plunger down as far as it will go, and then turn it back to the upper position with the elbow under the surface of the water; this will fill the pumps with water. Attach the gauges, open the pet cock and turn up on the T-handle, when a pressure of several hundred pounds can be secured with ease. The reason for using brass tube is because the inner surface of brass tube is usually much smoother than iron.

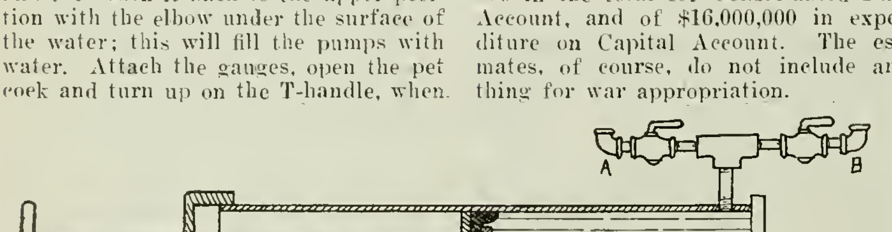

FIG. 2.

When a gauge is either weak or strong, all that is usually necessary to put it right is to remove the pointer and dial, oil the inner mechanism with a little coal oil, using a tooth brush (be sure none of the bristles are left behind), and replacing the dial and pointer so that it will just rest against the pin. Of course, if any cog or sector teeth are broken, or the spring tube is leaking, that is another story; but nine times out of ten all that is wrong is the pointer. The writer remembers once finding fine pressure gauges in a plant, all of which had been discarded as useless, and in less than an hour had tested all of them, moved the pointers, and after testing again, they were absolutely correct with the test gauge. Gauges should not be placed where they will become hot, and steam should never be allowed to enter the spring, either of which conditions will ultimately destroy its usefulness.

FEDERAL GOVERNMENT EXPENDITURES

THE main estimates for the coming fiscal year, tabled in the House of Commons, Ottawa, by the Finance Minister, provide for a total expenditure of $203,472,756, of which $182,359,215 is on Consolidated Fund account, or for the ordinary expenses of administration. The total amount for capital expenditure is $21,113,546.

There is a very considerable sealing down of expenditures for public works and for railways and canals on both Consolidated Fund and Capital Account. The biggest increase is the interest on the public debt, which jumps from $37,000,000 to $54,000,000. The war is also responsible for an increase in the pensions bill by $5,398,000. The amount required for the coming year is $8,763,000. There are scarcely any new public works authorized. There is a reduction of $11,026,162 in the total expenditure to be voted for public works under Consolidated Fund Account, and of $2,482,000 for public works on Capital Account. The reduction on railways and canals expenditure on Capital Account is $12,216,756.

As compared with the estimates of last year there is a reduction of $1,500,000 in the total for Consolidated Fund Account, and of $16,000,000 in expenditure on Capital Account. The estimates, of course, do not include anything for war appropriation.

Some of the Chief Items

The main items on Capital Account for railways are $6,500,000 for construction and improvements of Government railways, $200,000 for Welland Ship Canal construction (as compared with $4,500,000 last year), $600,000 for canal inspection, $1,600,000 for the Quebec Bridge, and $3,000,000 for the Hudson Bay Railway. The main items on capital account for public works are $2,000,000 for the restoration of the Parliament Buildings, $1,000,000 for St. John harbor improvements, $1,000,000 for the drydock at Quebec, $1,000,000 for Toronto harbor improvements, $750,000 for Port Arthur and Fort William harbor improvements, and $1,000,000 for Victoria, B.C., harbor improvements.

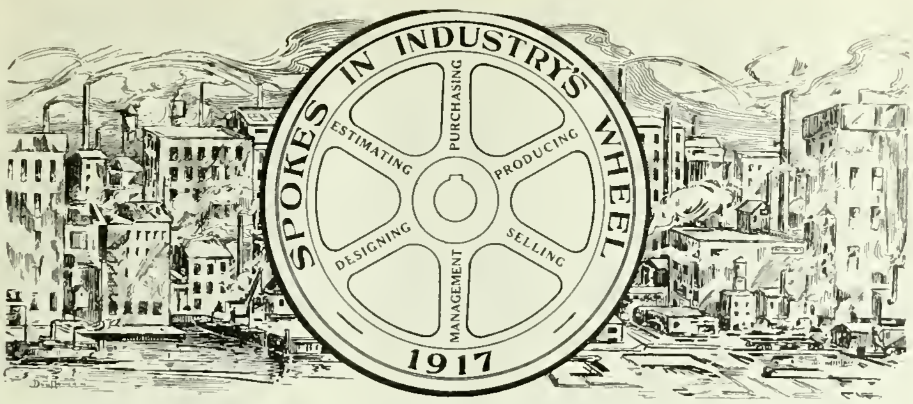
The vote for Federal aid for agricultural instruction in the provinces under the Act of 1912 is increased to $1,100,000, or by $100,000. The Immigration Department vote stands at $1,215,000, a decrease of $359,000 as compared with last session.

I. C. R. War Business Increase

The recent big increase in traffic on the Intercolonial consequent largely upon war business is mainly responsible for increasing the last year's vote for Government railway working expenses from $13,850,000 to $25,000,000 for the coming year. Supplementary estimates are, of course, still to come. If an election impends, a long list of further votes for public buildings and for rivers and harbors may be expected.

Silvering Brass for Lacquering.—It often happens, in finishing ornamental work, that silver bands or reliefs are needed, the thickness of the silver, of course, being a minimum. To make a good and efficient solution for the purpose, dissolve 1 oz. of good nitrate of silver in a quart of distilled water, and in a separate vessel make a semi-saturated solution of hyposulphite of soda. Add sufficient of the hyposulphite solution to the nitrate of silver solution to throw down the silver as a brownish precipitate, agitating the liquid; then add, drop by drop, sufficient of the hyposulphite to re-dissolve the precipitate, and after this is secured add a slight excess of hyposulphite. Store in black or other non-actinic glass bottles, well corked. To use, apply to the clean metal with a sponge or brush, and rinse off with clean water, and dry thoroughly before lacquering.

THE resistance of a material to fatigue depends entirely on the homogeneity of its physical equilibrium, and is proportional to the toughness and the elastic limit. Any outward conditions that tend to alter the state of the homogeneity more or less have a weakening effect on the material, and in extreme cases cause ultimate failure. When a metal is subjected to repeated alterations of stress a series of slips take place along the gliding planes of the crystals. The slipping action, which is characterised as fatigue, continues backwards and forwards until actual rupture takes place.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

WILLIAM J. McCALLUM

SOME men are born to fame, while others have fame thrust upon them, Neither of these conditions apply to our "Spoke" this week, however, as the reputation which he enjoys in his official capacity of chief fengineer and superintendent of the Chapman Double Ball Bearing Co., Toronto, has been worked for, and duly earned from the day when, as a school boy, he decided that his summer holidays could be better employed picking up the rudiments of a machinist's trade, than by whiling away the sunny hours in care-free indolence. That this industrious trait, which thus early showed itself, was not of transient nature, can be vouched for by many friends of our "Spoke."

William J. McCallum, sometimes Billy, and always Mac, is a Canadian by birth and parentage, although when occasion demands it, he exhibits a justifiable pride in the fact that one of his ancestors came from the land of "hoots," heather, and highland dew. This was 'way back in 1832,, however, so that, with the exception of his name and a characteristic persistency in applying himself to the question of the mometn, Mac, being a lifelong teetotaler, has very little left to indicate that his forebears wore the kilt.

Mac first saw the light of day at Woodbridge, York County, Ont., on Nov. 17, 1879, and towards the termination of his public school days, spent some weeks each summer with the Toronto Electric Works, Toronto. School days came to an end, however, and the serious work of life began with the Diamond Machine Tool Co., the time spent there being also occupied with studies at the Technical School, followed later by a Correspondence Course in mechanical engineering. Subsequent experience with the John Abell Co. was followed by two years in charge of the fitting and lathe department of the Dodge Mfg. Co., at the early age of 24 years. The experience gained here in transmission machinery and equipment was of particular value in view of ultimate developments.

After a subsequent stay with the American Abell Co., Mr. McCallum, in 1907, secured the position of chief draftsman with the Chapman Double Ball Bearing Co., with whom he has remained ever since. His experience, therefore, has been secured entirely with Toronto firms, a fact which is mutually creditable.

Mr. McCallum's work in connection with the ball bearing industry in Canada constitutes a record of consistency.

WILLIAM J. McCALLUM.

persistency and efficiency, of which few other lines of effort offer any comparable instances. Taking up this work at a time when antifriction bearings and similar power saving devices were under a cloud of disfavor due to unwise exploitation, the pioneer period of his work was truly uphill. Experience in all new lines of manufacture is always fraught with more or less trouble, and in just so quickly and efficiently as this experience is obtained and turned to good account, so the progress of any new business is determined. It is interesting to know, therefore, that the rapid and continual growth of ball bearings as regular items of factory equipment dates from the time of Mr. McCallum's connection with the business; all of the types of Chapman bearings now on the market having been re-designed by him in accordance with results obtained in every branch of Canadian industry. Pulp mills, steel mills, cotton mills, lumber mills, machine shops, quarries, brick works, clothing factories and arsenals are but a few of the numerous fields into which our subject has ventured in support of his present efforts.

The large field for observation thus obtained resulted in a due appreciation of possibilities in other efficiency equipment besides ball-bearings. The Universal elevating truck now being marketed by his employers is the direct result, in considerable measure, of Mac's inventive ability, which has had full play since munitions manufacture became a quasi-staple industry of this country; a popular type of banding press and considerable accessory equipment for shell manufacture are personal products.

Close application to work has somewhat restricted our friend's opportunity for travel, although he admits a desire to plant his foot on his native heath and conjure up scenes of McCallum More and Roderick Dhu in the midst of their native hills. The larger industrial centres of the States, however, have been frequently favored with his presence of recent years, while several remote parts of Quebec Province and Northern Ontario have been visited in the course of missionary work—for ball bearings, of course—which leads one to remark that Billy adheres to the faith of his fathers and is a staunch Presbyterian.

His views on the subject of religion are shared by his wife, who became Mrs. W. J. McCallum sixteen years ago. Their family consists of three daughters and one son, and their residence in Toronto is at 62 Mountview Ave.

Home life claims the most of Mr. McCallum's affections to the detriment of politics and allied activities. He is quite free of any political bias; an intense admiration for and loyalty to the British Empire being the most prominent streak in this direction. The same absence of sectarian views is evidenced in his attitude toward affiliations and societies; the "Brotherhood of Man" typifies his outlook on humanity, although in some quarters the view is rather gloomy.

His outlook on the question of engineering is not gloomy, however, and the joy of future competition will be welcomed as bringing further fields to conquer. In this respect Mac is very frank in expressing his indebtedness to technical journalism of all kinds. "Starting life on the level with the rest of us, uninfluenced and unaided, no man, who is willing to work and take advantage of present day educational facilities need be lacking in that education which contributes so much to success. A thorough technical training imparts a lasting demand for technical knowledge of current developments, and in this direction lies what I consider one of the outstanding features of successful trade journalism."

MACHINING FLY-WHEEL ON AUTOMATIC TURNING MACHINE

Herbert's Monthly.

IT may be generally stated that all turret lathe chucking work is suitable for production by automatic turning machine methods, provided it is within the

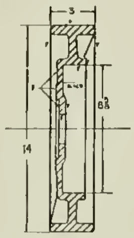


FIG. 1.

capacity of the machine as regards length and diameter, and that the articles required are in sufficiently large quantities to warrant them being made automatically. The fly-wheel shown in Fig. 1 is, therefore, an ideal piece of work, and will afford a good instance of an efficient lay-out of automatic turning machine tools. The fly-wheel is an iron casting.

At the first operation, shown in Fig. 2, the casting is gripped under the rim by special jaws in an 18-in. special chuck, the large bore being inwards, and the casting is set back against the jaws themselves; in the chuck is a standard steady bush and liner. In the line drawing, Fig. 2, the various tools have been numbered to facilitate reference to the operations.

1.—This is a standard facing tool, carried in the back tool post, and rough faces the edge of the rim.

2.—This is a standard slide facing tool, carrying three cutters for facing the portions which are inaccessible from the cross slide. The direction of traverse is shown by the arrow, and the slide facing tool is operated by the pusher, which is clamped in one of the tool slots of the back tool post. It will be noted that four tools are, therefore, cutting simultaneously, making the facing a very rapid operation. During the facing operations the turret is held in position by a retaining cam.

3.—This is a standard combination tool, carrying a boring bar for the 2-in. hole, a second boring and facing tool

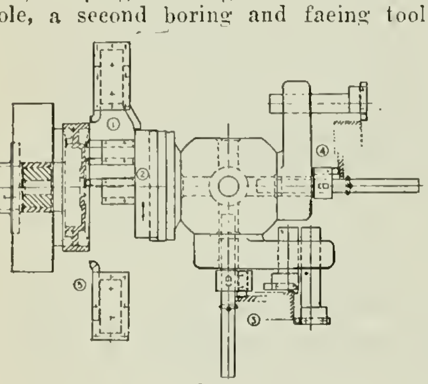

FIG. 2.

for the spigot recess, a rough turning cutter for the outside of the rim, and a radius cutter for the edge. A positive drive to the cutter head clamped on the boring bar is obtained by another turning tool holder in one of the empty holes, but this is not shown in the drawing.

4.—This is another combination tool, which carries a finish boring bar for the 2-in. hole, a sizing cutter for the spigot, and a finish turning cutter for the outside. The finish turning cutter and a single point boring cutter are arranged so that they have ceased cutting before the sizing cutter for the spigot comes on to the work. This is done so as not to disturb the sizing cut.

5.—This is a finish facing cutter for the edge of the rim, carried in the front tool post, and operated simultaneously with 4.

At the second operation the fly-wheel is gripped by the finished outside dia-

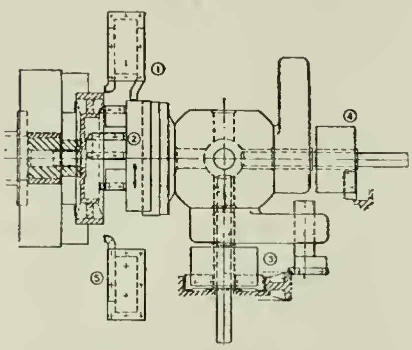

FIG. 3.

meter in soft jaws and located true by a special steady bush, which fits in the spigot recess machined at the first operation. As this recess is shallow, the steady bush is made from case-hardened mild steel, and, therefore, has to be bushed with a bronze liner, otherwise the boring bar would gall up. (See Fig. 3.)

1.—This is a standard facing tool, carried in the back tool post, and rough faces the edge of the rim.

2.—This is a standard slide facing tool, carrying four cutters for facing the portions which are inaccessible from the cross slide. The direction of the traverse is shown by the arrow, and the slide facing tool is operated by the same pusher as used in the first operation, except that it is turned round, with the offset on the other side. It should be noted that in the slide facing tools, rough and finish cutters, are provided for each part to be faced, and the roughing cutters are completely off the surface before the finishers start cutting.

3.—This is a standard combination tool, carrying a bar, on which is clamped a standard boring head for the large bore. This bar is the same one as used in the first operation. The combination tool also carries a radius cutter for the edge of the rim, and a positive drive for the boring head is obtained by another turning tool holder in one of the empty holes, but is not shown in the drawing.

4.—This is another combination tool, which carries a finish boring head for the large hole. It is obvious that the combination tool is not necessary at this operation, and a standard boring bar holder could be used in its place. However, the combination tool is already in position on the turret after the first operation, and forms a useful means of carrying the boring bar.

5.—This is a finish facing cutter for the edge of the rim; it is carried in the front tool post, and operated simultaneously with 4.

The machining time for the two operations is 35 minutes.

CHAIN SHELLS

A RECENT British patent refers to a chain shell, illustration and description of which follows. It consists in the employment of a chain or chains wound around the gaine and separated by discs or cylinders which will keep the chains in place until the projectile case is emptied. A simple form of the invention is that in which the projectile is loaded with short lengths of chain which are laid therein in coils, but which will, after explosion, become stretched and, in addition to having a high forward speed, will rotate, and thus assist in increasing the ripping effect. These lengths of chain may have weights attached to their ends, and are preferably laid in short spirally-wound coils, separated to prevent the chain becoming entangled, and increase its velocity. Figs. 1 and 2 show sections of two forms of projectile constructed in accordance with this invention. In Fig. 1 a series of two discs D joined together by short tubes adapted to drop over the gaine and constructed to receive the chains E are used. In Fig. 2 the space C is divided by two

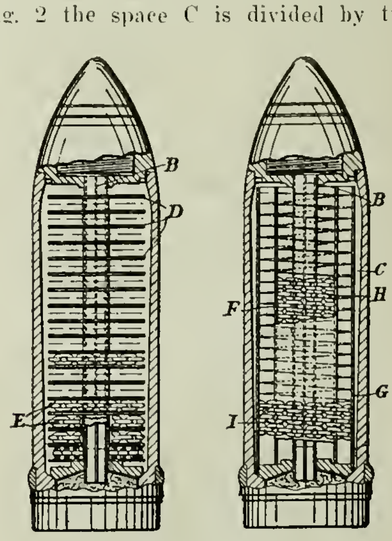

FIG. 1. FIG. 2.
CHAIN SHELLS

cylinders F and G of press-pan or other suitable material and a coil chain H is laid in spiral fashion around the gaine B and inside the cylinder F, whilst the second chain I is similarly laid around the outside of the cylinder H and inside the cylinder I.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

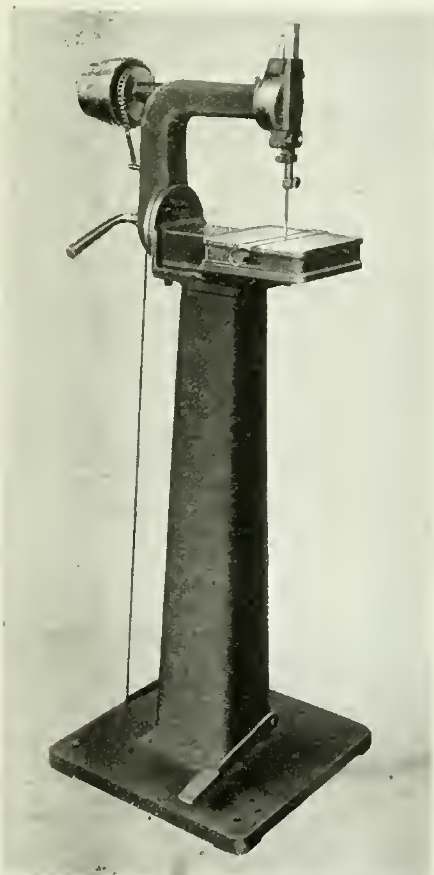
COLUMN FILING MACHINE

A FILING machine embodying novel yet well-tried principles of design is illustrated herewith, being of the column type supported directly from the ground. It is built with a solid type table and all of the adjustments necessary are made in parts above the table.

A three speed cone pulley belt drive is provided on the end of the main shaft which in turn operates the vertical ram by connecting rod, the stroke being adjustable from 1½ in., to 2½ in. and the chuck being adjustable to take standard straight files without any additional work of babbitting etc.

An adjustable hardened roller bearing takes the side pressure of file, and is adjusted by a knurled screw so as to allow the angle of the file to alter when the head is swiveled to the desired degree indicated on the scale shown. A pedal operated clutch on the main shaft controls the starting and stopping.

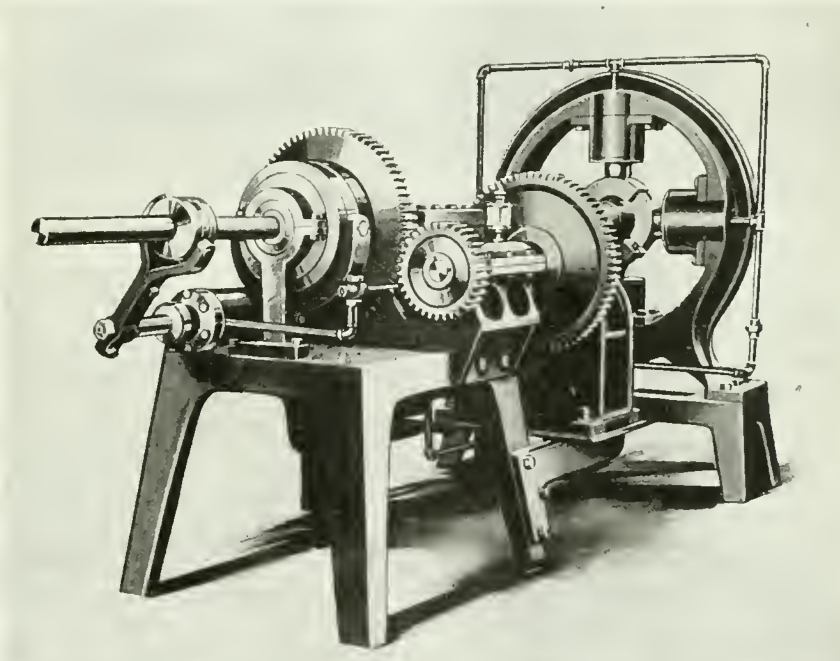
All bearings are of phosphor bronze, and all working parts are above the file eliminating trouble and wear due to particles of metal getting between them. The Noble and Westbrook Mfg. Co., Hartford, Conn., are the makers of this machine.



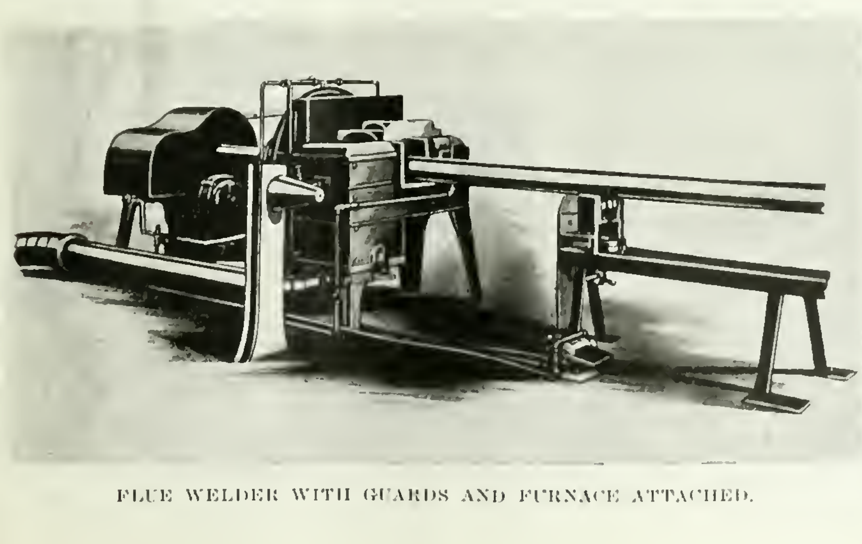
FILING MACHINE WITH OVERHUNG SWIVELING HEAD AND ADJUSTABLE FILE SUPPORT.

UNIVERSAL FLUE WELDER

A UNIVERSAL flue welder is shown in the accompanying illustrations, which has been developed by the Southwark Foundry & Machine Co., Philadelphia, to meet conditions that have arisen since the general adoption of the locomotive superheater. While built sufficiently heavy to perform the welding of large flues, the machine takes safe ends of greater lengths than the limits of previous types of welders.



REAR VIEW OF FLUE WELDER SHOWING END OF MANDREL EXPANDING SHAFT.



FLUE WELDER WITH GUARDS AND FURNACE ATTACHED.

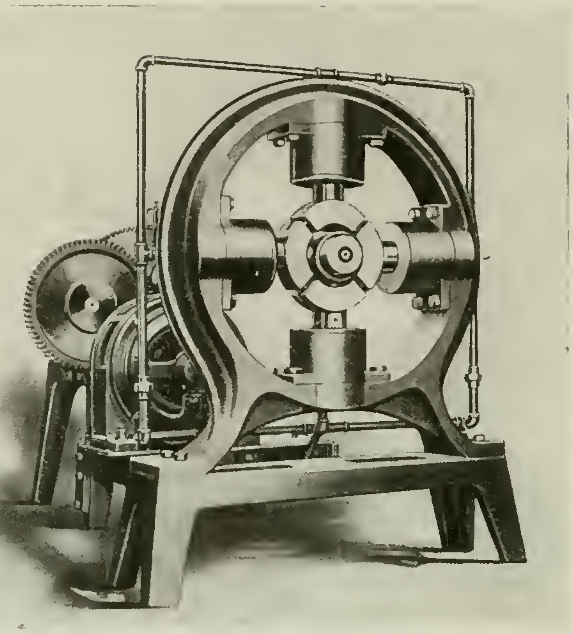
A special device on the welder enables the weld to be worked on the inside instead of on the outside, thereby avoiding trouble arising from outside welding which works the metal down to a solid mandrel, the consequent reduction of area being detrimental from the viewpoint of free passage of gases, as well as preventing the entrance of superheated elements.

The machine consists of two main parts, the clamping head at the front, and the driving mechanism at the back. The clamping head is made from one circular-shape casting, four air cylinders mounted on the inside. The pistons are fitted with metal snap rings, instead of the ordinary cup leather type. The front end of the piston rods are equipped with sectional dies, which clamp the outside of the flue at the line of weld.

the cylinders operating simultaneously with the opening of the valve.

Running through the centre of this head longitudinally with the machine is the welding mandrel which fits the inside of the flue. Four rollers are assembled in the body of this mandrel, which is hollow. Tapered and free in their bearings, they can be moved radically by inserting a taper mandrel that reaches through the middle of the spindle from the back of the machine. This mandrel is operated by an air cylinder also controlled by the main foot valve. The main mandrel is driven through two gear reductions to a $1\frac{1}{2}$ h.p. motor.

A cast iron tank or water back protects the welding head from excessive heat from the furnace. The size of the mandrel, back of the welding rollers, approximates the inside diameter of the flue. This supports the weight of the safe end while being heated and moved to the welding position, which prevents any loss due to the dropping off of safe ends, as frequently occurs.



FRONT VIEW OF FLUE WELDER SHOWING CYLINDERS, DIES AND MOTOR.

Standing away from the furnace, the operator uses a foot valve which controls the entire operation of the welder. The piping is so arranged that the clamping heads close in on the outside diameter of the flue before the taper mandrel expands the rollers to make the weld. Driven directly from the motor, the mandrel is started by an air chuck operating automatically with the clamping of the flue.

It is customary to rig up the front of the machine with some type of roller table to support the long flue, and with this complete equipment, one crew easily can weld in a day of ten hours 120 superheater flues.

The machine has a capacity up to $5\frac{1}{2}$ in. flues, uses air pressure of 80-100 lbs. per sq. in., and is driven by a $1\frac{1}{2}$ horsepower motor. The air pistons are 7 in. dia., speed of mandrel 100 revs. per min., and floor space occupied 3 ft. 6 in. x 9 ft.

AKIMOFF DYNAMIC BALANCING MACHINE

A PERFECT dynamic (running) balance is something very hard to obtain. On other hand, it is often to be desired, particularly in high speed machines. The importance of running balance in high speed machinery is well understood. Rotating machinery cannot run properly unless it is perfectly balanced. Even a small amount of unbalancing will give rise to a host of troubles, such as, noise, vibration, excessive power consumption and undue wear of the bearings. These effects are especially serious in high speed machinery, as for instance, automobile crankshafts, motor armatures, and turbine runners.

As a means for determining the amount of unbalance obtaining and correcting it, Mr. N. W. Akimoff, chief engineer of the Dynamic Balancing Machine Company of Philadelphia, Pa., has perfected this machine. The machine is driven by a Westinghouse motor and the picture shows it ready for balancing a motor armature. The balancing of rotating elements of electrical machinery and of automobile shafts have, so far, been two of the most successful applications for which this machine has been used. The principle upon which the machine operates may be described as follows:

An unbalanced condition of a body rotating at a relatively high speed may be due to lack of static balance or lack of dynamic balance. An indication of static unbalance may be obtained with a static balancing machine. Correcting for such unbalance involves drilling one hole or adding one weight to bring the centre of the mass of the body on the axis of rotation. In a statically balanced body, however, two masses on opposite sides of the axis of rotation, located axially at a distance from each other, form on rotation, a couple which develops vibrations, as is noted in defective commutators in electrical machinery, etc. The Akimoff dynamic balancing machine furnishes a means for determining easily and correctly the magnitude and plane of the couple, by the establishment of another couple, which, maintaining the static balance, counteracts the couple which produces dynamic unbalance. The magnitude and plane of this couple indicates the correction to be applied to the body under test to produce a perfect dynamic balance.

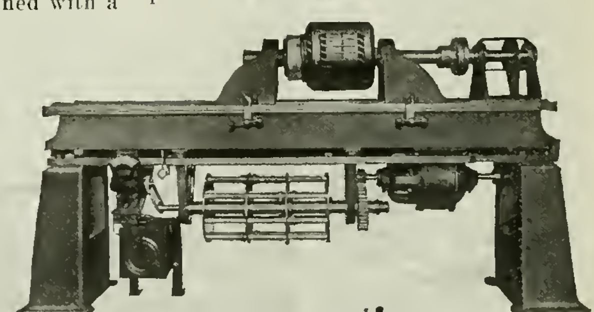
A rigid horizontal beam, such as a lathe bed is hinged at one end of the machine and supported by a spring at the other. The body to be tested, already in perfect static balance, is rotatively supported on the beam. If dynamically unbalanced, the body will, on rotation, cause the beam to vibrate in a vertical plane. The object of the spring is to amplify the vibration. A so-called squirrel cage is located on the underside of the beam and, in operation, is rotated in unison with the body being tested. This squirrel cage consists of two circular discs carrying an even number of rods arranged slidably in the two discs and parallel to the axis of rotation of the cages. When the ends of the rods are in one plane, the cage is in both static and dynamic balances, but if two opposite rods are displaced the dynamic balance is destroyed and the couple produced will itself cause vibration of the beam. One pair of rods in the squirrel cage would suffice if the relative position of the rods could be altered through the transmission device, but for convenience, three or four pairs are employed and even then it is sometimes necessary to change the angular position of the cage so that the balancing can be done by one pair of rods and not two.

In making the test of a body the cage is adjusted so that the vibration produced in the beam by the body are damped out by those set up by the squirrel cage. An arrangement whereby the rods of the cage may be adjusted axially while the cage is in rotation is provided and by utilizing this arrangement the rods are shifted until the desired effect is produced.

Peggy—"Daddy what did the Dead Sea die of?"

Daddy—"Oh, I don't know, dear."

Peggy—"Daddy, where do the Zeppelins start from?"



DYNAMIC BALANCING MACHINE.

Daddy—"I don't know, dear."

Peggy—"Daddy, when will the war end?"

Daddy—"I don't know."

IMPAIRED STEEL PRODUCTION

ASIDE from the war news of the past week, steel, whether relative to its commercial importance or stock market standing, continues to play fast and loose with both reason and calculation. Germany's note of "frightfulness" has naturally had some effect on a situation already sufficiently acute; at the same time, we may not lose sight of the fact of its being but an incident in a day's happenings. The output of steel, both for munitions and commercial requirements, tends toward further restriction, and indications are that still lower records are in sight in the immediate future. Coke, a front rank essential in the production of steel, is both high in price and scarce, the two being interdependent. The scarcity is, however, largely due to congested transportation facilities, which appear to be growing steadily, although perhaps imperceptibly worse. What is true of the steel situation as a whole on the North American continent is equally so of that more specifically Canadian, although such concerns as the Steel Company of Canada and Algoma Steel Corporation are perhaps most directly affected in the matter of fuel for metallurgical purposes. It should, of course, be borne in mind that no small contributory to the railroad congestion prevailing is the circumstance of our being meantime in the grip of mid-winter storms and frosts, each of which contributes its quota to the magnification of other disabilities incidental to an altogether abnormal time.

Steel for shells may be said to still constitute by far the major portion, if not practically the total output of more than one of our four big steel plants. It is understood, however, that neither of them are producing the scheduled quantity, largely because of the highly abnormal transportation situation which has been allowed to develop and become a menace to our metal-working industries generally, whether munitions-engaged or otherwise. We are, of course, importing steel from the United States, but, even from that source, transportation troubles militate against even moderately prompt receipts. Our finishing plants, as a result, are in many cases operating below their rated capacity.

As an example of the extreme acuteness of the steel situation, particularly as regards munitions requirements, it may be stated that considerable credence was placed in an early-week report of action taken by the Imperial Munitions Board relative to modification of the urgency of the steel requirements—shapes, for the $90,000,000 one-time known "mystery block" at corner of Yonge and College Streets, Toronto. The action taken was imaginary, just as is the "mystery" regarding the concern about to erect the "block" or departmental store. This latter, we might state, will be both costly and pretentious when wholly complete as planned, involving as it does a capital outlay of $90,000,000, covering an area bounded north and south by College and Hayter Sts., and east and west by Yonge and Terauley Streets, and rising to a height of 15 storeys. One unit only of 9 storeys, constituting about one-sixth of the structure at that height, and involving an expenditure of $10,000,000, is meantime to be erected, and for this the steel is on order. Actual construction is not being pushed, however, a circumstance amply borne out, when it is known that delivery of steel (Bethelehem) is entirely at mill convenience: that rolling is not expected to begin until July of this year, and erection under the most favorable general conditions until July, 1918.

Steel is, nevertheless, scarce, and as an instance of how imperative are the requirements for munitions, it may be stated that two Canadian corporations specializing in both heavy, medium and light forgings, in addition to other products, finished and semi-finished, have had to decline tenders for the supply of forgings incidental to the requirements of our marine engineering and shipbuilding plants. The forgings in question have had, as a result, to be imported from the United States.

The downward trend in market values of Canadian steel stocks may be reckoned as healthful, whether "Peace with Victory" for Britain and her Allies be imminent or otherwise. Profits on munitions production are comparatively lean, whatever the particular line or lines being manufactured, and we look to see the price recession reach rock-bottom foundation well in advance of a cessation of hostilities. Under such circumstances, and only so, will the peace time readjustment period be brief, and abnormal dislocation of industrial enterprise in Canada be avoided.

HELP TO WIN THE WAR

THOSE who cannot go to the Front can help in a most practical way by saving their money and placing it at the disposal of the Government to assist in financing the war. The new War Savings Certificates which have been created by the Government to encourage thrift and economy, and to give everyone an opportunity to assist in financing our war expenditure, are now on sale at every bank and money order post office in Canada. The $25 certificate sells for $21.50, the $50 for $43, and the $100 for $86. As an investment, these certificates offer many attractive features—chief of which are the absolute security and the excellent interest return. For every $21.50 lent to the Government now, $25 will be returned at the end of three years.

There are two other features which are especially interesting to small investors. First, the certificates may be surrendered at any time, if the buyer should need his money; and second, each certificate is registered at Ottawa in the buyer's name and, if lost or stolen, is, therefore, valueless to anyone else. Notwithstanding their excellence from an investment standpoint, the certificates should appeal strongly to our people, because they offer to those who must needs remain at home a splendid opportunity for a most important patriotic service. The person who honestly saves to the extent of his ability and places his savings at the disposal of the Government by purchasing these certificates, may feel that he is having a direct share in feeding, equipping, and munitioning our Canadian soldiers, who are so nobly doing their part on our behalf and that of world freedom.

The General Market Condition and Tendency

THE industrial situation has been materially affected by the breaking-off of diplomatic relations between the United States and Germany, and further developments are being awaited with interest. The effect, so far, has been most noticeable in the ingot metal markets, where prices have advanced on copper, tin and antimony. The advance in tin, however, is due more to the possibility of shipments being lost on account of the proposed submarine blockade and not because of the likelihood of an increase in demand, as in the case of copper and antimony. Steel prices continue on the up-grade, iron and steel bars, plates and shapes all having reached higher levels. The steel market is very strong, and the recent developments in the international situation will tend to further strengthen the situation. The output of the mills is still being curtailed on account of the difficulty in obtaining supplies of coke and raw material in sufficiently large quantities. In this regard the outlook in the meantime is not very bright, although a strenuous effort is being made to relieve the congestion of freight by the railways. Canadian foundry pig-iron continues off the market and a considerable tonnage is now being imported from the United States. The machine tool market is quiet, pending the placing of third and fourth quarter contracts for munitions.

Montreal, Feb. 5.—The rupture of diplomatic relations between the United States and Germany has had a disturbing effect upon the entire industrial situation. Early future conditions will be largely indicated by developments of the next few days. Freight congestion and embargoes are causing considerable inconvenience and many factories are seriously handicapped through non delivery of much-needed material.

Pig Iron

Railroad embargoes are seriously affecting the pig iron situation and poor delivery of raw materials makes it very difficult to maintain maximum production. The chief factor in the situation is the coke shortage, furnaces being forced to operate light or suffer temporary shut down.

Foundries are also handicapped for the same reason and prospects of early relief are not very encouraging. One local foundry paid as high as $20 per ton for sufficient coke to make a certain casting, being unable to secure delivery on several cars held up a few miles from Montreal.

Steel

A new condition is likely in the steel situation, following the developments of the past few days and those that will take place during the coming week. The market continues very strong and comparatively steady under the tension that prevails throughout all branches of industry. Nervousness is not pronounced but the trade is anxiously awaiting definite action on the part of the U.S. government in respect to the latest crisis in international relations. That the next week or two will mark an important period in the year's history is more than possible, but at the moment it would be premature to reflect upon early future conditions. The steel situation at present is seriously affected by the difficulties experienced in transportation of materials, railroad embargoes and weather conditions interfering with the satisfactory shipments of all classes of raw and finished material. While a declaration of war on the part of the United States would probably mean increased activity in the steel industry with a corresponding advance in cost of material, a relaxation of the contemplated submarine warfare would have little effect upon present conditions, owing to the abnormal activity that is promised for more than a year hence. With the exception of rolling billets and blue annealed sheets, both of which show advances, the market is unchanged and prices remain firm. Local dealers report the situation as firm as usual, but anticipate some interesting changes, should developments force the United States to take the steps which generally follow a diplomatic break.

Metals

The general market is again featured by activity in some of the metals, with the coming week promising still further developments, the extent of which is at present very uncertain. The metals are very strong with copper steady but unchanged. Tin shows a sharp advance owing to sea risks. Spelter is quiet following a short active period. Lead is stronger while antimony is shooting upwards. Aluminum is active and very firm.

Copper.—The market is still unsettled awaiting the outcome of present relations between the United States and Germany. The underlying tone of the situation is very indefinite, and unsettled conditions will likely prevail for some little time until conditions develop further. Copper is comparatively strong but the future is uncertain. Strength has been added to the London market, while New York reports little change. The local situation is steady with prices firm and unchanged.

Tin.—The sharp advance on London market has been followed by a further rise in New York the quotation being now 51½ cents. In view of the present outlook, and contingent risks on tin shipments, local dealers are now quoting 56 cents per pound on a fairly active market; this is an advance on the week of 8c per lb.

Spelter.—The recent strength shown in spelter attracted sellers to the extent of offering a larger volume of metal than the trade could absorb, with the result that the market reacted to a lower level. The New York market which last week advanced ¾c shows a decline of one cent the week, the current quotation being 9¾c per lb. Dealers here however are quoting 15c, an advance on the week of ½ cent per lb.

Lead. — The leading interests have placed their nominal quotation on a basis of 8c. This is ½ cent higher than last week, and the situation has taken on a serious aspect owing to the fact that consumer's supplies are low, and considerable doubt exists as to the whereabouts of metal in transit. The existing uncertainty of early future conditions does not tend to relieve the situation and further strength with increased prices is not improbable. The trust price is now 8c with independents asking 8½c. The local market is active and stronger, the dealers having advanced their quotations to 11c, this being ½ cent above last week.

Antimony.—The market is still featured by the active upward movement of antimony. This strength is largely due to the delays in shipments of metal, but U.S. war possibilities may be a factor in the remarkable return to high tide during the past few weeks. Following the advance of last week, New York announces a further advance of 4c, the nominal price now asked being 25c per lb. Canadian requirements are heavy and possible developments on the other side might curtail the early future supply so that further strength may be expected. The week's advance shows an addition of 7c, the present local price being 25 cents per pound.

Machine Tools and Supplies

Business in machine tools continues satisfactory but the volume is not heavy. Orders for single tools are still fairly active but builders are looking forward to additional activity when further shell contracts are placed. Firms making shells are fully occupied, and additions to plant capacity mean the constant placing of new machines. Several local firms are taking over buildings and increasing their output. One plant here is purchasing 35 special machines as an addition to their present equipment which will increase their output over 100 per cent.

Scrap

In common with other markets, old materials are affected by uncertain conditions. At present the situation is marked by nervousness; with the most recent tendency showing an upward movement in price quotations. New York prices are generally higher and local dealers are slightly in advance over last week on machine compositions, turnings and heavy lead.

Toronto, Ont., Feb. 8.—The severance of diplomatic relations between the United States and Germany affects Canada closely, but what the future holds for this country in this regard is difficult to determine. Developments will be watched, however, with intense interest, especially as they affect the steel trade, metal markets, and machine tool business, more particularly in regard to the munitions industry. The fact that the U. S. would be an ally would minimize any adverse effect produced by the situation. There has been some improvement made during the week in the freight situation, but the severe weather has hampered the railways in their efforts to relieve the congested conditions.

Steel

The latest development in the international situation will tend to strengthen the steel market. Whether the United States are actually drawn into the conflict or not, the preparedness policy advocated some time ago will likely be put in effect. This would entail a further demand for steel at a time when the mills have heavy commitments. As Canada is not at the present time entirely independent of the U. S. mills, the outlook here is somewhat uncertain, as there is a possibility of supplies of steel from the States being partially cut off. Such a contingency, whether remote or otherwise, should be considered, as the effect would be more or less serious in view of the enormous demand for steel for our munitions and the meantime inadequate output of our mills. In any event, continued upward movement in prices seems inevitable, and indications of this may be seen in a further advance in iron and steel bars, plates and small shapes, which are now quoted as follows:—Iron bars, 4c; steel bars, 4.25c; shapes, 4.75c; and plates, 5.85c per pound. Production is still running behind the tonnage anticipated, as deliveries of raw materials are slow on account of transportation difficulties, accentuated by the severe weather. Two fair-sized orders for structural steel have been placed recently. The Dominion Bridge Co. has been awarded 13,000 tons for the new departmental store—"Mystery Block," Toronto, Bethlehem shapes being specified, and the Imperial Munitions Board has placed an order for 2,500 tons of shapes with the Hamilton Bridge Works for the new steel plant at Ashbridge's Bay.

Prices of black sheets are very firm, and the demand in the primary markets continues very heavy, particularly for blue annealed material. The sheet mills are badly handicapped by the scarcity of raw material and fuel, and production is being curtailed. There have been no price changes on either black or galvanized sheets, but higher prices are expected any time. Canada plates, bright, have advanced to $7.50 per 100 lbs.

The situation in the steel trade in the States is one of watchful waiting, pending developments. Demand has just begun to improve following the set-back caused by peace talk; now new buying has been again suspended temporarily. Prices, however, show no indication of weakness and the upward movement in values is expected to continue. The only important advance to note is in forging billets, which are now $85 per ton.

Pig Iron

There is really no change in the pig iron situation. Canadian foundry iron is still off the market, and there is no prospect of supplies being obtainable until there is sufficient coke available for the furnaces to operate. Coke is still a very scarce commodity, notwithstanding efforts made by the railway companies to relieve the situation. A considerable tonnage of pig iron is being imported from the States.

Scrap

The market is very firm and prices generally have an upward tendency. Copper wire and No. 1 machine composition are both higher, while other copper scraps will undoubtedly advance. Lead and zinc have also advanced about 1c per pound. Although the embargo on steel turnings has been lifted, prices are higher, this material being now quoted at $9.

Machine Tools

The recent development in the States is being watched with interest in local machine tool circles. If the U. S. Government find it necessary to take over munition plants for their own requirements, some difficulty may be experienced in getting machine tools from the States into Canada. Apart from this, business is quiet except for a fair demand for single tools. Canadian machine tool builders continue very busy on munitions equipment, which is not confined to domestic trade, as some export business is being done also.

Supplies

Prices continue very firm on all lines of machine shop supplies, but comparatively few changes have been made during the week. Manila rope, however, has advanced 2½c, and is now quoted at 29½c, while transmission rope and drilling cables are quoted at 37½c and 32½c respectively. Grindstones have advanced 45c per 100 lbs.

Metals

The possibility of the United States taking an active part in the war has caused considerable excitement in the metal markets. The proposed German submarine blockade has also affected the markets, but this is a passing feature, as it is not very probable that shipments of metals will be seriously interfered with. Prices of some metals have already advanced, copper, tin, and antimony having all been affected. In all these cases, however, prices are entirely nominal.

Copper.—The market is excited on account of the war situation, but prices although higher, are nominal. There is practically no copper to be had for near-by delivery, as dealers who have metal are holding and awaiting developments. There is very little copper for delivery sooner than August to be had; this will have a tendency to keep the market firm. Copper has advanced 2c locally, and is now quoted nominally at 38c.

Tin.—The submarine blockade proposals have made the tin market nervous on account of the possibility of shipments of this metal being lost and available supplies diminished. The scare has sent prices forward sharply, but at the same time buying is restricted. Tin has advanced 10c locally, and is nominally quoted at 58c per pound.

Spelter.—Along with other metals, the spelter market is unsettled, but quotations are unchanged. Consumers are not in the market at all, while producers are adopting an attitude of waiting for further developments. Local price, 13½c per pound.

Lead.—The market has not been disturbed by recent developments, and the situation in lead is more favorable than in other metals. The "Trust" is now quoting 8c and "Independents" 8.25c to 8.75c New York. Local price unchanged at 10c per pound.

Antimony.—The market has been upset by the recent international developments and prices have advanced. Although antimony would not be affected by submarine operations, the outlook is unsettled. Antimony has advanced 6c locally, and is now quoted at 26c per pound.

Aluminum.—The market is firmer, but quotations are unchanged at 68c per pound.

Solders.—Prices have been affected by the advance in tin and continued high cost of lead. Current quotations are 6c higher, guaranteed being quoted at 35c and strictly at 33c per pound.

CANADA'S LAST FISCAL YEAR

THE public accounts for the last fiscal year were tabled in the House of Commons, Ottawa, on February 1, by the Minister of Finance. Total receipts on account of consolidated fund were $172,147,838, while the total expenditure for the ordinary expenses of administration amounted to $130,350,726. The surplus was, therefore, $41,797,112. Capital account expenditure totalled $38,566,950 on public works, including $7,078,000 on the National Transcontinental; $7,635,000 on the Intercolonial; $4,887,000 on the Hudson Bay Railway, and $4,909,000 on the Welland Ship Canal. The railway subsidies paid during the year totalled $1,400,000. The war expenditure was $166,197,755. The total expenditures under all headings were $209,350,000. The increase in net debt of the Dominion was $165,780,000, or practically the same as the amount set down for war expenditure.

Under the heading of war expenditure, the Militia and Defence Department was responsible for $160,433,000, the Justice Department for $1,287,000, the Naval Department for $3,274,000, and the Dominion Police for $201,000.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

Pay allowances and sustenance of the troops cost $100,788,000, transport $8,686,000, clothing $13,194,000, small arms and ammunition $7,766,000. The war expenses of the Justice Department include, of course, the cost of looking after the interned prisoners.

The consolidated fund expenditure for the fiscal year ended March last was a little over $5,000,000 less than the expenditure for 1915. The capital account expenditure decreased by nearly three millions. The details of receipts and expenditures show the huge transactions which the Canadian Government has put through for the Allied Governments in connection with war purchases for Canada. There was received from the Imperial Government during the twelve months $148,000,000, while there was expended on the Imperial Government account $186,000,000. From the French Government there was received $1,670,000, and expenditures on French account totalled $2,018,800. Russian and Italian Governments receipts and expenditures handled by the Canadian Government totalled about $1,000,000 each, while for the New Zealand Government, Canada spent nearly four million dollars.

One of the interesting items of the details of receipts is the acknowledgment of conscience money to a total of $371 by the Customs Department, $102 by the Finance Department, and $99 by the Marine Department.

CANADA'S NEW BORROWINGS

THE resolution of Sir Thomas White calling for legislation authorizing the Government to borrow $100,000,000 to meet maturing obligations of the Dominion, to carry on public works and to meet expenditures for general purposes, was adopted in the House of Commons, Ottawa, on February 1, and the bill based upon it was introduced. The Finance Minister during the discussion intimated that a considerable portion of any money which might be borrowed under the provisions of the bill would be obtained by domestic loans. He said he would like to float all loans in Canada, but pointed out that the condition of exchange might make it desirable to borrow in the United States.

He told the House that Canada's revenue for the present fiscal year would be sufficient to pay all ordinary and capital expenditures of the country and sixty or seventy million dollars of the principal of its war expenditure. He estimated that during the coming year it would be necessary to borrow $250,000,000 on this side of the Atlantic to meet war expenditures and additional sums to establish credits for Great Britain in the Dominion. Balancing the advances made by Canada to the Imperial Government to pay for munitions manufactured here, against the sums owing by Canada to the Imperial Government for supplies for the Dominion's troops overseas, he concluded that Great Britain was now indebted to Canada to the extent of $18,000,000.

ONTARIO LABOR BRANCH RETURNS

"WE are now getting the class of people we were after," says Dr. Riddell, superintendent of the Trades and Labor Branch Department of Public Works, Province of Ontario. "We make no attempt to handle the casual labor where work is obtained for a day or two. We are now in a position to handle skilled labor and we have got that class coming to the office. The Ottawa office shows probably the lowest cost per capita for placements of any place that I know of except one. There, for the month of January, it has been 46c. Wisconsin is down to 45c, and that's the lowest I know."

During January there were applications for work by 2,150 men and 1,430 women, while 700 employers sent in applications for help. There were placed 769 males and 121 females. These are the total figures for all the different bureaus in Ontario. The Bureau placed during the month the following:

Farm hands	3
Building trades	85
Clerical work	25

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—H. R. Poussette, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—Acting Trade Commissioner, Lonja del Commercio, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—G. B. Johnson, P. O. Box 109, Yokohoma. Cable address, Canadian.

HOLLAND—Acting Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrivskaya. Ploshch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 27-28 Pearl Building, East Paradise, Leeds. Cable address, Canadian. F. A. C. Bickerike, Canada Chambers, 36 Spring Gardens, Manchester. Cable address, Cantracom. J. T. Lithgow, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.

SPECIAL TRADE COMMISSIONER—LUMBER

H. R. McMillan, visiting Europe, Africa, Australasia and the Orient.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin, Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum Grubbeged No. 4, Christinnia, Norway. Cable address, Sontums.

CANADIAN HIGH COMMISSIONER'S OFFICE

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

Laborers	72
Munition workers	371
Metal workers, etc.	28
Miscellaneous	43

During January the applications for work from the different bureaus were: Toronto, 626 males, 935 females; Ottawa, 1,377 males and 16 females; Hamilton, 96 males, 489 females. Compared with December there were fewer applications last month and fewer placements in Toronto. The figures are:

	Dec. 1916.	Jan. 1717.
Applications	2,256	1,561
Placements	214	168

PULPWOOD SHORTAGE

A SERIOUS shortage of pulpwood in Canada during the coming year was predicted by J. A. Bothwell, of the Brompton Pulp and Paper Co., chairman of the Mechanical Pulp Section of the Canada Pulp and Paper Association, at their annual meeting in the Ritz Carlton at Montreal on January 31. The shortage will be of such extent, he continued, that the paper mills purchasing the entire wood supply are going to find themselves shut down for want of pulpwood by September 1, 1917.

That paper manufacturers had not raised prices to an unjust level, although they had made substantial profits last year, after many bad years, was the contention of C. Howard Smith, acting president. He called for standardization of lines, variety, shades and weights. Many lines were being imported that should be made in Canada.

RAILWAY MATERIAL PRICES

RAILWAY executives declare that the steady increase in the price of materials used in large quantities on the railways presents a serious problem.

Figures quoted by one of the officers of the Grand Trunk System show that many of the staple products used by the line have more than doubled in price during the last year. Brass has increased over two hundred per cent. in price, and the railway uses more than a million dollars' worth of this metal each year.

Copper has risen over one hundred per cent. in value, while steel bars, plates, angles, etc., hundred of tons of which go into railway maintenance each year, are costing three times as much as they did before the war and delivery is difficult to obtain.

Springs for engines and cars are other items which require to be constantly replaced, and these have increased in price about one hundred and eighty-five per cent.

A type of locomotive which two years ago could have been bought for twenty-seven thousand dollars cannot be ordered for future delivery at any figure under forty-five thousand dollars.

The Storey Pump & Equipment Co., Toronto, have been awarded a contract for a gasoline engine and pump by the town of St. Mary's, Ont.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

St. John, N.B.—The Nashwaak Pulp & Paper Co. will extend their mill.

Fergus, Ont.—Beatty Bros. are buying power house and foundry equipment.

Winnipeg, Man.—The Board of the General Hospital is considering building a power plant.

Montreal, Que.—Fire recently gutted the machine shop of J. K. McDonald, 318 West Craig street.

Edmundston, N.B.—Fraser's, Ltd., have selected a site here for its proposed pulp and paper mill.

Toronto, Ont.—The Imperial Munitions Board will build a forging plant and a machine shop in connection with the steel plant at Ashbridge's Bay.

Toronto, Ont.—Canadian Aeroplanes, Ltd., will shortly commence construction of a factory on Dufferin street. Jackson, Lewis Co., Toronto, are the contractors.

Toronto, Ont.—It is announced that a new aviation school will be established at Camp Borden at an estimated cost of $3,000,000. The plans include an aerodrome, hangers and machine shop.

Chatham, Ont.—Negotiations have been completed between the Chatham Bridge Co. and the Pittsburg Steel Co., whereby the plant of the former company will be taken over and operated by the Pittsburg concern.

Toronto, Ont.—British Forgings, Ltd., have taken out a permit to put in foundations for an electric plant at the foot of Cherry Street, near the Harbor Commission's ground area at a cost of $25,000, for the Imperial Munitions Board.

Winnipeg, Man.—The Greater Winnipeg Water District has ordered Thomas Kelly & Sons to add a considerable quantity of machinery, plant and equipment to that already in place upon their contract, so as to secure completion of the work within specified time.

Winnipeg, Man.—The Greater Winnipeg Water District Board has authorized the commissioners to call tenders for cast iron pipes, valves and specials for the pipe line between the Red River and McPhillipps Street reservoir. The estimated cost is about $250,000.

Halifax, N.S.—The coal mine at Port Hood, which has for some time been idle, is to be re-opened and operation will soon be on an extensive scale. The mine has good equipment for an output of two thousand tons per day. The Green Wood Coal Co., now operating at Thorburn, Picton County, has taken over the mine.

Vancouver, B.C.—John Coughlan & Sons have taken out a building permit for the erection of what practically comprises the first unit of the firm's new shipyards on False Creek. The permit which was issued by City Building Inspector R. A. McKenzie, provides for the erection of the machine shops and mould loft.

MUNICIPAL

Cayuga, Ont.—Extensions to the waterworks system are contemplated and will include pumps, cast iron pipe, water tank, etc.

Brantford, Ont.—Fire Chief Lewis has recommended the purchase of a motor tractor for an aerial truck and a new gasoline motor pump.

Chatham, Ont.—A by-law will be submitted to the ratepayers on February 20 for the erection of a pickle factory to cost $100,000, by Libby, McNeil & Libby, Chicago, Ill.

London, Ont.—It is reported that Hunt Bros., who operate a flour mill, may leave here and establish a factory at Fort William, Ont.

Ottawa, Ont.—Appropriations for public works for Toronto include $1,000,000 for harbor development, $120,000 for repairs to public buildings, and $500,000 for postal station A.

Oakville, Ont.—The Acme Rubber Co. by-law was carried by a substantial majority. It is understood that the purchase of the Ware factory will be completed very shortly.

Hamilton, Ont.—Fire Chief Ten Eyck has asked the City Council for an appropriation of $176,750 for the fire department. This sum includes cost of a motor aerial truck, combination motor hose and chemical wagon.

Peterborough, Ont.—The City Council have conferred with Sir Adam Beck regarding the acquiring by the city of the street railway at Peterborough, the gas plant, and the Otonabee electric distributing plant. These have been operated by the Hydro-Electric Commission for the past eight or nine months.

GENERAL

Elmira, Ont.—The Colonial Knitting Co. are considering the erection of a knitting mill.

Toronto, Ont.—The Dominion Envelope Co. will build a warehouse to cost about $50,000.

Niagara Falls, Ont.—The American Cyanamid Co. will rebuild their plant, which was recently destroyed by fire, at a loss of $200,000.

Galt, Ont.—No. 2 works of the Newland & Co. carding and spinning departments were practically wiped out by fire last Saturday. The loss covered by insurance will run into thousands of dollars.

Tillsonburg, Ont. — The Canadian Huntly Mfg., Co., which was recently incorporated has taken over the electric car works here. C. G. Hammond of Silver Creek, N.Y., is president of the company and W. H. Bennett of Tillsonburg is vice-president.

Toronto, Ont.—Permission has been asked from the Board of Health by J. B. Harris & Co. to erect a gelatine and glue factory on the Harbor Commission industrial sites, south-east of the Don. Mr. Harris, who was present at the meeting, said his company had taken five acres of land, and about half of this would be used.

Danville, Que.—Damage to the extent of about $40,000 was done by fire here on Jan. 29. The factory and storerooms of the Danville Chair & Specialty Co. were completely destroyed, and other sufferers were the Danville Mfg. Co., G. McCracken Flour & Feed Warehouse. About $25,000 in insurance was carried.

TENDERS

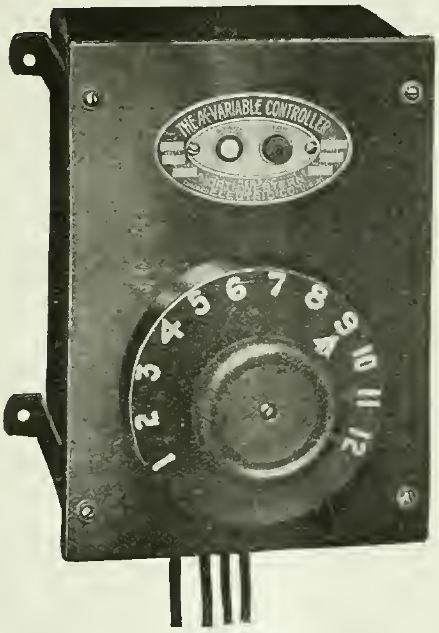
Winnipeg, Man.—Tenders will be called until February 12 for works required for the completion of the new Parliament Buildings, which include the following:—Heating and ventilating, electric conduit and wiring. Thos. H. Johnson, Minister of Public Works, Winnipeg.

Montreal, Que.—Tenders, addressed to the Board of Commissioners, City Hall, will be received until February 9, for the supply and delivery of auto sprinkler-flushers and auto-sweepers. Copies and specifications and forms of tenders may be obtained by the interested parties at the office of the superintendent of purchases and sales, where all necessary information will be given.

Ottawa, Ont.—Tenders will be received at this office until February 12. for the supply of: Brooms and brushes, chain, coal, hardware, hose, oils and greases, packing, paint and paint oils, Manila rope, wire rope and steam pipe, valves and fittings, for the requirements of the departmental dredging plant in Ontario and Quebec during the fiscal year 1917-18. These forms of tender can be obtained at the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Winnipeg, Man.—Tenders will be received at the office of the Winnipeg Public School Board up to February 8, for supplying the following material:—Blacksmith's coal, drawing, hardware, iron, steel, lumber, oils, varnishes, electrical, printing, required in connection with the Technical and Manual Training

Aikenhead's A.K.

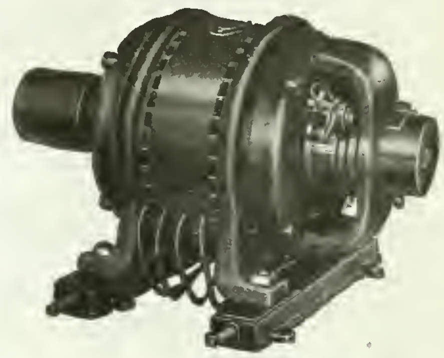


The A.K. Motors are built for high efficiency and long durability.

Single Phase, Variable Speed Type will run on 110 or 220 volt, 25 or 60 Cycle.

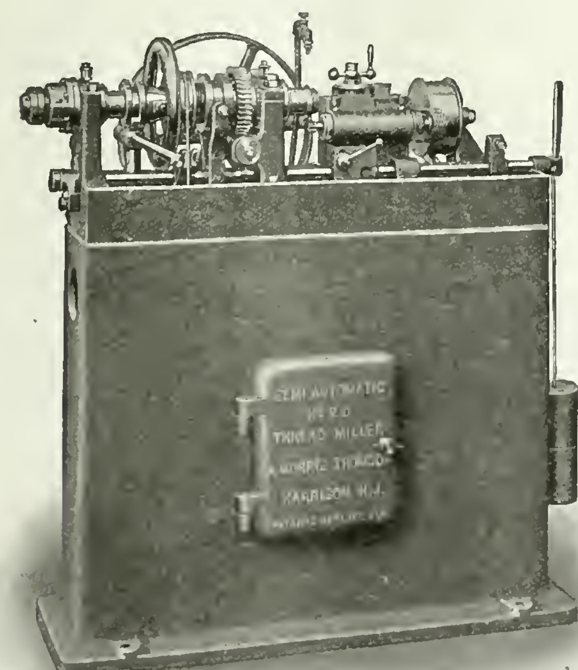
These come in sizes from ¼ H.P. up and are stocked, complete with a 12-speed Controller, in Toronto.

MOTOR AND CONTROLLER



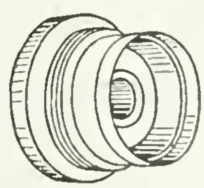
Aikenhead Hardware Limited, 17, 19, 21 Temperance St., Toronto, Can.

THREE A MINUTE!



ON THE

Morris-Thomson Semi-Automatic Thread Miller



14 Pitch Whit.
1·200 in. diam.
1-4 in. long on Bronze Primers.

Time-saving features:

Lever-operated collet chuck.
Lever-operated advance of cutter into work.
Automatic start and stop of work rotation.
Automatic withdrawal of cutter on completion of thread.
No screw adjustment to be made for each piece.
Operator has absolutely no thinking to do—levers to pull—that is all.
For full particulars of this and our larger machines with a capacity up to 12 inches diameter by 48 inches long get our new catalog.

T. C. M. Manufacturing Company, Harrison, N.J., U.S.A.

Schools of the city. For specifications, forms of tender, and further information required, apply direct to the Commissioner of Supplies, School Board Offices. R. H. Smith, secretary-treasurer, W. P. S. B.

Toronto, Ont.—Tenders will be received up to Feb. 12, for the supply of the following materials for the Township of York:—24 in., 12 in., and smaller sizes, cast iron pipe; 24 in., 12 in., and smaller sizes of special castings; 6 in., 12 in., and 24 in. valves; air valves, hydrants, tops, covers and plugs, venturi meters and recorders; 6 in., 12 in., and 24 in. check valves. Plans and specifications may be obtained from Frank Barber, township engineer, 57 Adelaide Street West, Toronto.

Ottawa, Ont.—Tenders will be received until February 15 for the purchase of old laundry machinery, the property of the Department of Public Works, and now stored in the old Baker Laundry, Wellington Street, Ottawa. List of machinery may be obtained on application to the clerk of works, Postal Station "F," Toronto; to the overseer, Central Post Office, Montreal; and to the superintendent Dominion Buildings, Ottawa. Inspection of the machinery may be made in the premises on application to the superintendent of Dominion Buildings.

CONTRACTS

The Otis Fensom Elevator Co. have been awarded the elevator contract for the chemical factory being erected by F. W. Horner, Ltd., Montreal, to cost $48,000.

Toronto, Ont.—The Hamilton Bridge Works, Hamilton, Ont., have been awarded the contract for the steel work for the steel plant which the Imperial munitions Board will build on Ashbridge's Bay. The contract calls for 2,500 tons of steel.

Winnipeg, Man.—The Greater Winnipeg Water District Board has instructed Engineer Chace to prepare alternative estimates on steam and electric railways from Deacon to St. Boniface, and also the cost of building and equipping proposed line in Transcona, including cars.

INCORPORATIONS

The International Nickel Co., have been licensed to carry on business in the Province of Ontario with a capital not to exceed $5,000,000.

W. G. Edge Ltd., has been incorporated at Ottawa with a capital of $900,000 to carry on business as iron founders machinists, etc., at Ottawa, Ont. The incorporators are William G. Edge, John Smith and James A. Cunningham all of Ottawa.

The Porcupine Pulp & Lumber Co., has been incorporated at Toronto with a capital of $10,000 to manufacture pulp and paper. The head office is at Toronto and the incorporators are R. H. Parmenter, A. J. Thomson and W. P. Morlock all of Toronto

Union Special Machine Co. of Canada, Ltd., has been incorporated at Ottawa with a capital of $25,000 to manufacture machinery of all kinds. The head office is at Toronto and the incorporators are James S. Lovell, Charles D. Magee and William Bain all of Toronto.

The Carter Welding Co., has been incorporated at Toronto with a capital of $40,000 to manufacture cutting and welding apparatus of all kinds at Toronto. The provisional directors are Herbert, W. Carter, Peter MacGregor Sorley and Frank S. Mearns all of Toronto.

MARINE

Ottawa, Ont.—The Government is advancing $1,500,000 to the Quebec Harbor Commission to enable it to go ahead with the system of harbor improvements now in progress there.

Ottawa, Ont.—The supplementary estimates brought down in the House provide for the sum of $96,000 for the improvements at Port Stanley and for $36,000 for similar work at Port Burwell.

Ottawa, Ont.—Special harbor and river votes include one million dollars for Victoria harbor, B.C.; $750,000 for Port Arthur and Fort William harbors, and one million each for Toronto, St. John and Quebec harbors. The Quebec vote is for the construction of a dry dock.

N.S. Schooner Launched.—The four-masted schooner Letitia Mackay was recently launched at Meteghan. It is the largest vessel of the year to be built in Nova Scotia. She is of 630 tons register. The vessel was built for Adam B. Mackay, of Hamilton, the contract for her building having been taken by Dr. T. H. MacDonald, of Meteghan.

Victoria, B.C.—The City Council have passed a resolution that the Dominion Government be asked to arrange for trackage accommodation, car-ferry slips and warehouse accommodation on the new breakwater and piers at the Outer Docks, so as to equip the port with facilities to handle all the freight that might be offering at Victoria.

Vancouver, B.C.—Work will be commenced shortly on the construction of a big addition to the Great Northern Railway Co.'s dock at the foot of Campbell Avenue, the extension to cost in the neighborhood of $50,000. E. B. Ford, chief engineer of the Great Northern at Vancouver, announces that the work will be started as soon as permission to carry it out is obtained from Ottawa.

Panama Canal Passage.—The average time taken by a vessel to pass through the Panama Canal is 11 hours 40 minutes, according to the *Panama Canal Record*. The minimum time recorded is 7 hours 17 minutes, and the maximum is 1 day 8 hours and 10 minutes. The figures, obtained by observing 158 vessels passing through the canal, show that more than half of the ships were in the passage between 9 and 12 hours. Those requiring more than 12 hours numbered 48.

Vancouver, B.C.—Active work on the construction of the proposed extension to the C. P. R. Co.'s Pier "D," at the foot of Granville Street, will likely commence in about a month, according to a statement given out by F. W. Peters, general superintendent at Vancouver. The pier will be made about 680 feet longer than it is now. The estimated cost of construction is in the neighborhood of $750,000. Work has already commenced on the preparation of the piles. They are being creosoted in North Vancouver.

Victoria, B.C.—C. C. Worsfold, Dominion Government district engineer, New Westminster, after an inspection of the Ogden Point breakwater has officially taken the structure over on behalf of the Government, and it only remains now for the contractors to erect the lighthouse at the outer end of the big 2,500 foot wall. It is understood that the contract for the 25-foot concrete tower which will house the big beacon will be signed up in the course of a few days, after which work will be started immediately.

Victoria, B.C.—The Board of Trade and the Esquimalt Graving Dock Committee have both been working for some time past to induce the Dominion Government to accede to their proposal to have a dock built here, and the matter is at present under consideration at Ottawa. It has been strongly urged that it would be a great advantage and saving to have the work done by Sir John Jackson, Ltd., as it has its plant already on the ground and that concern's ability to handle the work at a minimum of cost is recognized by all.

Vancouver Harbor Expropriation. — The arbiters appointed in connection with the proceedings taken by the Vancouver harbor board to expropriate the Kitsilano Indian Reserve have handed down their award, naming $666,200 as the amount of compensation which should be paid by the Harbor Commissioners for the property. The Harbor Board had offered $500,000 for the Reserve, the Dominion Government set a value of $1,250,000 upon it upon the advice of their valuator, and some of the realty experts called to testify gave it as their opinion that in a competitive market with large corporations seeking it, the sum of $2,000,000 might be secured. The reserve comprises seventy acres within the city limits.

Excess Profits Handed Over.—In reckoning excess profits which the shipping companies will have to hand over to the Imperial Government, *Fair Play* takes the amount set aside by thirty companies—namely, 23 pounds 4 shillings per ton gross—and gives a total of sixty-four millions sterling as the contribution from twenty million tons of steam shipping, British owned. "This would indicate," says the paper, "that the total profits of shipping companies exceeded the datum line by about ninety-one and a half million sterling, equal to

a dividend of nearly fifty per cent. on the pre-war value of two hundred million pounds. Shipowners, however, retain only about seventeen and a half million of this profit, out of which they have to set aside sufficient to cover the extra cost of building and repairs, which is now at a hugely inflated level."

Capt. W. T. Turner was in charge of the transport Ivernia when she was torpedoed on New Year's Day in the Mediterranean by a German submarine and sunk with a loss of 120 officers and soldiers and 33 of her own crew. He, it was reported, remained on the bridge until all the troops and his own crew had got away in the lifeboats and rafts before striking out to swim as the vessel went down under his feet. The majority of the crew lost were firemen who were killed when the torpedo exploded inside the Ivernia close to the stokehold. Captain Turner had only just joined the Ivernia, having left the Ausonia in London at short notice and traveled overland from Havre to Marseilles, where the transport was taking on troops and stores. He told the officers on the Ivernia how lucky he had been on the eastward voyage of the Ausonia from Montreal to London in escaping being torpedoed by a German submarine five miles off Ushant by an hour and a half. He steamed through the wreckage of an 8,000-ton French freighter, which was only six miles ahead of him, he said. Captain Turner is an expert swimmer, and was over three hours in the water when the Lusitania was sunk off the southwest coast of Ireland on the afternoon of May 1, 1915.

PERSONAL

W. W. Near, president of the Page-Hersey Iron, Tube & Lead Co., has been appointed a director of the Dominion Bank.

A. L. Smith, C. P. R. superintendent at London, Ont., has been appointed president and general manager of the Algoma and Eastern Railway, with headquarters at Sudbury, Ont.

B. G. Michel, recently engineer for Carleton Place, Ont., has opened offices in the Bank of Toronto Building, Kitchener, Ont., for consulting practice in civil and sanitary engineering.

G. J. Bury, vice-president of the C. P. R., will visit Russia for the purpose of acquiring such geographical and other information as might be of service in dealing with transportation problems. The C. P. R. is handling large quantities of freight via Vancouver and Vladivostok.

TRADE GOSSIP

J. Hall & Sons, Brantford, Ont., recently shipped a cutting-off machine to Russia.

P.W. Ellis Co., Toronto has had its charter extended to cover the manufacture of munitions.

Ottawa, Ont.—Charles H. Vessot, 67 Balsam Avenue, will construct a machine shop. Estimated cost, $6,000.

Sherbrooke, Que.—A factory for the manufacture of metals will be constructed by N. B. Pritchard, 40 Quebec Street. Estimated cost, $8,000.

Vancouver, B.C.—Plans are being prepared by the Amalgamated Engineering and Drydock Co. for a shipbuilding plant on Burrard Inlet. Estimated cost, $5,000,000.

Ottawa, Ont.—T. G. Brighan, 85 Duke Street, is in the market for asphalt-handling machinery, including shafting, sprocket wheels, pulleys, etc.

St. Johns, Que.—Work will soon be started on the construction of a plant for the Dominion Crucible Co. The company will also be in the market for machinery.

Hamilton, Ont.—The Tallman Brass Co. will shortly call tenders for an addition to their plant. Stewart & Wilton, 7 Hughson Street South, are the architects.

The Murphy Iron Works, Detroit, Mich., have been awarded a contract by the British Cordite Co. for the 400 h.p. smokeless furnace units to be installed at Nobel, Ont.

St. Catharines, Ont.—The Kinleith Paper Co. plans to build a brick and reinforced concrete addition. Denison & Stephenson, 18 King Street West, Toronto, architects.

G.T.R. Embargo on Freight.—The Grand Trunk Railway have placed an embargo on all cargoes at North Bay, whether carload or less. Traffic waybilled February 4 will be excepted.

Ford, Ont.—Plans are being prepared for a factory for the Canadian Lamp & Stamping Co., to cost $27,000. Tenders will be received by the architect, G. Jacques & Co., Boug Block, Winnipeg.

Toronto, Ont.—The Dominion Bridge Co., who have the contract for the new department store in Yonge street have placed an order for 13,000 tons of structural steel with the Bethlehem Steel Co.

Montreal, Que.—Canada Stove and Foundry Co. plans to build a concrete, brick and mill construction pipe foundry at St. Laurent. Estimated cost, $36,000. W. A. Mahoney, 78 Quebec Avenue, Guelph, Ont., architect.

Metals Coating Co., 90 St. James street, Montreal, have secured a new plant at 175 McCord street, into which they will move on May 1. They will manufacture their own apparatus and generally extend the scope of their business.

Ladysmith, B.C.—Construction work has been commenced on additions to the Tyee Smelter. Additional land adjoining the smelter property has been secured and approximately $100,000 will be spent on new buildings, among which will be a converter for the output of copper matte as well as blister copper.

Increase in Monthy Revenue.—A further increase in the Customs revenue is shown in the monthly statement issued on Jan. 31, by Hon. J. D. Reid. The January revenue was $12,936,314, an increase of $2,839,078. For the ten months of the fiscal year the revenue amounts to $119,549,396, an increase of $37,730,956.

Dundas, Ont.—Last Monday fire broke out in the Chapman Engine Works, and did damage estimated at $15,000. This is shared by the Chapman Engine Works and the Mercury Knitting Mills Co., which had its plant in the same building. The Chapman Engine Co. lost considerable of its plant and building.

Montreal Customs Receipts.—Customs receipts broke all January records for this port last month, with total receipts of $2,916,383. This was a considerable advance on the previous January record of last year, when the customs collections amounted to $2,265,525. For 1915 the January collections were $1,541,064, and for 1914 they were $1,669,455.

Lytle, Smith & Co., engineers' supplies, 422 St. James street, Montreal, has recently been reorganized and will hereafter be known as the Lytle Engineering Co., Ltd. With increased capital, the stock carried will be augmented and facilities provided for speedy delivery on power house and engineers' supplies. Additional space will be acquired by an early removal to 404 St. James street.

B.C. Metal Output.—Official figures of last year's output of British Columbia's mines shows a tremendous increase over all previous years. The returns from all sources are valued at $42,970,555. This is 45 per cent. better than the showing of the year 1915, and 32.50 per cent. greater than for 1912, which was the banner year previously. Following is a summary of the output of chief metals and coal products: Gold, $5,389,229; silver, $2,099,838; lead $3,186,773; copper, $18,429,934; zinc $3,648,599; coal, $7,093,352; coke $1,622,850; building materials, $1,500,000.

Montreal, Que.—The new paper mill of the St. Maurice Pulp and Paper Co. at Three Rivers, Que., has begun operations and the first run on one of the two fifty-ton units on Saturday last proved entirely successful. The capacity of the mill will be one hundred tons, and the second unit of fifty tons will be ready for operation in a few days. A sulphite mill, which has been built in connection with the news print mill has been in operation for several weeks. The St. Maurice Pulp and Paper Co. is a subsidiary of the Union Bag and Paper Co., an American concern.

Gets German Business.—As evidence that trade which was formerly enjoyed by Germany is being assimilated by Canadian firms, especially pertaining to the manufacture and export of articles of various articles of machinery, a Vancouver concern has just completed a large order for a building firm in Durban, South Africa. The Vancouver Engineering Works, of which Geo. Giles is the manager, is the firm which enjoys the distinction of securing this order, which is for a quantity of steel buckets to be shipped to the South African Cement Co. The contract is worth in the neighborhood of $5,000, and it is understood the firm secured the order in open competition.

Owen Sound, Ont.—Important additions will be made to the plant of the Northern Nut, Bolt & Screw Co., including the erection of a new boiler house, another wire annealing oven and a wire-cleaning house. The latter work will leave more room in the present building for wire machinery and frames. A new 50-h.p. motor will be installed to operate a nut-drawing plant. Four additional machines, an additional header and an additional bolt machine will be installed. A new hot galvanizing plant and an addition to the electrical galvanizing plant will be built. A keg and box mill will also be erected.

Vancoouver, B.C.—The establishment of new industries in Vancouver, and the locating of another in the near future, has been announced by Industrial Commissioner Davison. One of the new industries, the Maritime Motor Co., has the exclusive rights for the manufacture of the only type of gasoline driven mining and logging locomotive built in Canada. This locomotive can be built for any track. The first locomotive made in Vancouver will be shipped in a few days to a point up coast. Orders for five more locomotives have also been placed with the new firm. The Dominion Safe Works will establish in Vancouver in the near future, a site having been secured by it on the industrial island.

Record Freight Rates.—The highest freight rates in history have developed in the past few weeks, with the result that it now costs $75 to ship a ton of copper to Mediterranean ports, as compared with a $4 rate in effect prior to the outbreak of the European war. Current agitation concerning renewed submarine activity has likewise added its mite to an already heavily burdened situation, with war risks quoted as high as 10 per cent. to ports along the Mediterranean. To French ports the steamship companies have raised their freight rates to $45 a ton, against from $2.50 to $3 in normal times. To other ports bordering on or near the war zone rates have been advanced commensurately with those noted above.

WOODWORKING

Preston, Ont.—The Preston Car & Coach Co., will rebuild their plant which was recently damaged by fire.

Vancouver, B.C.—The saw mill at Skidegate, on Queen Charlotte Island, has been bought by the Weir Machinery Co. It has not been in operation for some time, but will be immediately opened up.

Sydney, N.S.—McCallum's carriage shop, a large wooden building on the corner of Townsend Street and the Esplanade, was destroyed by fire on January 21. The loss is estimated at $14,000, about half covered by insurance.

RAILWAYS—BRIDGES

Toronto, Ont.—An application will be made to the Parliament of Canada, at the present session thereof, for an Act to incorporate a railway company under the name of "The Kenora and English Railway Co."

Toronto, Ont.—An announcement was made recently by Sir William Mackenzie that the C.N.R. was about to commence the construction of a railway from Toronto to the Niagara frontier. The work will involve an aggregate expenditure of $7,000,000 and will result in a closer commercial compact between Toronto, Hamilton, St. Catharines and the United States.

BUILDINGS

Montreal, Que.—A new moving picture theatre is to be erected on St. Catherine Street West, opposite Phillips Square. The new theatre will be operated by the Holman Theatres, Ltd. The entire building will be fireproof, being constructed of concrete and steel, with a steel roof.

REFRIGERATION

Chatham, Ont.—The City Council has closed a deal with the Libby packing house of Chicago to open a branch here, the city giving land for a $100,000 plant.

CATALOGUES

The Atlas Crucible Steel Co., of Dunkirk, N.Y., manufacturers of fine tool steels, including L-XX high speed steel have issued a new catalogue of their various products. This catalogue deals comprehensively with the uses of the various steels and their heat treatments.

Firebrick Blocks.—A new bulletin dealing with the "Gates" firebrick blocks has been issued by John W. Gates, Montreal. The application of these firebrick blocks is shown by means of a number of illustrations accompanied by descriptive matter. The bulletin describes all types of blocks now being used largely in place of ordinary firebrick.

Steam Traps.—Bulletin No. 5 describes an interesting line of steam traps, made by the Geo. W. Cole Co., Toronto. The principal features of the "Cole" direct return trap are dealt with while the essential particulars and prices are given covering the various sizes. The bulletin is illustrated and includes a diagram showing a double trap installation with a table of fuel losses.

BOOK REVIEWS

The Story of the Canadian Pacific Railway by Keith Morris, 154 pages 7 in. x 4½ in., 10 illustrations. Published by William Stevens Ltd., London, England. This is a new book telling the story of the C.P.R. from the time of its inception to the present day. It is a tale of a great achievement beginning at a time practically 60 years ago, when the West was a trackless waste. The idea of building a transcontinental was first considered as far back as 1857 when an Imperial Commission was established by the British Government to enquire into the suitability of the then colony of Canada for settlement and the advisability of constructing a transcontinental railway through British Territory from the Atlantic to the Pacific Ocean. The opening chapter, "Pathfinders," deals with the physical condition of the country and the men who explored and surveyed the right of way, describing vividly the difficulties which had to be surmounted. The second chapter "Pathmakers" deals briefly, and in a popular style with the construction of the road, introducing George Stephens, Donald Smith, and other well known personages who were responsible for building the railway. The next chapter "Craigellachie" deals more particularly with the men of the time, who were associated in the great enterprise. The political and national advantages of connecting British Columbia with Eastern Canada, or, as it is calle,d "The Saving of British Columbia," are outlined in chapter four, while in chapter five "The Highway to Asia" the value of a transcontinental road is further emphasized. The next chapter, "Superstructure," reveals the economic advantages opened up by the C.P.R., while in the chapter "The Making of a Nation" the development of the country is described. The book concludes with an appendix on Canadian Pacific finance, and shows the wonderful progress which the C.P.R. has made, particularly during recent years. This is an exceedingly interesting book, relating in a popular style the development of that great enterprise which culminated in one of, if not, the most important transportation company in the world.

FOR SALE

MACHINE SHOP FOR SALE — MEDIUM size. Modern tools, lathes, Universal milling machine, Universal grinder. Equipped for good work. Box 267, Canadian Machinery. c10m

BOILER FOR SALE—HORIZONTAL RETURN tubular boiler, 66" diam., 15 feet long, 58 4" tubes. For immediate delivery. Steel Co. of Canada, Ltd., Montreal. (5)

GAP LATHE, 28 x 42 x 16 FT. BED, FOR sale, cheap; also emery wheel stand, power hack saw. Guarantee Motor Co., Hamilton, Ont. (tf)

FOR SALE — 1 NEW SHORE SCLEROscope, complete with all regular equipment. Pease Foundry Company, Limited, Brampton, Ont. Jct. 4341. c6m

FOR SALE — ONE WEST TIRE-SETTER, hydraulic shell banding machine, complete, for 3" Russian shrapnel shells. Consolidated Car-Heating Co., 413 No. Pearl St., Albany, N.Y. (6)

FOR SALE — NO. 50 GARDNER SWING grinder. Has 24" diameter ring wheel and was purchased for grinding base of 18-pdr. shells, but never used. Canadian Blower & Forge Co., Kitchener, Ont.

1—2-SPINDLE SHAPER, WOOD TOP, JOHN Ballantyne, Preston, make, used two months. 1 Dynamo, 45 lights, Toronto and Hamilton Electric Co. make. Used five months. Good as new. Box 195, Jordon, Ont. (R.T.F.)

25 CYCLE MOTORS IN STOCK TORONTO. Sizes in horse-power tens, fifteens, twenties, thirties, forties, fifties, seventy-five and one hundred fifty, standard voltage, slow speed. Boyd-McBurney, 220 King St. West. Main, 2330. c7m

SHRAPNEL SOCKET AND ADAPTER machinery, turret lathes, boring machines, cutting-off machines and thread millers tooled for operation. Globe Electric Machine Co., Hamilton. (tf)

FOR SALE — 1 NO. 3208 TATE-JONES furnace, also 1 nose annealing furnace, 14 holes, for 3" Russian shrapnel. Consolidated Car-Heating Co., 413 N. Pearl St., Albany, N.Y. (4)

FOR SALE—5' FULL UNIVERSAL RADIAL drill, with eight changes of speed. Scott Bros. make. Practically as good as new. Immediate shipment. Canadian Linderman, Ltd., Woodstock, Ont. (5)

2—30 H.P. PRACTICALLY NEW, LATEST type Canadian General Electric Company's 30 H.P., 60 cycle, 550 volt, 3 phase, 900 R.P.M. induction motors, with starting compensators and adjustable sliding base, pulley 14", diameter 8" face. Price $500 each f.o.b. Sarnia, Ont. 1—20 H.P., same as above, pulley 11" diameter, 10" face. Price $390 f.o.b. Sarnia, Ont. H. Mueller Mfg. Co., Sarnia, Ont. (3)

THE FOLLOWING SHELL MACHINERY is available for immediate shipment:
1—5" Jenckes Copper Band Lathe.
1—5" Jenckes Rough Wavy Groove Lathe.
1—6" Jenckes Finish Wavy Groove Lathe for Mark XVI. shell. Can be changed for Mark III. if desired.
1 Potter & Johnston Automatic Lathe.
1 4.5 Brown-Boggs Marking Machine.
Box 261 Canadian Machinery. (7)

WANTED

SHOP IN WINDSOR, ONT., EQUIPPED partially or wholly for special machine, tool and repair work. Send full details. F. G. Hubbard, Box 852, Bridgeport, Conn. c9m

WANTED — MOTORS 10 TO 50 HORSEpower, 25 cycle, 550 volts, alternating current. Quote price and delivery. Canadian Fairbanks-Morse Co., 1379 Bloor Street, Toronto. c11m

REPAIRING

ALL KINDS OF MACHINERY REPAIRED, rebuilt and installed. W. H. Sumbling Machinery Co., 7 St. Mary St., Toronto, Ont.

SITUATIONS WANTED

TOOL MAKER, ACCURATE, GOOD draughtsman, desires responsible position. Box 254, Canadian Machinery. (4)

SUPERINTENDENT, MECHANICAL, WITH proven ability, experienced in manufacture of small arm ammunition, 18-pr. shrapnel and high explosive shells, tool room and general machine shop practice; 20 years responsible position in Government arsenals, desires similar position; now disengaged. Box 262, Canadian Machinery, Toronto. (3)

SUPERINTENDENT OR WORKS MANager desires position with first-class concern. Specialist on automatic small die press work. Expert in handling men. Twenty years' experience as manager in cartridge factories. Capable of taking complete charge of installation. Apply Box 263, Canadian Machinery. (7)

SUPERINTENDENT WITH TWENTY-nine years' broad mechanical experience in different lines of manufacturing desires permanent connection with well known concern in need of a broad gauge man of unlimited energy and enthusiasm; long proven executive ability, strong personality, unquestioned integrity, strictly temperance, positive aggressive character with good judgment, highest references. Answer Box 260, Canadian Machinery. (2)

FOR SALE
Shipment from Stock

3—"Lees Bradner" Thread Millers arranged for milling 2" 14 thread in Nose of 4.5 Mark VII H.E. Shells.

For complete particulars—write

Williams & Wilson
Limited
320 St. James St., Montreal, P.Q.

SITUATIONS VACANT

DRAFTSMAN WANTED ON MACHINE shop equipment—jigs, tools, etc. State experience and salary expected. Box 265 Canadian Machinery. (9)

CANADIAN REPRESENTATIVE FOR American firms building special machinery, tools and gauges. Liberal commission to a business-getter. Box 266, Canadian Machinery. c9m

GENERAL FOREMAN AND CHARGE hands for machining operations on 18-pounder high explosive shells. None but experienced men need apply. P.O. Box 1164, Winnipeg, Man. (5)

WANTED — DRAFTSMAN CAPABLE OF designing small tools, jigs, etc. Steady employment. Please state experience and wage expected. Butterfield & Co., Inc., Rock Island, Que. (4)

WANTED SUPERINTENDENT CAPABLE of taking charge of 4.5 shell manufacturing plant. Must be thoroughly familiar with this type of shell and capable of producing results. Will pay good salary and bonus to the right man. State experience and full particulars in first letter. Apply Medicine Hat Pump & Brass Mfg. Co., Ltd., Medicine Hat, Alberta. c6m

SPECIAL MACHINERY

FUSE EQUIPMENT — SPECIAL MACHINery for manufacturing fuses, including rethreading machines for base plugs, with tools. "Harris," Box 1008, Bridgeport, Conn. c9m

FOR ALL KINDS OF GAUGES, JIGS AND special machines, also machine tools, lathes, milling machines, etc. Write H. P. Eilers, 580 St. Nicholas Ave., New York City. (5)

Wanted!

SECOND-hand Foundry equipment wanted for a foundry handling light castings. Complete equipment needed — must be in good condition.

BOX 264

SUBSCRIPTION PRICE—Canada, Great Britain, South Africa and the West Indies, $3.00 a year; United States, $3.50 a year; other countries, $4.00 a year; Single Copies, 15 cents. Invariably in advance.

INDEX TO ADVERTISERS

Canadian Government Small Arms Ammunition Factory

Contributed

Whatever ultimate effect the war may have on the preparedness of nations, the fact has been well recognized by this country that ammunition occupies a place of equal importance with men and guns, and evidence to this effect was given some time ago when the Government established the plant referred to, at a suitable inland point. Developments in methods and equipment have been frequent since August, 1914, and, together with the great number of operators on munition work, insure the future value of the new plant as a national asset.

THE small arms ammunition factory now in process of erection, is designed and will be equipped to manufacture 300,000 British .303 rifle cartridges in ten hours. It consists of a large number of separate buildings housing a wide variety of complicated manufacturing equipment.

Plant Layout

In the general plan of buildings layout, the routing of material has been carefully studied from a purely manufacturing standpoint to insure a minimum of handling. The type, plan, and general dimensions of buildings have been considered in their relation to the manufacturng equpmet. Several important details which influenced the designs were: The stresses set up by the power transmission; the determination of the amount and location of glazed window areas in order to provide the most desirable lighting and ventilating conditions with the maximum economy of lighting, heating, and ventilating; and the peculiar hazards involved in buildings where explosives are stored and handled. The manufacturing equipment has involved the purchase and installation of over 500 pieces of machinery, which are in the main of a highly special nature, complicated in design and varied in type and function.

The arsenal buildings are divided into four groups on a one-hundred-acre plot. Fourteen structures comprising the main manufacturing group are located in the north-west corner of the plot. These buildings, lying parallel to each other, are connected at their east ends by a passageway, which gives access to all. This group includes a two-storey brick office 40 x 90 ft.; brass foundry, 70 x 80 ft.; rolling mill, 70 x 200 ft.; case plant, 80 x 300 ft.; bullet plant, 60 x 300 ft.; machine shop and tool room, 42 x 300 ft.; case and bullet inspection building, 50 x 165 ft.; carpenter shop, 42 x 150 ft.; gas plant, 42 x 78 ft.; boiler house, 42 x 55 ft.; storehouse, 50 x 100 ft.; and a transformer station.

With the exception of the office, storehouse, case and bullet inspection building, all of the foregoing are of steel frame construction. The office building has hollow tile walls, with tapestry brick facing, wood floor joists and studding, and is plastered throughout. Here superintendent Lieut.-Col. S. S. Weatherbee, with his assistants, clerks, draftsmen, etc., have their offices. The chemical and mechanical laboratories, testing rooms, first aid ward, library and lecture room, also a two-storey fireproof vault, for books, records, and drawings, find a location in the office building. The storehouse, and the case and bullet inspection building are of one storey, with hollow tile walls, wood posts and roof framing and steel sash. The inspection building has a wood floor on a tar Rok base.

The main manufacturing buildings are one-storey steel frame, with hollow tile walls, steel sash, and concrete roofs. Only two designs have been used in the steel frames one a forty-foot truss, the other a fifty-foot truss on steel columns spaced nineteen feet on centres. The steel contract was awarded on a pound price basis, the steel work being then detailed so that material which Canadian yards had in stock could be used as far as possible. The use of trusses of the same design in several buildings simplified the detailing and shopwork, and resulted in remarkably quick shipment considering present market conditions. The boiler house and the rolling mill are floored with paving brick, with the exception of the space around the annealing furnaces in the latter, where cast iron plates set in concrete are used because of the handling of trucks of hot metal in these sections. In the gas plant and in all buildings where wet conditions of manufacturing are encountered, the floors are of concrete pitched to drains. All other floors are of hemlock underflooring, with maple wearing surface on a tar Rok base.

The steel sash used in the side walls are continuous between columns, and extend from the concrete sill at the top of the five-foot base wall to the eaves purlin. Monitor sash are also continuous between truss posts, and are about five feet high. All ventilating units in these sash are operated by a straight push operator in runs of approximately 150 feet between operating stations. All sash are glazed with factory ribbed glass, with ribbed wire glass in the vents. The roofing for all buildings is five-ply Barrett Specification.

CAR DEPARTMENT ACTIVITIES, C.P.R. ANGUS SHOPS, MONTREAL.

Loading and Magazine Group

The nine buildings of the loading group are about one thousand feet east of the main manufacturing buildings. They are all small, ranging in size from 16 x 26 feet, to 29 x 99 feet, and are connected by a passageway through which all materials may be handled unimpeded by weather conditions. They have tile walls, steel sash, mastic asphalt or special flashproof composition floors on a concrete base, and roofs of concrete or light wood framing. Toilet rooms and coat rooms are provided opening off the passageway, and are of similar construction to the other buildings, are separated from the main ground because of the dangerous operation carried on.

The eight buildings constituting the magazine group are situated about six hundred feet south of the loading buildings. They are of tile construction, with light wood roofs and non-gritty asphalt floors. Earth embankments eight feet in height surround each magazine building. This type of protection is also used around the loading buildings where quantities of explosives are in use or in storage.

Rifle Range

The fourth group includes a rifle range and an ordnance inspection and stores building, where final inspection is given the cartridges, and where they are packed and stored for shipment. The rifle range, housing both a 600-yard and a 60-yard range, is a concrete structure built below ground. The 600-yard range is a 6 x 7 foot reinforced concrete tunnel, curved to follow the trajectory of a bullet and having pockets at the side for target setting every hundred yards, and a target house at the east end. The 60-yard range is 2½ feet wide by 7 feet high, of similar construction to the 600-yard range, and having two side pockets and a target house. The firing house is a reinforced concrete structure about 25 feet square, the floor of which is seven feet below grade; the walls are thoroughly waterproofed with membrane waterproofing, and are lined inside with hollow tile. There are four rooms in the building—one firing room and a store room. Conduits are laid in the concrete walls of the range for telephones, instrument wiring, and electric lighting. Ventilation of the range is provided for by spacing louvres at intervals along each wall, while a suction fan is installed to dispose of the gases from the firing.

Ordnance Building

The ordnance inspection and stores building is of similar construction to the case and bullet inspection building, but is about 100 feet longer. The storehouse portion is separated from the inspection by a fire wall. Cartridge boxes are handled in this storehouse by an overhead telpher which also hoists them to the shipping platform. A system of asphalt roads and concrete walkways connects the various buildings and the several groups. The roof of the rifle range provides a runway for the electric trucks operating from the main manufacturing buildings group to the loading buildings. Two railroad sidings and a crossover give a length of 5,000 feet of siding at the plant, with a 100-ton track scale near the point at which the track enters the grounds, thus allowing the ready weighing of both incoming and outgoing materials.

Fabrication and Erection

In erecting the steel work for the plant the small size of the buildings and the uniformity of the trusses made assembly comparatively simple. The trussess were transported to the site completely fabricated and assembled, and they were erected by means of an ordinary wood derrick, working on temporary rails. Poling was resorted to in only a few instances. The details of the operation were so simple that no unusual or special methods were devised. For pouring the concrete roof slabs a large tower and chutes were employed, the tower being in the neighborhood of 225 feet high. Two towers were built, although it developed that only one was needed. This tower was used, in addition, to feed a screen beside it, which separated the sand from the gravel, the latter having been found to run rather high in sand. The one tower had sufficient radius of action to cover almost the entire plant, with the exception of some outlying or isolated jobs. The centering for the roof slabs was made in units in the shop, according to the plans of the roof layout, this being possible on account of the uniformity of truss and girder spacing. These forms were well oiled before use, and were employed over again from three to four times.

The excavation was, in the main, carried out by trenching machines. The foundations were plain walls, without spread footings, so that the side walls of the trench made forms for the concrete. The quality of the clay was such as to prevent any appreciable sloughing. The trenching machine was also used to excavate the range tunnel, the machine digging the core as well as the side trenches. It was the intention to use the earth walls as side forms for the concrete, and, although this was done in part, the rains caused washing, which necessitated separate form work.

Light, Heat and Power

The buildings are heated by direct radiation, making use of the Webster vacuum system. Wall radiation has been used throughout. A central boiler plant, consisting of four 150 horse power horizontal return tubular boilers, furnishes steam at 100 pounds pressure for heating and manufacturing purposes, this pressure being reduced at the several buildings to five pounds for heating purposes. Electric power is supplied by the Hydro-Electric Power Commission at 4,000 volts, 3-phase, 60-cycle, and is converted in the arsenal substation to 550 volts for power wiring and 220-110 volts for lighting. The lighting of all buildings has been carefully studied in relation to the machinery layout. In the loading building, extra precautions, including vapor-proof fixtures, have been employed to meet the dangerous conditions existing. Direct current is to be supplied for charging motor trucks, instrument batteries, and batteries for electrolytic work in the laboratory.

Ten toilet units have been installed, so located as to be most accessible. Automatic flushing water closets and stall urinals have been adopted, and the lavatories are the barrack room type, in enamelled iron. Fire protection is provided in the yards by means of three-way hose hydrants and hose-houses, with full equipment of hose, nozzles, wrenches, axes, and crowbars. Portable hose-reels, containing 1,000 feet of hose, are located near each group of buildings. Hose outlets are provided in the buildings, with reels containing 100 feet of 2½-in. linen hose. Small hand fire extinguishers are placed in all buildings.

CAR DEPARTMENT ACTIVITIES, C.P.R. ANGUS SHOPS, MONTREAL.

Production Equipment

The brass foundry will contain forty fires in one battery, ten of which are to be used for cupro-nickel and the remainder for brass. Square fires were adopted, as coke only is used in firing. A 5 ft. x 150 ft. steel stack, lined with fire brick to the top, provides ample draft. A direct motor-driven alligator shear is placed in the foundry to cut up copper pig and scrap metal. A convenient scale is provided to weigh out charges.

The gas plant is equipped with three anthracite producers, having a capacity of 115,000 cubic feet of gas per hour. Hot gas from two of the producers is used in the large annealing furnaces in the rolling mill without scrubbing, but the gas from the third producer is scrubbed, as this gas is used in the case-annealing and the tempering furnaces.

The rolling mill is equipped with one direct motor-driven alligator shear and one small trimming shear. A weighing scale is convenient for weighing trucks of metal for checking. There are two annealing furnaces or muffles, one single and one twin, and both are double-end. They are under-fired, using hot producer gas. The mills are made up of two stands, one breaking down and one finishing, direct-driven through herring-bone gears by a 250 horse-power motor. The usual immersing, pickling, and washing tanks are installed. In the rolling mill are also installed the first cupping presses for both cupro-nickel and brass.

The bullet plant houses all of the special bullet making machinery, same being arranged so that the flow of material is always progressing toward the inspection end. The lead extrusion press and equipment are also housed in this building. An aluminum extrusion press ordered from Quebec arsenal was made over into a lead extrusion press to make six reels of lead wire at one time.

The case plant contains all of the special machines with which to make complete brass cartridge cases. This machinery is likewise laid out for straight-line operation with minimum trucking.

The transmission equipment is of the latest type, employing a special hanger with turned plungers and using ball bearings. The shafting is turned and ground. The group drive system is employed.

The case washing plant equipment consists of fifty tumbling barrels for case washing, five special gas-fired annealing furnaces, and four case dyers, using indirect steam heat. Hot water and soap solutions are provided from the overhead tanks. Overhead mono-rail systems for handling cases to and from the annealing furnaces and into the immersion tanks are installed. All floors in this department are drained.

The tool room and machine shop are housed in one building, the tool room at one end and the machine shop at the other, with the tempering and grinding rooms between. Gas-fired tempering furnaces are installed. A small blacksmith shop and pipe shop is housed in a separate building. This shop is equipped with a motor-driven pipe machine to cut up 8-inch pipe, two down-draft forges, and a power hammer.

The carpenter shop for the manufacture of ammunition boxes, work boxes, etc., is equipped with the latest types of direct-driven woodworking tools. This shop has a capacity of 300 ammunition boxes per day. In connection is a complete tinsmith's equipment, with which to line the ammunition boxes with the usual waterproof lining of tin.

The loading and assembling plants require highly specialized equipment, and this is arranged for group drive. To avoid explosions due to sparks from either induced or static currents, thorough grounding has been provided. The drying of fulminate of mercury and potassium chlorate—always a dangerous operation—will be done at the Lindsay arsenal by means of vacuum driers which perform their work efficiently and quickly and reduce to a minimum the danger from explosion of these substances.

The elevating hand-truck system will be used in handling the bulk of the materials in each unit. Between the manufacturing and loading buildings, storage battery tractors will be employed, each capable of hauling several trailers, and of operating ten hours continuously without recharging. Both the electric tractors and elevating trucks are, we understand, recent developments by Canadian manufacturers.

Lightning Protection

Much study was devoted to the lightning protection of the magazines, loading, and fulminate buildings. High steel poles similar to flag poles are placed at the side of each building, extending down deep into the earth, to assure good ground connection. The lightning poles are about thirty feet higher than the building. To collect any leakage of lightning, short, stout lightning rods are placed on the highest point of each building. All metal in the building, including machines, shafting structural steel, etc., is connected in a loop or ring and thoroughly grounded, top and bottom.

Materials and machinery of Canadian manufacture have been in every case given preference, and only such products as could not be obtained in Canada were purchased in the United States.

Lieut.-Col. A. P. Deroche, R.C.E., Director of works and buildings, is in charge of the building work for the Militia Department, assisted by Mr. Clarence Noble, as supervising engineer. Lieut.-Col. S. S. Weatherbee, of the Militia Department, as superintendent of the plant, is in charge of the manufacturing equipment. Under the direction of this staff the engineering, architectural, and construction work was performed by Westinghouse, Church, Kerr & Co., Montreal and New York, to whom we are indebted for the foregoing data.

GROUP OF FEMALE EMPLOYEES, CAR DEPARTMENT, C.P.R. ANGUS SHOPS, MONTREAL.

FRICTION CLUTCHES—II.*

By W. G. Gass.

IN our Jan. 18 issue a resume was given of the different types of friction clutches manufactured, examples of which are to be found installed in lesser or greater number as part of the transmission equipment of general industrial and metal-working plants. The driving surface feature was discussed at some length in the same issue.

Clearances

Clearance is the main difficulty in the general run of clutches, and the smallness of it is the cause of a considerable amount of wear when running out of gear. In all cases where the setting-up is done by screws, the clearance between the driving part and the driven is a relatively small amount. The cone gives the largest amount of any, and on that score alone is the best. In segment clutches, both inside band and outside band clutches and plate clutches, it is a very serious problem. In the majority of these where a screw is used, the usual amount of rotation of the screws is about 1/8th of a revolution, and if screws of, say, 1/4 in. pitch are used, right and left hand, the movement given to the segment is 1-16th of an inch 1-32nd on each side, and that represents the clearance when the clutch is out of gear; the actual clearance is less than this owing to the shape of the segments.

*Read before the Manchester Association of Engineers.

Setting Up Gear

In all cases the action of setting up a clutch is the conversion of a sliding movement along the shaft carrying the clutch into a pressure between the clutch surfaces. This may be properly divided into two portions, the first that which is in the clutch itself, and the other by which the power for operation is applied. In the majority of clutches the locking and concentration of power obtained by the toggle motion is the one mostly adopted, and when once set up has no tendency to slip back. It requires in every case an adjustment by means of a screw which can be set so as to bring the levers in the correct position to give the requisite pressure on the surface.

In most of the internal and external segment and band clutches the adjustment is obtained by moving the main nuts a portion of a revolution and relocking—the nut having a serrated rim with a locking pin. In plate clutches it is generally done by using the adjustment screw at the point where the pressure to the plates is applied. In others, the forcing of the surfaces in contact is done by a wedge, having at its larger width a parallel portion which takes the end thrust off when the clutch is set up. The wedge is flat in some and circular in others.

With both the toggle point and the wedge, a sliding block is necessary to transmit the power from the stationary lever to the rotating shaft carrying the cluch. In the majority of cases the power is applied to the clutch to set it in gear, but, in others, the power is applied to release it or put it out of gear, the clutch being kept in gear by means of springs. Motor car clutches are the most common examples of this kind. For general machine driving, where a rapid movement is required for operating the clutch, a lever is usually employed, and if the leverage be sufficient, is quite satisfactory. It enables the power to be applied quickly and as quickly released, and where it is desired to give a slight movement to the machine, and also where the clutch is put in gear and released many times. Where a clutch is in gear for long periods, a screw and quadrant is mostly used. This is as generally fitted to internal combustion engine drives. It gives an easier starting movement because the pressure can be more gradually applied, but it is much slower both at starting and releasing. Where the lever is used, particularly on a heavy clutch, it requires a strong pull on the part of the attendant to put the clutch in gear. The trouble with all setting-up gears is the wear on the pins and lost motion due to clearance in bearings.

Pressure on Working Faces

This is the crucial point in the efficiency of any clutch and its power to drive, for unless the necessary pressure exists between the frictional faces the clutch cannot transmit its power, and it is here where so much trouble arises in the use of any form of friction clutch. The power of any clutch is of course dependent on the co-efficient of friction between the surfaces, and whether they are dry or lubricated, and it is this factor which so materially affects any formulae for the power of a clutch. The co-efficient of friction varies greatly with the state of the surfaces, and, after the surfaces become glazed the power of the clutch drops in unison.

It is usually considered that if an actual pressure of 50 lbs. per square inch can be put on the surfaces it is as much as is desirable for good working conditions; but, if for any reason a less pressure is put on than that required to transmit the power, a clutch will, if it begins to slip, grind itself away quickly, and in the spring centre type grind away all the available spring in the metal. On looking at the action of the toggle joint it will be seen that the travel of the portions of the clutch being set up is very slight at the end of the movement, when the thrust link of the toggle is approaching the vertical. Pins are essential, and, in spite of all that can be done, will wear, so that if a clutch is set up correctly a very small wear on the pins and links of the toggle will rapidly reduce the effective pressure of the faces, even without taking into account the wear on the frictional surfaces.

It is, therefore, very necessary to keep a watch on a clutch to see that any wear which may take place is followed up, if the life of a clutch is to be as long as it ought to be. Where the pressure on the surface is due to springs, and these usually are in direct thrust, then they will follow up a considerable amount of wear themselves. It appears from this as though springs were the best, but they are only good where conditions are suitable, and this is not generally so for driving machines. The remarks about wear apply equally to wedge setting up surface. The power transmitted is proportional to the speed of rotation, and a clutch which will transmit 10 horse power at 100 revs. will of course transmit 50 horse power at 500 revs.

Lubrication

In clutches, as in everything else, lubrication is of the greatest importance, and more particularly where the clutch is running idle for a considerable part of its time. If the outside portion of the clutch is the driven part, it runs on the shaft and may have to be stationary while the shaft rotates in the clutch bushes; or, if the outside is the driver it has to run loosely on a stationary shaft. This is a fruitful source of trouble with many clutches, and the lubrication of these bushes requires the closest attention, both in design and on the part of the attendant. If the driven portion has to be stationary while the shaft runs in it, there is a tendency for the shaft to wear a groove in the bush, and, when this starts, it rapidly grows worse as this part always seems to stop at the same point and be worn oval; while if the driving portion has to run loose on a stationary shaft, the bush wears larger and affects the clearances, even sometimes becoming so bad that the friction surfaces never run clear and are always rubbing. When in gear the lubrication is not required, and the oil is liable to be driven out of the bearing surfaces and so be missing when wanted.

In starting up any friction clutch a certain amount of rubbing takes place, and when two metal surfaces rub on one another fine particles of metal are given off. These, in an enclosed chamber, cannot get away and so become mixed with the lubricant, and form an excellent abrasive which does not increase the life of the parts. Another peculiarity of lubrication in the case of plate clutches is that where the resistance to the idle clutch is not very great, if the oil becomes thick the plates adhere because all the air is driven out between them, and the resistance may not be able to make the clutch stop. Springs between the plates have been tried to get over this, but the results have not been very satisfactory. Excessive lubrication also reduces the driving power materially. Solid grease has much to be said on its behalf for lubrication of clutch hubs, but it is often difficult to employ it satisfactorily.

DETECTING FAULTS IN CASTINGS

DETECTING the presence of internal defects in iron and steel castings accomplished by a current supplied from a small alternator to the primary winding of an induction coil,this induces in the secondary winding a current which is passed through the coils of two horseshoe magnets, mounted at a fixed distance apart and movable to and fro over the surface of the casting. The fields of both magnets are affected uniformly if the structure is homogeneous. Defects, however, will disturb the lines of force from the nearest magnet. In a vibrating sounder, connected to a secondary coil on the magnet, the tone will differ in pitch from that given out from the corresponding sounder connected to the other magnet. Amplification of sound is secured by microphone attachments, enabling the observer, by means of telephone receivers, to detect the locality of hidden flaws as the magnets are moved over the casting.

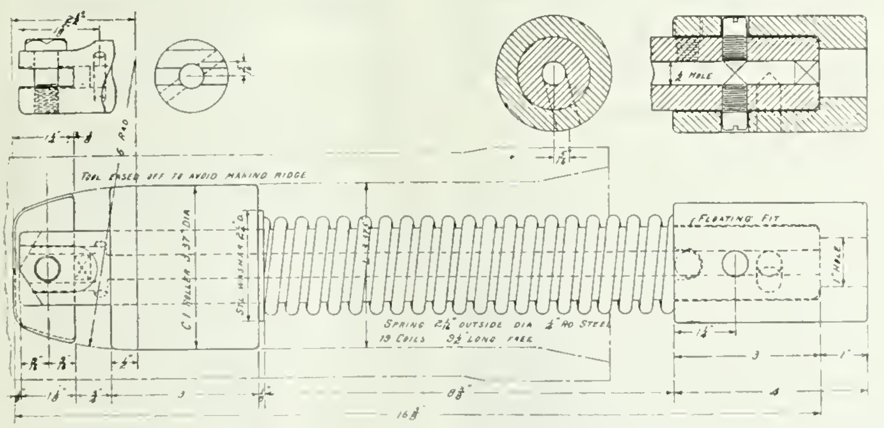
BASE FINISHING BAR

By J. A. S.

MANY manufacturers have experienced great difficulty in finishing the inside profile of 4.5 in. high explosive shells. The high cost of tool steel and the excessive wear on the point of the tool, together with the strict specifications regarding the finish of this portion of the bore, require the best efforts of shell makers to devise efficient means for overcoming this trouble, and eliminating as far as possible, all trace of tool or chatter marks.

The sketch herewith shows the method adopted by one firm, first as an experiment, and afterwards as part of the standard equipment for all machines on the boring operation. The care required in maintaining the efficiency of the spade tools is not only an expensive factor of shell production, but in many instances the loss of time through excessive grinding tends to curtail the output. As the wear on the tool is greatest at the nose, it is this portion that quickly loses its proper shape, and the purpose of the tool here illustrated is to give increased life to the finishing reamer and at the same time leave the base of the bore the exact shape and free from objectionable roughness. The short section of tool has the exact shape of the base and extends a short distance along the contour. The duty required of this tool is very light and is further assisted by the roller that steadies the bar while the tool is cutting. This roller rides free upon the bar and is slightly smaller than the bore of the shell, a short portion at the front being turned to fit the finished profile. The spring shown, acting on the steel washer, forces the roller against the profile and holds the bar in a central position, while serving as a support close up to the working point. The bar is not held rigid but has a floating fit in the turret. This device is proving most efficient and previous troubles are almost entirely eliminated. Provision for supplying cutting compound is shown in the sketch although experience has shown that the tool can be run dry with equal satisfaction.



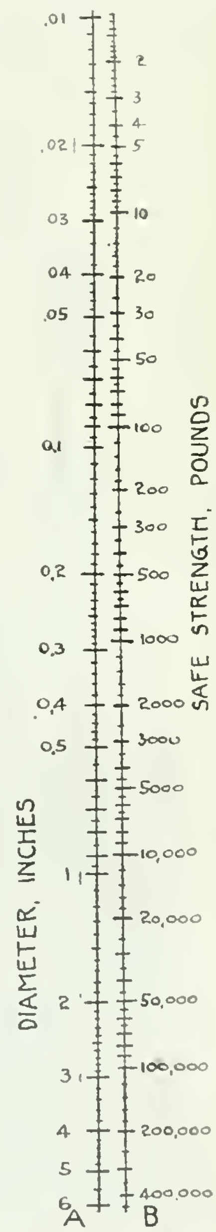
SHELL BASE INTERIOR FINISHING BAR

TENSILE STRENGTH OF ROUND STEEL RODS

By N. G. Near.

THE scale illustrated will be found handy for determining the strength of round steel rods in tension. Simply glance across from column A to column B, and the strength is given for any diameter from 1-100 of an inch to 6 inches. For example: "What is the safe strength of a steel rod one inch in diameter?" Column B shows it to be 12,500 pounds.

The scale is based on 16,000 pounds per sq. inch, which is the commonly used safe strength for steel. Inversely, the scale may be used to advantage when determining the size of rod necessary to withstand a certain stress. For example, "What diameter of rod should be used to hold up 50,000 pounds?" The answer is, a 2-inch rod.



ROUND STEEL RODS CHART FOR TENSILE STRENGTH

OBTAINING DRAFT WITHOUT HIGH CHIMNEYS

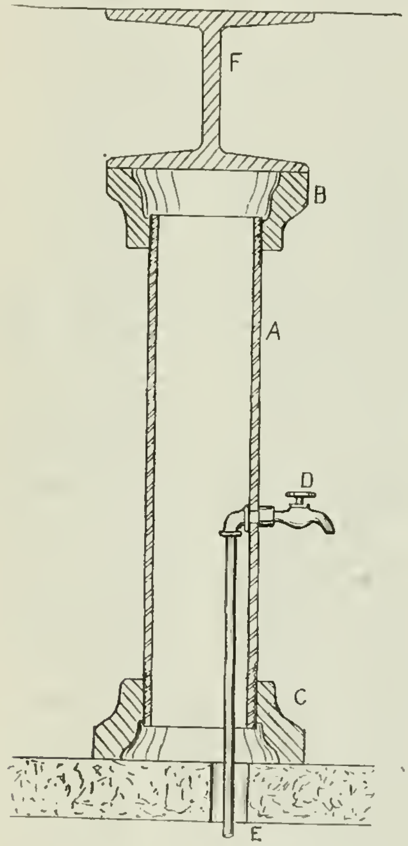
By E. T. S.

ON page 82 of your issue of February 1 is a short article entitled, "Obtaining Draught Without High Chimneys," that merits, in my opinion, more than ordinary attention, by reason that the author either has discovered something radically new in draught producing apparatus, or else he omitted to localise the case in question, in which case, the term "ordinary practice" is out of place.

Now, it is a fact that in "ordinary practice" the purpose of a chimney or stack is to "make the fire burn," in other words, to provide sufficient draught to produce complete combustion of the fuel under the boiler. Also, in the second case it carries off all obnoxious consumed or unconsumed gases. So far, I agree with our friend who now remarks, "so far so good, but this leaves in many cases much to be desired." I would like to ask what it is that is left so desirable? To continue, we read that the most efficient heating is secured by reducing fuel to carbonic acid gas. Quite true, but to produce this state in the furnace, our friend states that it is necessary "that large volumes of air must be drawn through the fire at comparatively low velocity." This statement is extremely broad, even omitting the fact that the information given is "general." We know that, for every pound of fuel consumed, a certain determinate amount of air is necessary for complete combustion. Perfect combustion is attained when the correct amount of air is admitted through the fire and also over the fire.

The next paragraph in the article says that, "The best method of providing the necessary air for combustion is by means of an exhaust fan." Before proceeding further, I would like to ask, what the difference between the two draughts is to the furnace, supposing both are designed to produce the same pressure, or, whether our friend considers that a chimney draught is superior to a fan draught by reason of its origin alone. The question is absurd, because if either be designed to give a certain draft in inches, the furnace cannot detect the difference.

The subject is a live one to-day, even as to the merits of the two systems. The fan system is favored chiefly on account of the low installation cost. The chimney is high in first cost, but has a maintenance cost of practically nil; on the other hand, maintenance cost of an induced fan system is endless. In this country where we are subject to severe winter temperatures, most of us drive our boilers pretty hard in the winter. The fan is speeded up above ordinary, and, if anything happens it is liable to be serious. The chimney acts in a way, more or less automatically with you.



ADJUSTABLE SUPPORTING POST.

The intensity of the draught depends on the difference between the inside and outside temperatures, and so up to a certain point the draught increases as it gets colder.

I do not pretend to understand our friend's system of stacked brushwood kept watered, unless it is intended at the air intake end of a forced draught system. Perhaps he will enlighten me?

I have written more than I intended, but it must be obvious to anyone that now-a-days a stack is not just "guessed at" for size or anything else, any more than an induced draft or forced draft system would be installed so thoughtlessly. It is the cost, the ultimate cost that counts, and these involve careful calculations and painstaking consideration.

ADJUSTABLE SUPPORTING POST

By L. U. N.

AN adjustable pipe post is shown in the accompanying sketch, made from 6-inch steam pipe threaded right hand on one end and left hand on the other. Two heavy cast iron flanges are shown on the ends at B and C. This post can be placed under a ceiling or I beam already in place and by using pipe tongs to unscrew the pipe a few turns, a tight bearing can be made, the flanges being held with chain tongs while the pipe is being unscrewed.

In the post shown, a hole has been made in the concrete floor at E large enough to allow the elbow on the water pipe to pass through, a hole being drilled in the post to allow a nipple to pass through freely, and a drinking tap connected as shown at D.

EXAMPLES OF FORM GRINDING

FORM grinding is coming into more general use for the rapid but accurate production of irregular shaped or formed surfaces. The operations employed may be cylindrical, surface, internal or even occasionally off-hand.

The pins on crankshafts are roughed from the forging and finish ground on cylindrical grinding machines. The fillets are formed by the grinding wheel.

The cams on an integral cam shaft are another example of form grinding. Here the wheel face is not formed but parallel to the spindle. The cam is formed by means of the rotation of a master cam against a roller which actuates the cam shaft so that the cams are properly formed.

Cast iron pulleys may now be crowned by means of a formed grinding wheel. This method of crowning with a curved face is much superior to the old method of turning two flat faces, with a sharp ridge in the centre. The round crown is easier on belts and makes a far more powerful drive.

Grinding the nose of shrapnel and high explosive shells is a new and interesting development of form grinding. The face of the grinding wheel is formed by means of a radial truing device to the exact curvature of the nose of the shell and fed straight into it.

Among other articles that are frequently "form ground" might be listed, valve stems, cream separator bowl shells, rifle barrels, transmission shafts, electric starter and armature shafts and other multiple diameter shafts.

The grinding of marble mouldings on a planer type surface grinding machine with a formed wheel makes possible some of the beautiful marble interior decorations seen in our latest offices and public buildings. A series of formed grinding wheels may also be used cylindrically in shaping marble columns, balustrades or pilasters used in ornamental architecture.

In the very latest machinery for the accurate forming and finishing of gear teeth, the designer has again called upon the grinding wheel. Now formed grinding wheels are employed for this purpose with the result that our gears are running quieter and more smoothly. Large cast iron gear teeth are occasionally roughly formed by means of hand grinding.

One of the most important and far reaching applications of form grinding is found in the gumming or sharpening of circular and band saws. This operation is so common that we seldom think of it as form grinding, but, nevertheless, the wheel is formed so that the teeth of the saw may be properly shaped.

The salvaging of worn out saws, cutters and reamers again calls upon some operation of form grinding to make these tools practically as useful as they were when new.

Grinding the groove in ball races is a form of grinding operation, whether it is done cylindrically, internally, or by surface grinding. A formed grinding wheel is used and these operations call for very accurate and smooth work.

The grinding of splined transmission shafts presents, perhaps, the most difficult kind of form grinding. It is necessary to grind both straight and circular surfaces at one traverse of the wheel, and is essentially a surface grinding operation. Of course a special truing device is necessary to keep the faces of the grinding wheel trued to proper shape.—*Grits and Grinds.*

HERAULT FURNACE INSTLLATION

AMONG recent installations of Herault furnaces in Canada, the following are to be noted:—

The Dominion Steel Foundry Co., Hamilton, Ont., are installing four 6-ton furnaces for making war material. After the war, metal from these furnaces will be used to make wheels, tires and axles.

Armstrong, Whitworth, of Canada, Ltd., are installing one more 6-ton furnace, making three of this type and capacity, at their plant, Longueuil, Que. War material, as well as tires, wheels and axles constitute the product.

The Imperial Munitions Board will install ten 6-ton furnaces in their new plant at Toronto. The steel will be used for making war material.

The shrinkage of manganese steel amounts to 5-16 in. per foot as against 3-16 in. to 1/4 in. in ordinary steel foundry practice.

When several furnaces are tapped into one ladle before pouring, the content of the ladle is apt to become too cool. According to the *Iron and Coal Trades Review*, the metal can be kept hot very conveniently by using an apparatus invented by M. C. A. Keller, of Paris, consisting of two electrodes which can be raised and lowered from a crane or gantry. Current passing from one electrode to the other through the contents of the ladle generates enough heat to bring the contents back to the proper pouring temperature.

Safe Practice at Blast Furnaces and Its Development-III.

By Frederick H. Willcox

In its efforts to increase safety in the metallurgical industries, the Bureau of Mines, Washington, D.C., has been studying the causes of accidents at blast furnace plants also methods for their prevention. This article describes the known dangers and makes suggestion of means whereby the risk of accident may be lessened or, better still, wholly avoided.

THE STOCK-HOUSE CREW

ROD the furnace regularly, and, in, case it is hanging or stiff, report to the foreman promptly. If anyone is working in the skip pit, or the skip incline, hoist, or skip, don't move the skip, except under direction and after giving warning. If an oiler or "handy man" is working on the sheave wheels, bell rods, hoppers, distributor mechanism, or bell-rod cylinders, do not lower the bells except on signal from those on top. Never start the skip or hoist cage until you receive the proper signal, unless you have all regular charging operations in sight, and then signals are not required. When the blast is off, or when the furnace is shut down and men are working about the top or bottom, do not fill the furnace or lower the bells without warning the men away from the tuyères and hoppers on top, and then only under the direction of the foreman. If the furnace is being shut down or if it is working irregularly and stops taking charges on account of hanging and slipping, do not put wet ore on the bell; at many plants it is considered dangerous to dump wet ore when the furnace is low. Report anything about the skips, bells, or indicators that does not seem right, such as skips striking the bumper blocks too hard, or frayed cables, irregular, slow, or quick movement of the bells, or water in steam lines. By early notice an accident or possibly a hazardous delay may be avoided. Never let anyone go up the skip incline to the top alone.

Scale Car Operators

Scale-car operators should watch for stock-house cleaners or others crossing the track and should always have the car under control. Watch out for overhead obstructions. Let the furnace millwright or electrician do all repair work on the car. Be careful not to leave ore or stone on the edges of the chutes; many accidents are caused by stock falling from the chutes. When barring or punching at the chutes or doors of the bins be careful to avoid a rush of ore or stone falling on your foot. Do not open the door of a nearly empty bin or get under it just as the car doors are dropped on the trestle; the material may easily fall through and bruise you, or if it is flue dust or sinter, burn you. Wear goggles when the coke is very dusty or when breaking ore or limestone. If steam is used to thaw ore in the bins or piles be sure that the hose is strong and in good condition. See that no one is in line with the nozzle when you turn the steam on. If gas is used see that it stays lit and that a pocket of gas does not accumulate. Do not light gas by hand with a match, use burning waste, placed on the floor or in the chute.

Ore Buggie Accidents

Most accidents with ore buggies happen from catching the fingers between the buggy handle and a column, wall, or other obstruction. Watch out for this and use safety handles. Be careful not to let the buggy leg come down on your heel, or to run the wheel over someone's foot. Never race with a buggy, you may easily lose control of it and receive a wrench, strain, or bruise. Watch that your fingers or feet do not get caught between a lump of stone or ore from the chute and the buggy or floor. Don't undercut an ore or stone pile, or let the stock lodge above you, keep it knocked down with a bar. Never stand close to the elevator pit as the cage comes down, ready to take the buggy off the instant the cage comes to rest, as many men have had their feet crushed in this way by getting them caught between the cage and the floor sill. Don't try to get on the cage before it has come to rest, or after the signal for hoisting has been given.

When it is necessary to clean the skip pit, notify the skip operator and do not go into the pit until he tells you to. Avoid walking under bin doors and chutes. Keep off the scale-car track and watch for the car when crossing the track. Don't stand on the track when signaling the car operator. Be careful that your bar does not touch a third rail or trolley wire. It is best not to ride on the scale car, and you should never jump on or off the car when it is moving.

When you enter the motor house or hoist-engine room notify the skip operator, both on entering and leaving. Stay at your own place of duty, even when you are "spelled off." Keep away from the cast house and stoves unless you are required to go there to help. Report all bad places to the foreman, such as dark corners, overhead obstructions, poor track, holes, and unsatisfactory bin doors. Be sure to report every injury, as even a slight injury if neglected may have serious or fatal results. Even a bit of coke dust may seriously injure the eye if not taken out right away. If a man receives an electric shock free him from the source of current, being careful not to get a shock yourself, give him artificial respiration at once, and send for the foreman. Similar first aid is needed if anyone becomes gassed while working on top.

Hand Filled Furnaces

On hand-filled furnaces, top fillers should remember not to step over trap or lift doors at the top of elevator shafts while the elevator is running. The safety of many men about a furnace plant depends indirectly on the care and interest the stock-house crew take in their work. Careful weighing, regular charging, reporting any difference in appearance or quality of coke or limestone, and constant watching of the movement of the charge in the furnace will prevent many slips, "messes," and dangerous work at the tuyères, tapping hole, and furnace top.

FIG. 21 SAFEST WAY OF USING POLE TO PLACE CARS

Trestle Gang and Yardmen

Watch for the lorry car, locomotives, and cranes, and do not go under the ore bridge just before ore is dumped into the bins. Do not jump on or off moving cars; many men are hurt that way every year. Never sit on or near the track or bridge rails to rest; find a safe place. When you hear the warning whistle at the furnace get out of the car at once and under shelter as it means the furnace is hanging and may slip. When ore is being dynamited and a warning is shouted, get under cover and stay there until material has stopped falling. Do not try to jump across the bins from rail to rail; use the crossovers. They were put there to use, and the minute saved by not using them is worth less than the good example set by using them.

Do not use a pole in spotting cars with a transfer car or locomotive on an adjoining track, use a cable with safety hand locks. If there is no cable and a pole must be used, stand on the same side of the pole that the coupler of the car is on (Fig. 21). Be careful in pinching cars on the trestle, you may fall and receive a severe injury. Pinch a car the way the foreman has shown you, and report pinch bars with smooth heels or dull points to the toolman or foreman. The safest pinch bar (Fig. 22) is one fitted with a disk and tool-steel heel. When turning on a steam jet to thaw ore see that no one is in line with the jet; use a clamp to hold the nozzle, and avoid working with worn hose. Watch that cinders from trestle locomotives, or hot coke, do not start fires in the coke bins or walks. A safety car wrench for opening drop doors on cars is shown in Fig. 23.

FIG. 23. TRESTLE LABORER USING SAFETY CAR WRENCH. WHEN THE SHAFT BEGINS TO REVOLVE, THE HINGED JAW RELEASES. DISC IS TO PREVENT MAN'S HAND STRIKING CAR, AND SHORT BEND ON END OF HANDLE PREVENTS USE OF PIPE EXTENSION.

Loaded Car Drop Doors

It is dangerous to open drop doors on loaded cars unless you know how. Do not try to do it until you have been shown and, if possible, have watched for a day men who knew how. Before getting into a car to unload it, or crawling under a car to work on the drop doors, make sure, by asking the foreman or "straw boss," that the car will not be moved. Wait until the doors are dropped before going on top of material in cars to be unloaded. When unloading hopper cars, do not stand over doors or on the edge of the material; it may slip and carry you down into the bin, where you may be suffocated or severely injured. Obtain a firm footing in the bottom of the car between the doors, or be sure of a firm hold on the side of the car. By all means wear a belt and safety line if these are provided. Do not undercut material any more than is necessary and watch that the lumps do not catch you. Be very cautious in opening the doors of cars loaded with flue dust; if dry, it will fly out. Avoid stepping on flue dust in cars, for even apparently wet dust may be dry and hot beneath and cave when you step on it. Always get out of a car the same way you get in; do not crawl through the doors in the bottom of the car (Fig. 24).

Miscellaneous Precautions

Before you drop material into empty or nearly empty bins, notify the stockhouse crew so they can keep clear of falling material, and be sure that the bin doors are closed. In poking ore in bins and chutes see that you will not get caught in case a fall of ore catches the bar. Never go into any bin to shove material or to clean the bin unless you have a belt with a life line attached to a girder or tie (see Fig. 25). Use a flag or track torpedo to protect the bin you are working in, or ask the foreman for a watcher to hold the line and warn men not to dump material in the bin or run cars over it.

Do not work with a pick or sledge if the handle is cracked or the head loose. Do not use a bar, wedge, or sledge having burrs or splinters; give it to the toolman. Watch that your tools do not touch electric conductors. When carry-

FIG. 22. TRESTLE LABORER USING SAFETY PINCH BAR FITTED WITH DISC, A. SHOULD THE BAR SLIP HIS KNUCKLES WILL BE PROTECTED.

ing bars, pipes, or other material through doors be careful so as not to strike persons passing by (see Fig. 26).

Avoid leaving tools, scrap, boards, lumps of ore or stone, or sheet iron, on the walks where they may cause some one to stumble, or fall into a bin or into the stock house. Coke forks or shovels should be placed with the edges or prongs pointing to the floor. Report to your foreman any rotten, loose, or burned planks in the walks, or defective lights. When you are set at new work be sure to ask about the work, the way to do it, and the dangers connected with it. Do not ignore danger signs; they mean what they say. Do not wrestle or play when at the plant, especially when on the trestle, where you may fall into a bin or the yard.

FIG. 24. UNSAFE PRACTICE; CRAWLING OUT OF HOPPER CAR THROUGH HOPPER OPENING.

Men working in ditches and excavations should work far enough apart to avoid any risk of striking one another with picks or other tooks. (See Fig. 27.)

FIG. 25. PROPER EQUIPMENT FOR MAN WORKING IN ORE BIN. NOTE LIFE LINE ATTACHED TO HIS BODY AND TO CROSS BEAM OF BIN.

FIG 26. SHOWING DANGER TO PASSERS-BY WHEN CARRYING BARS, PIPES AND SIMILAR MATERIAL THROUGH DOORWAYS.

Before leaving an excavation for the night or for other work cover the hole with planks. Manhole covers should always be replaced when a job is done, or even when leaving the job for a short time. (See Figs. 28 and 29.) If you are chipping concrete, wear goggles, as chips frequently fly in the eye. Don't undercut piles of ore or stone, or piles of frozen earth, sand, or other material. Don't undercut banks when excavating; keep them knocked down; test the edges with a bar and knock or pry any loose earth down (Fig. 30). Frozen ground is especially dangerous.

Stay out of cast houses, pig machines, boiler houses, and other places where your work does not require you to go, and keep away from iron and cinder ladles when they are being shifted. Whenever possible, keep from under cranes in operation. Always warn the crane man before beginning to clean the tracks about the granulating pit, as he may accidentally drop some hot slag over the sides of the car unless he knows you are beneath, or scalding water may run from the grab bucket as it is carried over your head. Be careful in cleaning up about a loaded cinder car, as steam and scalding water may escape suddenly from a drop door. Don't throw wet or damp rubbish into cinder ladles, as it may cause an explosion, and in turning a hose on a leaking cinder or iron ladle stand as far away as possible, as you may be scalded by steam or burned by an explosion or "shot" if the water hits molten iron. Avoid walking on ash piles; they may be hot underneath and burn your feet if you break through. Keep your feet out of flue dust when cleaning it up. In loading or unloading cars, see that the gang planks or runways are in good condition and are properly placed and secured.

Be careful when handling heavy material or using tools (see Figs. 31 and 32), as most accidents about blast-furnace plants are caused in such work. When necessary to go on a roof or window ledge to clean windows always use a safety belt and a life line. When cleaning windows from a ladder do not overreach; go down and move the ladder if necessary. Be sure that the ladder is resting squarely at the bottom so that it can not slip. If the ladder is a long one have some one steady it. Always have at the top a cross piece long enough to span the entire window. The cleaner you keep the yard the better and more safely everyone can do his work. Don't let piles of rubbish accumulate, or pieces of lumber, brickbats, scrap, and other material lay around, or leave tools about; some one may stumble over them. Fill up small holes and depressions and report promptly any steam or hot water puddles caused by leaky lines.

Pig-machine Men

Always wear goggles or a mask when working about the troughs while iron is being poured; be cautious when the molds are cold or if they have ice, snow, or water in them, and, especially when cinder is coming over, keep away as much as possible. When it is necessary to work under the strands to knock out the "stickers," keep from directly under the strand as much as possible, both the one you are working on and the adjoining strands. Men tending the lime vats and sprays should watch for stickers when it is necessary to go under the strands to adjust the sprays or to feed lime, while the machine is running. Aim to do such work between casts and shut off the steam when working about the sprays or vats. Before pouring, examine the top of the ladle to see that there is no solid crust of cinder or iron frozen over the hot metal. Such crusts should be broken with a warm, dry bar, as otherwise the metal will splash badly when it breaks through the crust. Never operate the motors, clutches, or hoists for pouring ladles or running the strands unless it is your job, or unless you are told to do so by the foreman. Keep away from around the sprocket wheels. Remove the scrap and clean the rails between pouring ladles or casts. Don't try to save a few seconds by stepping on or across molds in motion or containing hot metal; use the walks or go around if necessary. Be sure that the bars you use with which to bar scrap out of the troughs are dry and warm, and avoid using short poling sticks. Before releasing the ladle after pouring, replace all safety dogs or legs in position.

FIG. 28—WORKMAN LEAVING MANHOLE UNCOVERED

FIG. 27. EXCAVATION OR DITCHING, SHOWING LIABILITY TO SERIOUS ACCIDENT IF MEN WORK TOO CLOSE TOGETHER.

When you are working about the rear of the machine, wear goggles to protect the eyes from flying chips of iron or lime dust. Use care in loading cars to prevent side loading, overloading and loading directly upon drop doors, and see that no pigs are left on the end frames where they may fall off.

When working on the pig-machine strands, or changing molds, see that motor switches are locked open, tagged with a danger sign, or that the clutch is fastened open. Avoid touching electric lines, motors, or light sockets, for where there is so much steam and metal floors as are about pig machines, you may get a severe electric shock or burn. Keep sledges, cutters, and other tools in good condition, be careful in using them, and watch your hands and feet when handling molds or pigs. Report cuts, burns, or bruises promptly.

Ladle-House Men

Don't leave large pieces of scrap on the ladle spouts, they may cause accidents in shifting or pouring, and in removing them use a long bar and keep away from in front of the ladle; work from the side. Before trying to remove a bottom skull, clear away all overhanging rim or side skulls and knock out any loose bricks. The bottom skull will then come out more easily and safely. Before removing a skull or cleaning a ladle, be sure the ladle is securely blocked or propped. When trying to lift a rim skull out of a ladle with the crane, don't stand on the rim of the ladle, the hook may slip and strike you or cause you to fall. Watch all ladles for iron frozen on the rim or spouts, skulls, and "hot spots," or signs of failure on the lining whereby hot metal might break through. A thin place in the lining is usually shown by the ladle shell becoming rusty red.

Do not clean hot kish or metal from ladles onto damp ground; to do so may cause an explosion. When cleaning a ladle into the quenching pit use a long-handled scraper and keep as far back as possible. Take time to pull the cleanings out slowly and keep them from running out suddenly if they start to slide. There is no danger of an explosion if the cleanings are fed into the water intermittently and in small quantities and not too fast. An accumulation of unquenched ladle cleanings beneath the water or a rush of cleanings may explode. To guard against sparks or small splashes wear goggles or a mask. When playing a hose on hot scrap or ladle cleanings, stand as far away as possible to avoid steam or small explosions. If you dry ladles with gas, do not try to light the gas with a torch: kindle a small wood fire or throw burning waste on the ladle before turning the gas on. Always examine a relined

FIG. 29—PASSER-BY FALLS IN MANHOLE LEFT OPEN BY OPERATOR

and dried ladle that has been standing about before using it; if it seems to be damp inside, build a fire in it or dry it again. A damp lining will probably cause boiling, leaks, or explosions of hot metal. Always report water in cinder ladles.

Do not work inside of a ladle without notifying the crane man or placing a sign to show him you are inside, so that he will not carry loaded buckets over you. Use hooks or tongs in handling heavy pieces of scrap. Gloves or hand leathers, except safety hand leathers, should not be used, as they may catch and cause you to fall. In hooking on scrap to be lifted with the crane see that you do not catch your hand. When breaking scrap with a steel drop ball get behind shelter and place danger signs to warn others from flying pieces. In steadying heavy crane buckets use a hook or a long-handled shovel. Do not stand close where you may be crushed or caught between the bucket and some other object.

FIG. 31. UNSAFE WAY OF HOLDING BAR FOR A SLEDGE. MAN HOLDING BAR IS STANDING ON SAME SIDE AS STRIKER.

Slag-dump Men

When dumping cinder ladles at dumps, pits, or conveyors, keep away from the front, as the cinder will splash to a great distance. Never pour cinder on flue dust or refuse coal; to do so may cause a great burst of flame or an explosion. Never try to remove a "sticker" or apparently solid skull from a cinder buggy or ladle that has just been brought from the furnace to the dump; the sticker is probably molten inside, and if it does not fall out itself when the ladle is tilted and you try to pry it out, it may burst and splash hot cinder on you. Before working on such a ladle report the sticker to the foreman. He will, if necessary, set the ladle aside long enough for the slag to harden, when it can be pried loose without danger from burns.

Engine Room Force

Before changing blowing engines on a furnace first notify the furnace blower unless it is an emergency change on account of a breakdown. In case of a stop at the furnace keep at least one engine turning over at sufficient speed to avoid any chance of its being stalled. Watch that the flywheel does not turn backward owing to the back pressure of the blast; few blowing engines will do this, however. By keeping an engine turning over against the butterfly valve in the cold-blast main with the snort valve open, there is the least chance for an explosion or fire in the cold-blast main and air tubs.

In case two or more furnaces are blown from one room, attach a number to each engine showing the furnace it is blowing to avoid any possibility of confusion in checking the furnaces. When the furnace whistle is blown for a check, observe the signal light or number as well as the whistle before checking the furnace. In case of a shutdown when the engines are stopped, close the stop valves between the air tubs and the cold-blast main. In case there is a steam connection to the cold-blast main, examine the connections at the beginning of each turn or shift to see that both air and steam connections are in working order and that no steam is leaking into the main. Always be ready to turn steam into the blast main if the signal or word is given. Place numbers at each steam inlet to correspond to the furnace number. Always be ready to check the engines promptly; at times, conditions at the furnace demand throwing the snort valve open very quickly and getting the wind off as fast as possible.

Before entering a cylinder to make repairs, lock the steam throttle and the vacuum stop valves, place blocking in the cylinder, and block the flywheel fast. The drain valves should be opened prior to taking off the cylinder head. In undertaking repairs to gas engines, be sure that the gas valves and water seals to the engine are closed. It is essential that two men should work together in repairing gas-engine parts that are inside the cylinder, are near gas or inlet valves, exhaust lines, or are in enclosed places, such as basements and tunnels. Be prompt in shutting down gas engines when the signal is given, as there is even more danger involved in delay with gas engines than with steam engines.

Oilers and wipers should wear closely fitting clothing that can not be easily caught in the moving parts. In wiping and inspecting the engine, watch that you do not get caught by rocker arms,

FIG 30—MAN CUTTING TOO FAR BENEATH BANK OF EARTH; A DANGEROUS PRACTICE

wrist plates, eccentric rods, and Corliss or other valve mechanisms. Be careful that you do not slip on oily platforms and steps, and be prompt to report equipment out of order or in a condition dangerous to employees or the plant, such as valve wheels without lock nuts, steam leaks, worn or oil-soaked governor belts, broken steps or railings, defective indicators or gauges.

Remember that uniform and correct speed of the blowing engine has much to do with the regularity of the furnaces. Irregular speed causes slips and other serious troubles. Report immediately to the blower any trouble with the pumps and tuyere-water supply so that he may be prepared to take care of the furnace in case the flow of water becomes slack or fails.

Do not put any engine or machinery in motion without seeing whether anyone is in a position to get caught or struck. Do not work on electrical equipment or touch wires unless advised by the electrician. Let the electrician fix the lights. In working above, be careful not to drop tools or leave them where they may fall on someone below. Keep from under loads carried by cranes. When the crane is being used, one man only should have authority to signal the crane man to hoist. The crane man should try to hoist straight, but, as the crane is usually high, heavy loads may swing, so it is best to keep at a safe distance when he starts to hoist. Do not tighten bolts in leaking flanges on live steam lines except under the direction of the master mechanic. Be careful in placing a ladder before using it, and if there is any danger of its slipping have someone hold it. Do not carry tools or material up or down a ladder; use a hand-line. (See Figs. 8 to 10). Return mushroomed or burred chisels and other defective tools; report or remove rounded nuts and be careful not to use too large a wrench or one with spread jaws. Don't pull on a wrench when you are in such a position that you may lose your balance and fall if the wrench slips.

FIG. 32. SAFEST METHOD OF HOLDING A BAR.

ABRASIVES, ASBESTOS AND BRICK

ACCORDING to statistics compiled in "Mineral Resources of the United States, Calendar Year 1915," the production of abrasives increased by 33 per cent., the imports decreased by 26 per cent. The term abrasives comprises millstones, grindstones, oilstones, etc., emery and corundum, diatomaceous earth, kieselguhr, tripoli, pumice, and also diamond dust and bort. In value the emery and corundum exceed all the other products by far, and the low imports are primarily ascribed to the unsettled conditions in Turkey and Greece and to the war in general. Westchester county, New York, supplies most of the emery. Tripoli is the porous, almost purely siliceous rock resulting from the leaching of highly siliceous limestones or of highly calcareous cherts. By silica the statistics of the United States Geological Survey understand quartz, sand, flints, and some of the abrasives just mentioned, all these materials being used in pottery and glass-making, as flux, and as fillers in acid towers, paints, soaps, etc. Sand-lime bricks are coming more into favor; nearly 180,000,000 of these bricks were made in 1915 and valued at $1,135,104; the State of Michigan leads in this industry. The asbestos produced in the United States in 1915 amounted only to 1,731 short tons, valued at $76,952; but the increase over the previous year in bulk was 39 per cent., and the increase in value over 300 per cent., the latter part being due chiefly to the mining in Arizona of chrisotile, an asbestos of the cross-fibre type which can be spun. So far asbestos had been exported from Canada to the United States free of duty. In March, 1916, however, Canada put an embargo on shipments of asbestos to ports other than British and Allied; the embargo has since been modified, but American miners have been looking around, especially in Vermont, the asbestos of which occurs in the same rocks as in Canada.

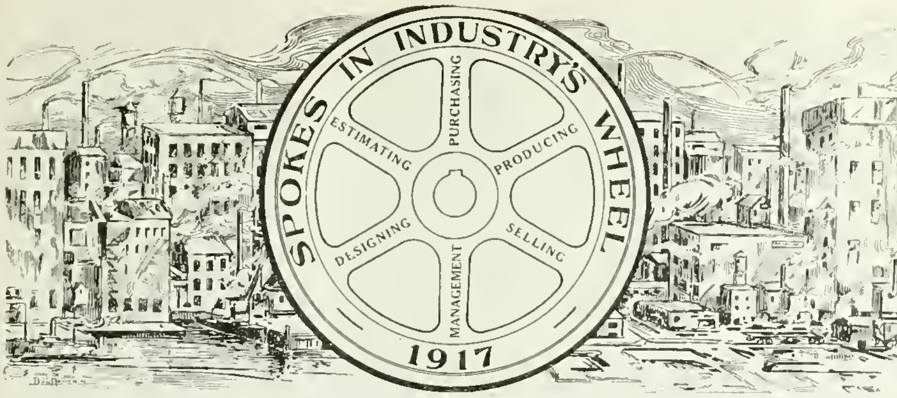
SPECIAL TRIBUNAL FOR BUSINESS MEN

A DELEGATION representing Canadian manufacturers, wholesalers and retail merchants waited on Sir Robert Borden and Sir George Foster at Ottawa on Feb. 7, and asked for the establishment of a tribunal somewhat after the plan of the Railway Commission before which the producing and distributing interests of the country would have a right to go to answer charges affecting their business. The delegation which consisted of some forty members, was introduced by Senator Lynch Staunton, and was received by the two Ministers mentioned, and by Sir Thomas White, Hon. C. J. Doherty, Hon. J. D. Reid, and Hon. Martin Burrell.

What the business men want is a court before which they could answer charges as to price raising, the formation of combines, etc., instead of being brought before the common courts of the country as at present. The delegates stated that under the present system important business details sometimes have to be improperly divulged and that unwarranted odium attached to it for the merchant so accused. Such a tribunal as they proposed would report to the Government the merits of every case brought before it and that report could go to the Attorney-General of the province concerned, who would thus have before him the results of capable preliminary examination as a guide in prosecutions. The delegation, it is understood, also opposed the cost of living investigation as at present carried on.

Sir George Foster, in reply, asked the delegates to submit practical suggestions as to how what they asked could be carried out. If such suggestions are received, it is understood there is every possibility that such a tribunal as asked for would be created.

Shortage of Leather.—Canadian industry and ultimately Canadian consumers, are facing shortages of a number of commodities needed in production by this country. The latest to be heard from in this connection are the leather men, who waited on the Government in Ottawa, on Feb. 8, to ask that something be done to meet the scarcity of hides. A situation almost equally serious exists with regard to wool, while there is also a growing scarcity of machine parts, tool steel, tin sheets, wire rope, and a number of other such articles. These were formerly obtained from England and their import has been stopped by the English restriction of exports.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

JAMES ALFRED STAIRS

THE Province of Nova Scotia, with its half million inhabitants, affords a typical example of modern industrial growth. At one period exclusively a farming and fishing region, the province possesses now something like 1,500 manufacturing establishments. The industrial ascendency of Nova Scotia is broad based upon its immense deposits of coal, its forests, its farms, its fisheries, its water powers, and its strategic commercial situation as the Eastern gateway of Canada. Its position on the fringe of the Atlantic Ocean highway, and, therefore, its proximity by sea to either European or American markets, the year round, constitute, of course, a most valuable asset. That this was recognized by the early settlers and continues to be demonstrated by each succeeding generation, the present-day achievement record amply proves.

James Alfred Stairs, vice-president and works superintendent, the Eastern Steel Co., contracting engineers, New Glasgow, N.S., a "Spoke in Industry's Wheel," is a Nova Scotian, and while we know him to be quite proud of his being Canadian-born, we rather incline to the belief that the provincial feature of his birth is just as he would have wished it. That he has recognized the need for broadening his outlook and enlarging his experience, will, however, be apparent from the disciplinary schooling—educational, military and business, to which he has applied himself, also from his procuring, by travel, first-hand information concerning his own and other lands. He was born at Dartmouth, N.S., December 21, 1876, the eldest son of the late John F. Stairs and Charlotte (Fogo) Stairs, both of whom were Canadian-born. He was educated at private and public schools in Halifax, N.S.; attended Trinity College School, Port Hope, Ont.; and graduated from the Royal Military College, Kingston, Ont., in 1907, winning the non-commissioned officers' Sword of Honor for exemplary conduct and military discipline.

In the same year he became connected with the Nova Scotia Steel & Coal Co. in the capacity of surveyor and draughtsman. From 1899 until 1901 he was draughtsman on construction work with the American Steel Hoop Co., resigning in the latter year to become night superintendent of the 10-inch and 16-inch Morgan merchant mills of the Duquesne Works of the Carnegie Steel Co. In 1902 he became chief draughtsman with E. L. McGary, consulting engineer, in which capacity he had charge of the construction of an open-hearth steel plant

JAMES ALFRED STAIRS.

and rolling mills for the Sharon Steel Hoop Co., and a manufacturing plant for the Standard Scale Co., at Beaver Falls, Pa. Following this, he joined the staff of the Lackawanna Steel Co., Buffalo, N.Y., as inspector for chief engineer during the construction of an open-hearth steel plant, a 32-inch slabbing mill, and a 48-inch universal plate mill, with their accessories of boilers, gas producers, etc.

Resigning this appointment in 1904, Mr. Stairs returned to his native province and re-entered the employ of the Nova Scotia Steel & Coal Co. as assistant superintendent of their rolling mills at Trenton, near New Glasgow, being later acting superintendent. In 1909, he associated himself with D. P. Brown in the organization of the Brown Machine Co., with a view to carrying on a general engineering and foundry business. Four years later the Eastern Steel Co. was formed, the Brown Machine Co., and the Bailey-Underwood Co., manufacturers of agricultural implements, amalgamating under that title. Like most other metal-working plants in Canada during the past two years or more, the Eastern Steel Co. is for the most part engaged on munitions production, an output of 600 18-pdr. shrapnel and 250 4.5-inch H.E. shell per day being steadily maintained. In the adaptation of the plant to the successful manufacture of munitions, the experience of our "spoke" acquired in other directions, combined with his endowment of a clear appreciation of the fitness of things mechanical, were given unlimited opportunity.

Among the more important construction contracts on which Mr. Stairs has had direct charge, since 1909, may be noted the following:—Bank head at Albion Mine, and boiler house, Allan Shaft, Acadia Coal Co., Stellarton, N.S.; erection at Port au Port, Nfld., of loading plant for storing limestone for Dominion Iron & Steel Co.; fabrication and erection of steelwork for buildings of Acadia Sugar Refining Co., Dartmouth, N.S., all of the steel being fabricated in temporary shop on the site. A number of the columns on this job were 55 feet high and weighed 5½ tons each, while many of the girders weighed 8 tons each. The whole contract was completed between the months of May and November, a total of some 1,600 tons of material being handled.

Mr. Stairs is Conservative in politics and Presbyterian in religion. He holds the rank of Captain in 78th Battalion Canadian Militia; is past president, Nova Scotia Society of Engineers, and a member of Albion Lodge, A.F. & A. M. He is a strenuous advocate of protection and encouragement to both Canadian industries and to Canadian farmers. In 1906, he married Margaret E. Hillman, of Philadelphia, Pa., their home being in New Glasgow. In addition to travelling in the United States, he has made opportunity to visit Great Britain and France, thereby materially adding to his repertoire of men and things, and incidentally enlarging his usefulness as a citizen and manufacturing plant executive. In addition to his association with the Eastern Steel Co., he is director, Wm. Stairs, Son & Morrow, Ltd., Halifax, N.S.; director, Scotia Printers, Ltd., New Glasgow, N.S.; and president, Bedford Chambers, Ltd., Halifax, N.S.

"During 20 years' experience in different departments of steel plant work and constructional engineering," says Mr. Stairs, "I have found that the best way to accomplish anything is to first make up your mind that the proposition is not going to beat you; then neither let extra hours nor minor obstacles stand in the way. Persistence and self-confidence will pull a man out of any hole. Money may be lost through errors of judgment, but a reputation for having finished a job counts for as much as cash profit, as one can always get another job if health holds.

"The great problems to-day are handling men so as to develop a fighting spirit among them that will create enough initiative to clean up minor obstacles without appealing every time to the boss, and the ability of the latter to observe these men and reward them. Organization and control of a shop centres in the superintendent. A thoroughly efficient system of reports submitted daily is absolutely essential, as only by following up the information contained can the men be kept on the alert.

"Techincal education should be encouraged by all manufacturers, and technical papers be read closely, the advertisements as well as the editorial, as so many new and profitable devices are continually being offered, and should be taken advantage of.

"Every firm who can stand the expense should have instructors for their apprentices; in addition, apprentices should be paid to attend technical classes, where these are organized and are reasonably convenient."

COMPRESSED AIR IN RAILROAD SHOPS

COMPRESSED air, which was used before electricity as a transmitter of power, is used in practically every railroad shop in the country, and, besides being used, it is also much abused at many of these points. Compressed air has the possible advantage over electricity in that means of utilizing it can be manufactured cheaply and easily. It is largely owing to this fact that it has been developed for railroad shop and yard work. It has the same disadvantage, however, as using a cheap but inefficient motor: The first cost is low, but the consumption of power is high. This might not at first be thought a serious consideration, but a check of several shop power plants shows that, not deducting for the exhaust steam, the shop air compressor consumed over 38 per cent. of all the steam generated by the shop power plant. This is due to several causes:

1.—The use of compressed air has been developed for various classes of shops, so that each individual shop, round house, and yard that makes up a group of railroad shops has its air lines and air tools.

2.—Unlike an electric transmission system a compressed air system can have a large number of leaks without causing immediate trouble other than an increased load on the air compressor. Even with careful supervision over the pipe lines there are always leaky valves developing, valves carelessly left partially open, or leaky air hose left with the pressure on it, while the compressor runs on 24 hours in the day, compressing air to be wasted.

3.—As shop air lines are constantly being extended, it is not at all unusual for the feeders to be outgrown. This is a frequent cause of complaint, the complaint usually being that the compressor is too small, whereas, in this case, the compressor is not to blame. In planning a compressed air system, it is most important to get the mains and the reservoirs large enough not only to take care of the present, but to provide for future growth.

4.—As a usual thing, the smaller shops are dependent on one air compressor alone, which require that this compressor run 24 hours in the day and 365 days in the year. The result is that the engineer postpones any heavy repairs on the air compressor as long as he possibly can with a corresponding increase in the coal bill for which the air compressor is often not suspected. All in all, the air compressor and the compressed air equipment are very important and useful parts of a shop's equipment, but unless great care is taken they are much less efficient than they should be.

Steam and Electric Drive

Where a steam plant is necessary, regardless of whether a steam-driven compressor is installed or not, especially when the greater part of the exhaust steam is needed for heating during a portion of the year, and further when a steam-driven compressor can be installed in the power plant, and operated without the need of an additional engineer, an electrically-driven compressor cannot show much, if any, economy over the steam-driven machine. The advantage of the electrically-driven compressor is that it can be located near the point where the air is to be used, consequently long pipe lines can be avoided. With the electric compressor, as well as with the steam-driven compressor, a certain amount of power is consumed whenever the machine is running idle. A recent check of a motor-driven, two-stage compressor of about 500 cubic feet per minute capacity showed that the electrical energy used, while the equipment was running unloaded, was 17 per cent. of the amount used when compressing air to 110 pounds pressure. This loss may be avoided, especially with the smaller sized compressor, by installing an automatic starter for the motor, controlled by a pressure regulator. The advisability of such an installation depends largely on whether there are fairly long periods when the compressor may be shut down if equipped in this manner. If the compressor is required to start every few minutes, it would be more advisable to install an unloading device on the compressor and permit it to run constantly at full speed.

With a plant using one or more electrically-driven compressors, the question of whether the equipment shall be located at one point or distributed at two or more points depends on the first cost of the installation, the cost of transmitting the air and the electricity to the desired points, the diversity of the load and the cost of attendance. As these items vary for each plant considered, it is impossible to lay down a definite rule. In the case of yards located at considerable distances from the steam power plant, it would be cheaper to transmit the electricity to the desired point than to transmit compressed air with the same percentage of loss. On the other hand, with a fairly compact shop plant, the additional cost of a pipe line designed to transmit the air efficiently from one point would be counterbalanced by the advantage of having all of the compressor equipment under one supervision. The importance of keeping all unused air lines shut off and of keeping all lines in first class condition may be emphasized by taking a concrete example.

Air Lines Maintenance

Assume that air compressed to 100 pounds pressure at a certain shop is costing four cents per thousand cubic feet of free air. A hole 1-16 inch in diameter in the pipe line would permit a leak of 6.45 cubic feet of air per minute, which would cost 37 cents per day of 24 hours, or $135 per year. The following figures are the results of a test for air leakage, which was run at the shop and terminal plant of a railroad entering Chicago. At the time the test was run there were no machines in operation, therefore, the total leakage was due to leaks in the air line. This line was originally installed about 25 years ago, but has been continually repaired and added to since then. After the system was filled to a gauge pressure of 100 pounds per square inch, the compressor was stopped. When the gauge pressure had reached 40 pounds the time was noted. The calculations showed a leakage of 9.446 cubic feet of free air in 55 minutes, or 171.7 cubic feet per minute. The steam used per cubic foot of free air was shown by a previous test to be .1306 pounds, and the steam used in pumping leaking air amounted to 1,344 pounds per hour. The totals were:

Cost per hour of leaks ....$	0.224
Cose per day (24 hours) ..	5.38
Cost per month	161.40
Cost per year	1936.80

Add 10 per cent. for machine leaks when shop is in full operation, the amount is $2,905.20.—From a committee report. Association of Railway Electrical Engineers, Chicago.

A DEPARTMENT of glass technology at the University of Sheffield has been organized with the financial support of the Advisory Committee of the Privy Council for Industrial Research, of the Ministry of Munitions, and of the glass manufacturers of South Yorkshire. An actual glass factory will be established, in which operations will be done on a large, semi-commercial scale. The model factory will be equipped with pot furnaces and a small tank furnace and a series of experimental furnaces, including a number of electrically-heated ones and some heated by gas.

PROGRESS IN NEW EQUIPMENT

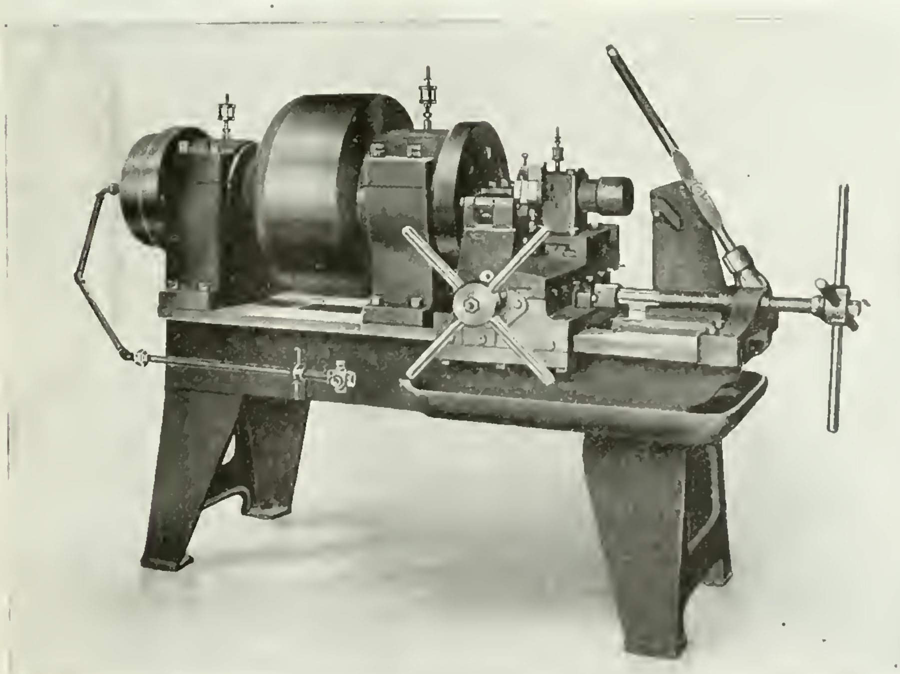
A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

RAPID PRODUCTION SHELL LATHE

A RECENT addition to the ranks of shell making equipment is the machine shown in the accompanying illustration, which, while resembling in general appearance a single purpose machine, is so designed that it can be adapted to almost all of the numerous operations required on a shell. The bed is of high grade iron, 18 in. wide constructed to provide the maximum rigidity under the heaviest strains. The headstock is composed of two separate housings firmly bolted to the bed. The front bearing has a diameter of 9½-in. and a length of 7-in., while the rear one is 6-in. dia. and 7-in. long. These bearings are of high-grade babbit and are amply provided with suitable oiling devices. The spindle is of semi-steel and forms the outer portion of the air operated chuck; the split collet being located in the nose of the spindle, and the operating cylinder at the rear. With the chuck contained in the spindle and the exceptionally large bearings, any excess overhang is eliminated, thus permitting heavier cuts and greater stability.

The driving pulley is 21 inches in diameter, 8-inch face and fitted with a heavy bronze bushing with efficient oiling facilities. The clutch is of the cone type fitted with wooden friction blocks operated on the inner surface of the pulley rim. This clutch is controlled by air with the same movement that operates the chuck, but special provision is provided to allow for any variation in shell diameter, so that the driving power is always constant. The carriage is of semi-steel with a length of 24 inches and fitted with a special long slide rest for the various tool blocks. The cut shows the machine tooled for waving and grooving but other tool blocks are provided for the various operations.

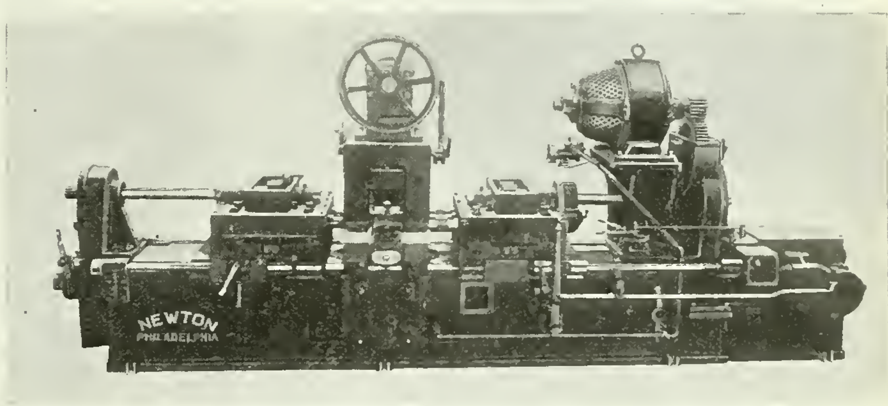
The Montreal General Tool Company are the designers and builders of these machines.



RAPID PRODUCTION SHELL LATHE.

FIVE SPINDLE HORIZONTAL RAIL DRILLING MACHINE

THE accompanying illustration shows a newly developed drilling machine having five opposed spindles arranged to permit of drilling holes with close centres in rails, and still retaining a powerful drive.



FIVE SPINDLE HORIZONTAL RAIL DRILLING MACHINE.

The range of adjustment on the three spindle head is from 4 in. to 10½ in. between centres; the central spindle being fixed, the two outside spindles being adjustable from the operating side by means of a screw. On the two spindle head, the adjustment of the spindles range from 4 in. to 19 in. between centres. Either spindle on the two spindle head can be brought within 1 in. of the centre line of the central or fixed spindle on the three spindle head, thus providing a possibility of drilling holes within 1 in. centre distance.

Maximum distance between ends of spindles is 26 in., length of feed motion to each spindle 12 in. which will permit of removing a full length drill without disturbing the setting of the rail. Spindle gears are all of heat treated alloy steel, the various other parts being made of material best suited for the purpose.

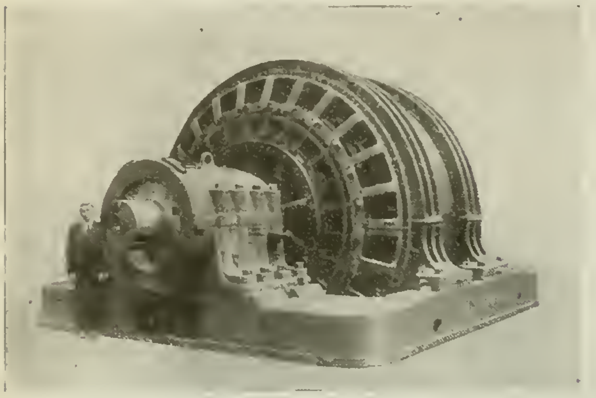
Spindle saddles have full bearing on the base with strap and taper shoes, to compensate for wear, and are operated from a common pair of feed screws with right and left hand threads so that the right and left hand operate simultaneously.

Spindle heads have four changes of feed with rapid power traverse in both directions. Saddles are supplied with adjustable automatic stop to the feed motion with rapid power return having a safety limit to prevent jamming at either end of the saddle movement.

Machine has an adjustable elevating table to take care of the different size rails and is provided with an air controlled clamp, and is driven by a 15 h.p. motor having a speed range of 400 to 1200 R.P.M. The Newton Machine Tool Works, Philadelphia, are the builders of this machine.

LARGE ELECTRIC MOTOR

MODERN developments in electrical power equipment are aptly illustrated by the accompanying photograph of what is said to be both the largest and most



LARGE ELECTRIC MOTOR.

powerful electric motor ever built. The engraving shows it in the shops of the builders, the Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa. It is designed for driving a two-high 35 in. reversing blooming mill which reverses for every pass, i.e. every time metal goes through the rolls.

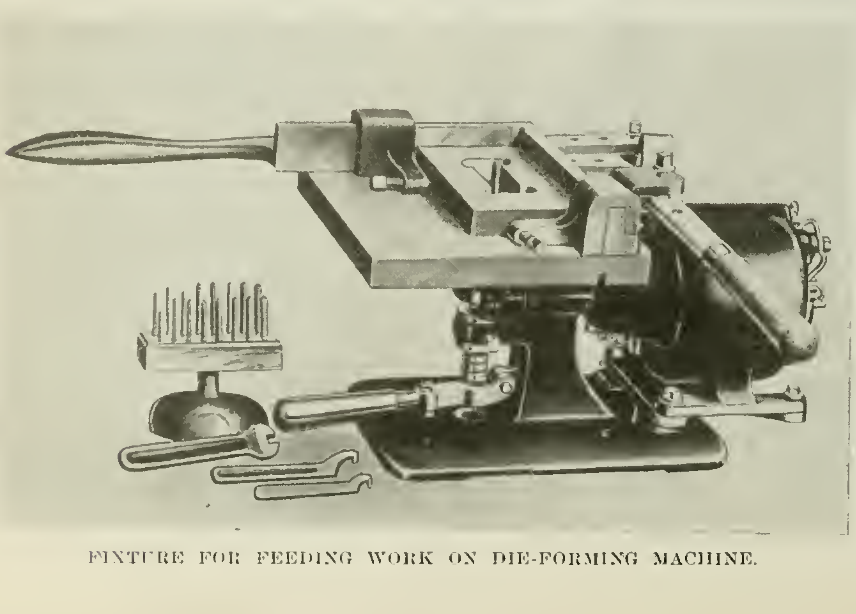
The horse power developed is 15,000 and reversals can be made from full speed to full speed in about 2 seconds, 19 or 20 passes being made in 2 minutes under regular working conditions. The total weight of the complete motor is over 250 tons, the rotating part alone weighing 100 tons. The overall height is 20 ft., while the shaft diameter exceeds 24 ins.

FEEDING FIXTURE FOR DIE FORMING MACHINE

A UNIVERSAL pivoted feeding mechanism is illustrated herewith which has been developed by the makers of the Anderson die forming machine for facilitating the working of that machine on which it is shown in position. This fixture provides complete control of the die while being operated on by the cutter.

The die rests upon the table or platen, and is secured to an angle bracket by a pair of adjustable dogs or clamps, the bracket also resting on the platen, and being pivotally connected to a lever located at the rear. This lever has a series of holes placed about an inch apart, which allow the pivotal point to be conveniently located with regard to the necessary movement of the die around the cutter. This lever is fulcrumed on an adjustable arm attached to one edge of the platen, so that a combined adjustment of the lever and arm enable any portion of the die to be fed or guided so as to finish practically any outline without the operator touching the die with his hands.

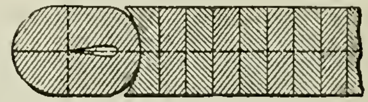
When ordinary hand-feeding is desired, the fixture can be removed in a few seconds. It is now furnished as regular equipment by the Anderson Die Machine Co., Bridgeport, Conn.



FIXTURE FOR FEEDING WORK ON DIE-FORMING MACHINE.

PROTECTION-EDGE LAMINATED BELTING

BELTS on a planing machine are shifted from pulley to pulley every minute, sometimes every few seconds. There is therefore great wear on the edges, due to the friction of the belt forks, and the edges may be worn out while the centre of the belt is still in good condition. The result is that extensive repairs are required, involving delay and expense. To prevent this occurrence, John Tullis & Son, St. Ann's Leather Works, Glasgow, Scotland, have just introduced a protection-edge laminated belt, in which a special wearing piece is introduced on each edge. The belt itself, as per illustration, is made of laminae, ½ in. by 3-16 in., set on edge and sewn right through from edge to edge of the belt, the stitches lying on the neutral axis. The outer lamina on each side is hollowed on its outer face, as shown, and the protection strip is laid in this hollow. This strip is originally 1 in. wide by 3-16 in. thick, and it is laid against the edge of the belt like the flange against the web of an I beam. The stitches pass first through the protection strip, then through all the laminae, and finally through the second protection strip, binding them all firmly together. When the sewing is complete the protection



PROTECTION-EDGE LAMINATED BELTING.

strip is bent into U-form, as shown, and the two limbs of the U are sewn tightly together, a layer of cement being interposed between them. The protection strip thus becomes flush with both surfaces of the belt, and its outer edge is finally rounded off.

We understand that the belt answers immediately to the touch of the belt-fork and changes pulleys instantly, effecting a marked saving of time. In a recent trial a saving of nine hours per week was registered. As there is no cross-joint, since the joints in the various laminae occur at different places, there is no jolt or jar as the belt passes over the pulley.

MACHINIST'S SCREW DRIVER

A MACHINIST'S screw driver of robust construction has been put on the market by the Peck, Stow & Wilcox Co., Cleveland, O., a feature of which is a special square shank which permits the use of a wrench in turning heavy screws,

SOLID BAR MACHINISTS' SCREWDRIVER

enabling sufficient pressure to be brought to move the most stubborn screw.

This No. 1 size screw driver, marketed under the name of Pexto, is of "Solbar" construction, a solid bar of steel forming both shank and handle, and will withstand rough usage under all conditions.

Marvels of Creation.—A Scotch preacher had been abroad and when he came back he was preaching to his congregation on the marvels he had seen. He wound up with this: "And the same Creator who made the vast ocean, made the dewdrop. The same Creator who made the mountains made the pebble. Yes, and that same Creator who made me made a daisy!"

Europe has about three and one-half times the telegraph traffic, nearly twice the first-class mail traffic, but only two-thirds the telephone traffic of the United States.

FUTURE ASPECTS OF SKILLED LABOR.

ONE of the principal handicaps which manufacturers are likely to encounter in this country, in the generally expected struggle for after-war trade, will be the obtaining of a supply of suitably trained labor. References to the lack of graduate apprentices recur at increasingly frequent intervals, generally accompanied by expressions of disappointment regarding the incompetence of such help as offers itself where trained journeymen were formerly available. Observers, both in Britain and America are noting closely the present tendencies of the situation, and where possible are exerting personal influence to the end that the employee's interests in obtaining a proper training are too closely identified with the employer's to permit the latter to ignore the facts of the case indefinitely.

A few mechanics are born, some are trained, but a large proportion are the creatures of circumstances, who started in a machine shop as boys glad to get rid of school studies and brain work of any description. Perhaps the machine shop was the only local opportunity; had it been a packing-house or a cheese factory, they would have started there for just the same reasons. Such youths seldom remain long enough or work seriously enough to imbibe any ideas of the trade's requirements; they may ultimately manage to read a micrometer and yet be unable to work a problem in decimal fractions, and no one cares, at the time. In after years the same youth may make costly errors in his work through careless reading of dimensions on drawings while his employer anathematizes machinists generally.

These conditions have been common in the past—most of our readers are probably able to recall such individuals and occurrences—and all of them have doubtless agreed that when all was said and done, the employers have themselves to blame, because they don't want to spend their own time or money training help for the ultimate benefit of other firms, and when the majority of employers view the situation thus, no remedy seems applicable.

At the present moment, too much importance is attached to the seeming ease with which munition workers have adapted themselves to work altogether foreign to many of them. The success attending the employment of women operators in several instances has also helped in developing a deprecatory attitude toward the trade of the machinist. Such views are, however, based on temporary conditions, and are more frequently off-hand and superficial rather than the mature verdict of extended observations.

Nothing but a return to ordinary commercial work will bring about the previous state of affairs. The repetitive feature of shell production will not be present, and the efforts of this country to build up a foreign trade will involve for some time a variety of manufacture, throughout the country generally, and in many shops in particular, which will create a real demand for the all-round machinist, and it is in their efforts to anticipate this demand that manufacturers, who are laying plans for the future, have opportunity for displaying a degree of prescience, indicative of their ability to play a larger part in the future upbuilding of our industries.

Very few of our firms are in a position to operate training schools for apprentices, and the feasibility of co-operation among employers is suggested thus by a writer in a contemporary: "Why not get together within the industry and organize what will be frankly trade schools, owned and operated by the manufacturers through the medium of stock companies where boys shall be offered opportunities that they cannot afford to pass by?" This remark is quoted without any disparagement of the work being done in technical schools; attendance at such institutions does not always mean that the student will join the ranks of skilled mechanics—frequently he is induced to leave and enter the employ of some firm which fails to realize that it is to his own and the industry's ultimate loss.

The equipment and instruction given in a jointly owned school could be of a varied yet thorough nature which while in line with the general requirements of the student's employers would insure his ability to tackle any work not absolutely specialized.

Out of the large number of present operators, quite a few bright individuals are available who might well form the nucleus of a later addition to the ranks of trained machinists, an asset of considerable value to the trade, employers, and nation.

THE PIG-IRON SITUATION

THE iron and steel market continues to be affected by the international situation and the steel trade in Canada is being influenced in sympathy with conditions in the United States. Prior to the severance of diplomatic relations between the United States and Germany, the market was tense and unsettled. However, as soon as the decision was announced the situation cleared, and notwithstanding the diplomatic break, the market exhibited considerable activity, particularly in pig-iron, with the result that prices advanced. The advance in prices of pig-iron will, of course, be reflected in finished materials. The coke situation is serious and deliveries are very bad, owing to the shortage of cars and motive power, although every effort is being made to bring about the much desired relief. A large number of United States Steel Corporation furnaces are out of blast, while those in Canada and the Buffalo, N.Y., district, which depend on Connelsville coke, are at least badly handicapped, some as a matter of fact being out of blast. There is consequently a serious shortage of pig-iron, with little prospect of relief in the meantime. While foundry iron is being quoted around \$35 to \$36 Valley and Buffalo furnaces, there is practically none to be had. At this price, pig-iron laid down at Toronto would be \$42.00 to \$43.00 per ton. Indications point to a more serious shortage of pig-iron than has yet existed, and, should this condition arise, \$50.00 pig-iron in Toronto may be looked for.

The General Market Condition and Tendency

ALTHOUGH there has been no further development in the strained relations between the United States and Germany, the possibility of war between these countries and its effect upon Canadian trade is still the main topic of discussion, particularly in manufacturing circles. Whether importations into Canada would be affected to any appreciable extent is a matter of conjecture, yet it is believed in some quarters that the situation would not be greatly changed. The severe weather has helped materially in further restricting the movement of cars on the railways and the situation is more acute than ever. In this district foundries are closing down owing to shortage of coke, and for the same reason furnaces are operating at reduced capacity. This, in turn, is adversely affecting mill operations, resulting in reduced output of steel. In this respect the situation is particularly serious, as the production of munitions is liable to be affected unless conditions improve at an early date. Steel prices continue very firm, advances in tubes, bolts and nuts having been registered during the week, while higher prices on other steel products may be looked for in the near future. On all raw material, the general trend of prices is upward, and this will be reflected in prices of finished goods. Prices of ingot metals have been well maintained, with advances in lead and antimony. The situation in the metal markets, however, will be more or less unsettled until the relations between the United States and Germany are definitely settled one way or another. Scrap prices are firm, with an upward tendency for most metals. Prices of machine tools continue to advance steadily. Business has, however, been quiet, although outlook is favorable.

Montreal, Que., Feb. 12.—Industrial conditions are now at a stage when it is next to impossible to define the actual situation. Actual hostilities between the United States and Germany are still a matter of the future, but should it so happen that circumstances are unfortunate enough to bring about war the effect on Canada may call for strict measures to cope with the changed conditions. The severity of the weather and traffic congestion on the railroads is seriously affecting the general situation, manufacturers experiencing great difficulty in obtaining much needed material.

Steel.

Owing to the dependency of Canada on American products, early developments may create a serious situation in this country and steel production here would require to be stimulated to meet the existing requirements. The demand for steel forging billets has been so insistent that Pittsburg quotations have advanced $5 per ton, the price being now $85 per ton. Production has been somewhat curtailed owing to lack of ferro-alloys, the domestic supply being scarce and shipments from abroad being delayed through shipping regulations. Ferro-silicon is now quoted at $200 and ferro-manganese as high as $250 per ton. Recent demand for plates has been light, but this is largely due to the fact that many mills will not take business owing to their heavy future bookings. Early future conditions may demand increased production of this class of steel, with the result that other output must suffer. The demand for wire products has not increased to any great extent, but the spring requirements, together with pending developments may create increased demand and also stiffer prices. Inquiries for black sheets continue to tax the productive powers of the mills and a recent advance of $5 per ton has been placed on Pittsburg quotations, the current price being $5.25 per hundred. The local situation is much affected by freight congestion, weather conditions making it very difficult to receive delivery of material. Should a crisis be reached on the other side of the line dealers here anticipate a much more serious condition than that at present. Prices here are generally firm, those affected this week being plates, which show an advance of about 10 per cent. Plates 1/4 to 1/2 inch are $6; heads, $6.35, and tank plates 3-16 inch, $6.10 per hundred. Other quotations are firm with a higher undertone.

Metals.

General condiions continue very firm with quotations stronger, the feature of the week being the further advance of antimony. The tension of the United States political situation, together with transportation difficulties, tends to maintain a strong but unsettled market. Copper is firm and higher. Tin is strong as a result of increased marine risks. Spelter is steady but uncertain. Lead is higher and scarce. Antimony is very strong, but early delivery may develop a weaker tendency. Aluminum is very firm but unchanged.

Copper.—The ever-present possibility of uncertain developments tends to keep the market in a nervous and unsettled condition. Circumstances at the present time are not a reliable guide to buyers of metal, as international relations are such that the market might move forward or backward by hourly developments. Another factor that tends to add strength to the situation is the extreme difficulty in getting delivery. Many consumers of copper are forced to obtain shipments by express. Prices continue to advance both in London and New York, the latter quoting the nominal price of 33½c. for prime lake, 34½c. for electrolytic, and 30½c. for castings; these quotations show an advance of 1½c. on the two former and one cent on castings. Dealers here are quoting last week's prices, but anticipate an early advance.

Tin.—Continued activity on the part of enemy submarines and the consequent danger to shipment of metal from abroad is maintaining a very strong market, which is reflected in the further advance of prices. Buyers in many instances are compelled to take the risk of arrival, and this makes consumers rather cautious in contracting for requirements. English markets are higher and New York has advanced 3½c. over last week, the nominal quotation being 55c. per lb. Prices here are unchanged and nominal at 56c. per lb.

Spelter.—The lull that followed the activity of a couple of weeks ago has been partly dispelled and business is slightly brisker than last week, but conditions are such that a movement on the part of buyers would strengthen the market, while an adverse effect would result should sellers show an active interest. The prevailing strength is more related to the uncertainty of early future possibilities than that of actual present conditions. New York is one cent stronger than last week, the quotation being 10⅝c. per lb. The market here is firm at 15c.

Lead.—Railroad difficulties and uncertain delivery have resulted in further strength in the lead situation. Little relief is expected for some time. Added to this, the apparent scarcity has had much to do with recent advances. The current trust price is 8½c., and independents are asking 9¼c., these quotations being an advance over last week of ½c. and ¾c. respectively. The local situation is active at last week's quotation of 11c., but with a stronger undertone.

Antimony.—Following a brisk inquiry for spot metal on the part of certain munition manufacturers the price of antimony was subjected to another sharp advance. Metal for immediate delivery is extremely hard to get, but the supply in transit is expected to relieve the tension of the situation. The time of delivery, however, is so uncertain that the present market will likely be maintained until sellers become active, and it is anticipated that the near future might see a decline to a lower level. Reports from New York show an advance of 10c. over prices quoted last week, the current quotation being 35c. per lb. Dealers here report a heavy demand, on an advance of 12c. over last week, the price this week being 37c. per lb.

Machine Tools and Supplies.

The volume of business is not large, but the inquiry for single tools and small lots is sufficient to maintain a fair degree of activity in Canadian tool circles. American manufacturers and those plants recently employed on munitions are not taking the same interest in this field that was shown about a month ago. This is probably due to the unesttled conditions following the action of the U.S. government in breaking off relations with Germany. Should the situation become more critical and the republic be involved in hostilities, the manufacture of shells for possible needs may stimulate the machine tool industry to the point where it would be increasingly difficult to secure delivery of machinery to Canadian users. This would undoubtedly reflect favorably on manufacturers in this country as the demand for home machinery would be greatly increased.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

Scrap

The tendency of old metal is upward, but the market is somewhat disturbed owing to general conditions. Large consumers are light buyers, not covering their requirements for extended periods. New York quotations on copper wire and brass clippings are higher, also on composition turnings, but local dealers report unchanged conditions and prices.

Toronto, Ont., Feb. 15.—The shortage of coal dominates the industrial situation and there is no apparent relief in sight, notwithstanding the great efforts that have been made to improve conditions. A serious tie-up threatens our factories to say nothing of the inconvenience to the public at large. The shortage of coke is also serious and promises to develop into an actual famine if drastic steps are not taken at once to relieve the situation. The shortage is seriously restricting the operations of foundries and furnaces, which in the latter case will be reflected in a decreased production of steel.

Steel

Steel plants, in this section of the country particularly, are feeling the shortage of pig iron more than ever and the increase in cost of this material will be reflected in finished and semi-finished steel. The market continues very strong with a decided upward tendency in prices. The advance in tubes, in effect this week, is a direct result of conditions in the U.S. market, while higher prices on other materials may be looked for in the near future. The market is still overshadowed by the possibility of war being declared between United States and Germany. Consumers are anxious to get delivery on as much material as possible in case the U.S. Government should place orders for steel for war purposes. The demand on the mills for plates from shipyards is very heavy, the output being sold for the balance of the year. Prices of plates are very firm and will doubtless advance in the near future. Lapweld boiler tubes have advanced 10 per cent. All makers of iron and steel tubes are practically sold up for all of this year. An advance in bolts and nuts of approximately 6½ per cent. is now in effect.

Prices on black sheets are very firm with an upward tendency.. The demand is heavier than the mills can take care of, as production is being restricted because of the difficulty in getting fuel and raw materials. Sheet bars continue high in price with a possibility of further advances. On account of the situation in black sheets, prices of galvanized materials are holding firm.

The steel market in the U.S. is steady and firm notwithstanding the unsettled international situation. Whatever may result from the present strained relations between the United States and Germany there is little doubt but that steel prices will advance. Production is being curtailed on account of the transportation difficulties and cold weather. The coke shortage is more acute, shipments of Connellsville coke being only about half of the amount required. Chicago warehouse prices have advanced and quotations are now as follows. Steel bars 3.90c; steel bars 2-in. and up, 4.40c; structural shapes 4c, and plates 4.75c. Pittsburg steel bars are unchanged at 3.25c, and shapes at 3.25c, but tank plates are higher at 4.75c. The unfilled orders of the U.S. Steel Corporation on Jan. 31 were 11,474,504 tons, being a decrease of 73,232 tons compared with Dec. 31.

Pig Iron

Production of pig iron continues to decline owing to the coke shortage which is getting more acute. The cold weather at the ovens has curtailed operations and the production of coke has been practically cut in half. Railway conditions are no better, seriously restricting the movement of coke to the furnaces and thereby curtailing output. Many foundries are working at reduced capacity and in some cases have shut down until the situation improves. Some pig iron is being imported from the United States, although not nearly as much as is required. Price continues high, being about $35 Buffalo or Valley furnace, which would be around $43 laid down in Toronto. Canadian pig iron continues off the market and no quotations are being issued.

Scrap

Prices of old material are generally firm but there have been no important changes made during the week. The curtailment of pig iron production is causing the mills to use more scrap; this will tend to advance prices. There is a fair demand for steel turnings and borings but supplies are coming to hand in good volume. All copper and brass scraps are firm in sympathy with new metal.

Machine Tools

There is no change in the situation in the machine tool market, although the outlook is at the present time rather unsettled on account of international complications. Prices of machine tools in the U.S. continue to advance, affecting several types of machines. Power hammers have advanced 10 per cent; planers, boring mills, and radial drills are from 10 to 20 per cent. higher, while drills are 5 per cent. higher. Deliveries are slower particularly on milling machines, shapers and lathes.

Supplies

Business continues active and prices are still advancing owing to the increase in cost of practically all raw materials. The leather market is very firm and higher prices on belting are looked for. Cut lace leather and side lace leather have advanced about 5c per pound, being now quoted at $1.60 and $1.40 respectively. Stillson and Trimo wrenches have advanced 10 per cent. Gasoline is very firm but unchanged meantime, although the falling off in the production of crude oil and continued heavy consumption of gasoline may result in higher prices. Coal oil has however advanced 1c a gallon.

Metals

The possibility of the breach widening between the U.S. and Germany has been reflected in the metal markets during the week. The likelihood of increased demand for war metals has had a tendency to hold prices firm, but they are in many cases entirely nominal. Lead and antimony have advanced, otherwise prices are unchanged. Busi-

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

St. Catharines, Ont.—The St. Catharines Brass Works, Ltd., is building a foundry.

Winnipeg, Man.—The Swift Canadian Co., are considering the erection of an abattoir, to cost $3,000,000.

Pembroke, Ont.—The Pembroke Machinery Co., will at an early date erect a machine shop to cost $12,000.

Vancouver, B.C.—John Coughlan & Sons, propose building a machine shop at an approximate cost of $10,000.

Toronto, Ont.—The Wm. Davies Co. will erect a frame and iron bridge between storehouses at 521 Front street, at a cost of $2,500.

Hull, Que.—The Hull Iron & Steel Foundries, Ltd., propose to make additions to its plant which it is reported will cost $500,000.

Hamilton, Ont.—Construction work has been started on the erection of an addition to the plant of the Canadian Shovel & Tool Co.

Toronto, Ont.—The Deyo Macey Engine Co., Binghampton, N.Y., will establish a plant in Toronto for the manufacture of gas engines.

Sarnia, Ont.—Large additions will be made to the plant of the Mueller Mfg. Co., and a considerable quantity of new machinery will be installed.

Windsor, Ont.—Fire on Feb. 7 damaged the Kelsey Wheel Co.'s. plant, the loss being estimated at $5,000 which is fully covered by insurance.

Hamilton, Ont.—The Standard Underground Cable Co., are completing the construction of an extension to their plant which will cost about $30,000.

Tecumseh, Ont.—The Eau Claire Waterworks Co., are in the market for two centrifugal pumps and motors. R. W. Code, Windsor, Ont., is the engineer.

Hamilton, Ont.—The Canadian-Desmond-Stephen Mfg. Co., Urbana, Ohio, is making preparations for the erection of a plant here for the manufacture of steam ejectors, etc.

Sherbrooke, Que.—Fire on Feb. 8, damaged the plant of the Mackinnon, Holmes Co., steel manufacturers, here, to the extent of about $30,000. The loss is covered by insurance.

Port Arthur, Ont.—It is understood that the Port Arthur Pulp & Paper Co., will not build a mill here as was originally intended. It is probable that the mill will be located in the Nipigon district.

Gravenhurst, Ont.—The foundry and machine shop of the E. Long Manufacturing Co. of this town was destroyed by fire on Feb. 6. The plant was valued at about $20,000, with insurance of $10,000.

Amherstburg, Ont.—It is reported that the Semet-Solvay Co. may proceed with the construction of a chemical plant here. It is understood that G. S. Rutherford of Hutchinson, Kan., will be in charge of the work.

London, Ont.—The United Metal Products Co., recently formed by local capital has taken over the factory building formerly occupied by the Jose Caste Cigar Co., on King street and will manufacture munition parts.

Welland, Ont.—The Canadian Steel Foundries, Ltd., has commenced the erection of an addition to its plant which will double the present capacity. The total improvements now under way, including machinery, will cost $500,000.

London, Ont.—The London & Port Stanley Railway Commission has decided to purchase a motor freight car at a cost of $23,500, to assist in handling the increased traffic of the road. The purchase was recommended by General Manager J. E. Richards.

GENERAL MARKET CONDITIONS

(Continued from page 143.)

ness locally continues good and the outlook favorable.

Copper.—Although the position of copper continues to be a strong one the situation is unsettled in the U.S. owing to the accumulation of supplies at the seaboard and embargoes placed by many railways on account of congestion of traffic. Producers are sold up for the first half of this year and there is very little spot copper to be had. Prices continue nominal and unchanged at 38c per pound.

Tin.—The market is quiet but prices are unchanged and nominal. The market is dominated by the submarine situation and the fear that cargoes of tin may be lost is tending to hold prices firm. Local quotation unchanged at 58c per pound.

Spelter.—The market is quiet and unchanged with no particular feature to note; local price 13½c per pound.

Lead.—Local prices have advanced following the action of the "Trust" in quoting lead at 8.50c New York. The outside market however is still higher ranging from 8¾c to 9¼c New York. Scarcity of supplies is understood to be the reason for the higher prices. Lead has advanced 1c locally and is quoted at 11c per pound.

Antimony.—Although antimony would not be affected by submarine operations, prices continue to advance, but are entirely nominal. Antimony has advanced 9c and is quoted at 35c per pound.

Aluminum.—The market is dull with quotations unchanged at 68c per pound.

London, Ont.—The London Smelting & Refining Co., have purchased the old power house of the London and Lake Erie Railway at Chelsea Green, London, and has converted this into a plant for the smelting and refining of metal under the management of Geo. Trudell.

Ottawa, Ont.—Hon Robert Rogers announced last Thursday that the Norton-Griffith contract for the St. John harbor works, had been cancelled and a new contract was being prepared and tenders would be called immediately and work carried on as expeditiously as possible.

Toronto, Ont.—British Forgings, Ltd., have taken out a permit for the second section of the foundation work for the factory they are to erect at the foot of Cherry street. The cost of the second part of the work is set at $35,000, or $10,000 above the first.

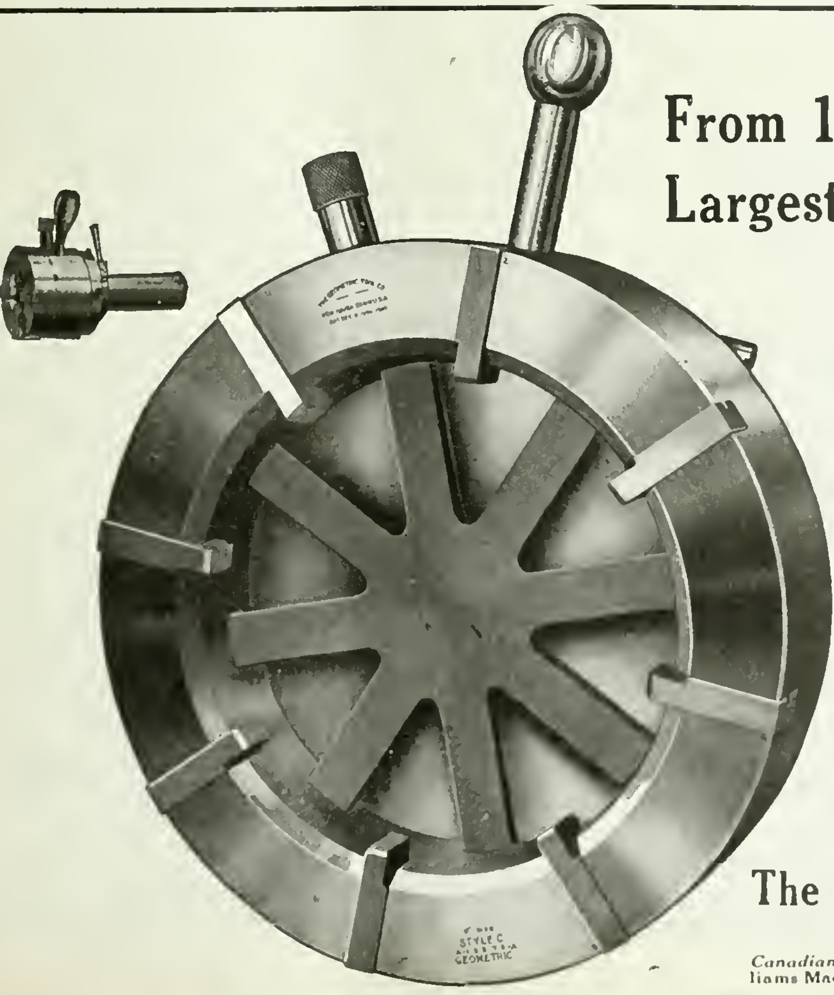
Toronto, Ont.—The City Architect has issued a permit for the erection of the first section and foundations of the new steel plant, which the Imperial Munitions Board are establishing in the Ashbridge's Bay district. The building and foundations are estimated to cost $200,000.

Port Mann, B.C.—Work on the new car plant of the C.N.R. at Port Mann is progressing satisfactorily, and should be in operation by the end of March. The plant will turn out five cars daily and when finished will do much towards relieving the car shortage which has become a serious problem.

Niagara Falls, Ont.—The Hydro-Electric Power Commission are buying a large quantity of contractors' plant in connection with their Chippewa Creek development here, including rubber belting, motors, cement, conveyors, electric hoists, derricks, locomotive cranes, small jaw crushers, concrete mixers and machinery, etc.

Newcastle, N.B.—The New Brunswick Sulphite Fibre Co., have just secured incorporation under Dominion charter, with a capitalization of $200,000. They have taken over the Millerton property and nearly all the necessary machinery for operating the pulp mill has been secured. The company expects to begin the manufacture of pulp in April.

London, Ont.—Beatty Bros. Ltd. of Fergus and London manufacturers of pumps, grain grinders, etc., have decided to locate their foundry at London in the Chelsea Green industrial district. This will be started immediately and will cost approximately $30,000. This development is only the beginning of plans for London where it is expected, they will before long employ between three hundred and four hundred hands. A large site was given free of cost to



Beatty Bros, through the Industrial Department.

Banff, B.C.—Dr. R. Harry Brett, of Banff, is one of the incorporators of a new company, capitalized at $20,000, that will develop some of the natural resources of the Alberta mountain country. The Alberta Electro-Chemicals, Ltd., has just been given a charter which empowers it to manufacture, buy, and sell chemicals, minerals and mine and forest products, with Banff as its head office. It is understood that the purpose of the new company is to manufacture carbide at Kananaskis Falls, near Banff. Advantage will be taken of the hydro-electric plant at the Falls for power purposes.

Vancouver, B.C.—It is announced that a large floating drydock is to be built here. The structure will be a 16,000-ton double-section dock, capable of handling a boat of 18,000 tons, wihch is the measure of maximum requirements on the Pacific to-day. The company is the Vancouver Dry Docks, Ltd. A ship-repair and shipbuilding plant is a part of the plan decided upon. Contracts for construction and machinery are being let, and the company announces that it will have the dock in operation within a year. There will be subsidy aid from the Governments of both the Dominion of Canada and the Province of British Columbia, on the ground that the dock will be a commercial and naval asset.

MUNICIPAL

Strathroy, Ont.—The Town Council contemplate purchasing a motor driven turbine pump.

Wolseley, Sask.—The Town Council are considering an extension to the light and power plant, to cost $9,000.

Strathroy, Ont.—Town Council has decided to purchase smoke helmets, cellar nozzles and other equipment for the fire department.

Toronto, Ont.—A bill will be submitted to the Provincial Legislature to empower the Board of Control to establish coal docks and storage at a total cost of $2,000,000.

Preston, Ont.—The Preston Car & Coach by-law, whereby the town will be asked to guarantee $75,000 worth of bonds, was put through and will go to the people on March 5th.

Preston, Ont.—The Town Council held a special session recently to consider the recommendation of the Board of Trade that a by-law be submitted to the ratepayers asking them to endorse a loan or a bond guarantee of $75,000 to the Preston Car & Coach Co.

Wiarton, Ont.—The Council is considering a proposition for electric light and power from the Hydro-Electric Commission. It is proposed to extend the hydro lines from Owen Sound and get current from Eugenia. Later it is proposed to develop power on the Saugeen River.

Edmonton, Alta.—Surplus machinery to the present estimated value of about $2500 is in the hands of the streets department, and will probably be offered for sale. The list of seventeen machines includes one gasoline road roller, two street sprinklers, four horse sweepers, two road graders, one mud scraper, one steam roller, and one automobile.

Peterborough, Ont.—The City Council will make certain recommendations to the Hydro Commission for extensions and improvements to both the street railway and the gas plant. It is understood that the Hydro engineers have already begun an estimation of the cost of certain extensions to the street railway which may materialize this year.

Preston, Ont.—The Town Council has authorized that the following supplies be purchased; 500 feet hose; 100 feet $\frac{5}{8}$ in. hemp rope; 1 peerless hose clamp; 2 shutoffs for hydrants; 1 shutoff tap $1\frac{1}{8}$ in. to replace a screw tip; 2 small nozzles $1\frac{1}{4}$ in., 2 in. tips, 1 basement nozzle; 1 smoke helmet; 2 life belts and detachable ladder straps; 2 dozen washers for hose couplings; half dozen hose couplings; 2 dozen brass bands for hose couplings; half dozen hose straps for ladders; first aid kit; springs for storm doors.

GENERAL

Hamilton, Ont.—The Shipman, Halton Knitting Co., are making preparations for the construction of a new factory.

Winnipeg, Man.—The Richardson Grain Separator Co., of Minneapolis, propose erecting a plant here in the spring.

London, Ont.—The Hobbs Mfg. Co., contemplate building a large extension to their local art glass etc., manufacturing plant.

Paris, Ont.—Penmans Ltd., will build an addition to their factory to cost about $30,000. Schultry Bros., of Brantford are the contractors.

Montreal, Que.—The Canadian Consolidated Rubber Co., will occupy the factory on Inspector Street to be shortly vacated by the Ames-Holden-McCready Co.

London, Ont.—The Quaker Oats Co., whose Canadian factory was recently burnt out at Peterboro, have purchased the plant of the Canadian Cereal and Flour Mills Co. here, and will carry out extensive developments there for the manufacture of their product.

Montreal, Que. — The Ames-Holden-McCready Co., boot and shoe manufacturers propose making extensive alterations and additions to their plant on Mount Royal Ave, East. Plans are ready and contracts will be let shortly. Considerable new machinery of the latest type will be installed. N. R. Feltes is general manager of the company.

Simcoe, Ont.—One of the worst fires here in many years occurred on Feb. 7, when the entire plant of the Simcoe Lithographing Co. was destroyed, involving the loss of something like $200,000 in valuable machinery and stock, both of which will be difficult to replace. It is understood that both the building and contents were insured. The officers of the company are endeavoring to secure new quarters in which to carry on their business temporarily.

TENDERS

Toronto, Ont.—Tenders addressed to the chairman of the Toronto Electric Commissioners will be received until March 28, for synchronous condensers. Specifications may be obtained at the office of the Purchasing Agent, 15 Wilton Ave., Toronto.

Winnipeg, Man.—Tenders will be received up to March 15, by R. D. Waugh, Chairman of Commissioners, Greater Winnipeg Water District, for the supply of approximately 12,500 feet of 48-in. and 1,300 feet of 60-in. cast iron pipes, together with specials and gate valves. Specifications on application to the offices of the District, 501 Tribune Building, Winnipeg.

Toronto, Ont.—Tenders will be received, addressed to the Chairman, Board of Control, City Hall, up to Feb. 27,, for the construction of a drainage system (wrought iron pipe), for the Rosedale bridge, Bloor Street Viaduct. Specifications and forms of tender may be obtained upon application at the Bloor Street Viaduct field office, 89 Castle Frank Road, Toronto.

Windsor, Ont.—Tenders will be received up to Feb. 28, 1917, for the construction of the superstruction of:—(a) One 70-foot clear span bridge. (b) One 80-foot clear span bridge. (c) Two 100-foot clear span bridges. Plans and specifications may be seen at the office of J. J. Newman, Davis Block, Windsor, Ont., or at the office of H. J. Rocheleau, Esq., Stoney Point, Ont.

Hamilton, Ont—Tenders will be received by the Board of Control up to March 5, for the supply of ordinary asd special castings, iron pipe, hydrants, valves, extension boxes. Lead pipe—Pig lead, rubber hose, rubber boots, road oil, lubricating oil, flux, fuel oil, coal oil, gasoline, brass work, including ordinary and special brass castings for water department, hardware, etc. Specifications may be obtained at the office of E. R. Gray, City Engineer.

PERSONAL

Brigden, Ont.—The hydro-electric by-law was carried by a large majority.

New Toronto, Ont.—A new Hydro-Electric sub-station is to be built, as the present one is not adequate to supply power to the number of new concerns locating here.

William Lyon Mackenzie, bridge engineer of the C.N.R., died at his home in Winnipeg on Feb. 8, at the age of 57 years. Mr. Mackenzie formerly was connected with the C.P.R. and Grand Trunk Railways.

E. L. Cousins, chief engineer of the Toronto Harbor Commission, has been elected president and J. R. W. Ambrose, chief engineer, Toronto Terminal Rail-engineering undertaking in Eastern Canada.

C. Kelso, for seventeen years in the employ of the Grand Trunk Railway System, and recently occupying the position of contract inspector in the motive power department, has been made master mechanic at the G.T.R., Stratfor Shops, succeeding Robert Patterson resigned.

TRADE GOSSIP

U.S. Steel Tonnage.—The unfilled orders of the United States Steel Corporation on January 31 last were 11,474,054 tons, a decrease of 73,232 tons compared with December 31.

The Canada Metal Co. held their annual convention at Toronto on Feb. 12 and 13. Salesmen from all over Canada attended the sessions which were presided over by W. G. Harris Jun.

Cheddite, Ltd., has had the name of the concern changed to that of Munitions & Metal Products, Ltd., with powers extended to manufacture explosives and munitions of all kinds.

Canadian Allis-Chambers Ltd., Toronto, have been awarded a contract for a Lidgewood cableway excavator system in connection with the Chippewa Creek development at Niagara Falls for the Ontario Hydro-Electric Commission.

Ralph D. Norton, Craig Street, Montreal has secured an exclusive agency for Canada for the John Illingworth, Steel Co., of Frankford, Pa. This concern has been established since 1855 and they make high grade crucible steel and also special open hearth steel.

Hadfield Offer Stands.—It is reported from Washington, D.C., that the contracts for more than $3,000,000 worth of armor-piercing shells let by the navy to Hadfields, Limited, the English concern, may be filled despite the British Government order that the company should not proceed with the work "so long as the exigencies of war continue."

Smokeless Powder Option. — Advices from New York state that the British Government has exercised an option on an additional 9,000,000 pounds of smokeless powder to be manufactured by the Aetna Explosives Co. This order, according to an officer of the company, is valued at $5,000,000, and is the second order for that quantity received from this source. A further option for an equal quantity is held by Great Britain and may be exercised before the end of July of this year.

Empire Trade Development.—Advices from London state that plans for the promotion of Empire Trade are developing rapidly. Already responses have been received from 28 governments to the movement for concerted co-operative action in the direction of having purchases made in every instance possible from British concerns. In an article reviewing the situation, the Glasgow *Herald* says:—

"For some time the Trade and Industry Committee of the Royal Colonial Institute has been engaged upon the work of encouraging the establishment of new industries in the British Empire with a view to giving a measure of confidence and security to capital to be embarked therein, as well as assisting the expansion of existing industries.

"As a result of a resolution the committee has been in communication with the Governments and Chambers of Commerce of the Dominions and colonies with a view to urging the necessity of making it obligatory on all Government and municipal bodies to purchase Empire-made goods, and to place all contracts as far as possible with British firms. Such action in the opinion of the committee would prove a strong factor in stimulating the establishment of new and the growth of existing industries, as well as consolidating inter-Empire trade.

C. G. Railway Finance.—Hon. Frank Cochrane stated in the House on Aug. 1, 1914, to Nov. 30, 1916, $9,920,249 had been expended on the construction of the Hudson Bay Railway. Mr. Cochrane said that the total receipts on Canadian Government railways during the financial year to Dec. 31, 1916, had been $18,658,956, and expenditures had been $18,342,733. He stated that 74 Intercolonial Railway engines had been sold to the National Transcontinental Railway, and that 32 I.R.C. engines were in use on the N.T.R. between Moncton and Winnipeg; that 33 I.R.C. passenger and 174 freight cars had been sold to the Transcontinental Railway. The Minister also said that 553,856 tons of coal had been purchased by the Canadian Government Railways in the United States last year.

Licenses for Ships Leaving Canada.—The situation caused by the German submarine blockade is being given consideration as far as the sailing of vessels of Canadian register are concerned by a ship licensing committee appointed by the Government to control Canadian steamship transportation. The committee is composed of Alec. Johnston, Deputy Minister of Marine; F. C. T. O'Hara, Deputy Minister of Trade and Commerce; Commissioner of Customs McDougald, and G. J. Desbarats, Deputy Minister of Naval Service. The committe has issued scores of licenses during the time it has been in control. No ship is allowed to leave Canada without such license and no license is given unless the committee is assured the vessel's trip will perform the most useful possible service to Canada and the Allies in view of the shortage of tonnage.

May Electrify T. & N. O. Railway.—J. L. Englehart, chairman of the T. & N. O. Railway Commission, said that the commission is preparing to electrify the line, and that during the past two years the road has been re-surveyed and plans prepared for this work. Electricity, he said, is in his opinion the future power of the province. Greater co-operation and big expenditure, he said, were the solution of the transportation question. Relief from the present congestion cannot, however, be hoped for during the progress of the war.

as conditions differ from all times in history. The Moose water powers, he said, though secluded, are readily accessible from all parts of Canada, and the fact that nitrate, which is used in the manufacture of explosives, is obtainable near this power supply, would suggest that the property is of Imperial importance, and should be developed immediately.

Port of Montreal.—The annual report of the Montreal Board of Trade showed the trade of Montreal to be in an excellent condition. The figures of the trade of the port of Montreal show an unprecedented increase, the total exports amounting to $382,741,463, which, compared with $155,685,953 in 1915, show an increase of $227,055,510, or 145 per cent. This increased volume of business is in the main due to orders placed in Canada for munitions and supplies for the Allies. The imports amounted to $194,924,348, as against $115,919,977 the previous year, an increase of $79,004,371, or 68 per cent., which would have been considered extraordinary at any other time although by comparison with the increase in exports it is inconspicuous. The customs receipts in Montreal amounted to $32,-915,686, an increase of eleven million dollars over 1915, and of nearly seven million dollars over the highest figure hitherto, $26,016,631 in 1913.

CONTRACTS

Port Arthur, Ont.—The Eastern Terminal Elevator Co. have awarded a contract for the construction of an elevator to Barnet & McQueen Co.

Port Arthur, Ont.—Contracts have been awarded to the Barnett-McQueen Co., for the new Eastern Terminals' 2,000,000-bushel elevator, which is to be constructed on the waterfront.

Niagara Falls, Ont.—In connection with the Chippewa Creek development contracts for rock drills and air compressor plants have been awarded to the Sullivan Machinery Co., Chicago.

Edmundston, N.B.—The Structural Steel Co., Montreal, have been awarded the steel contract in connection with the erection of a pulp and paper mill by Fraser, Limited. H. I. Ferguson, 200

Chatham, Ont.—The Imperial Munitions Board has awarded a contract for the construction of a large number of boxes for shells to the S. Hadley Lumber Co. The boxes will be used for shipping the 6-in. shells that are being manufactured by the Hayes Wheel Co.

MARINE

Victoria, B.C.—Yarrows, Ltd., of Esquimalt, have secured the contract for way Co., vice-president of the Engineers' Club, Toronto.

John George Macklin, civil engineer died near London England on Feb. 5. The deceased was born in England and came to Canada as a young man. He was associated with several prominent overhauling and repairing the Norwegian steamer Strinda. The vessel is now on her way to Vancouver from Vladivostok, under charter to the C.P.R.

INCORPORATIONS

The Gladstone Brush Mfg. Co. has been incorporated at Ottawa, with a capital of $50,000, to manufacture brushes of all kinds at Toronto. The incorporators are: Eldon Moir, Donald L. McDonald and Oral N. Birchard, all of Toronto.

T. F. Shurly Co., has been incorporated at Ottawa with a capital of $200,000 to manufacture knives, axes and edged tools of all kinds at St. Catherines, Ont. The incorporators are: Theodore F. Shurley, George B. Burson and Harry Short, all of St. Catharines, Ont.

The Port Arthur Pulp & Paper Co., has been incorporated at Toronto with a capital of $2,000,000 to manufacture pulp and paper. The head office will be at Port Arthur and the provisional directors are George H. Sedgwick, James Aitchison and Duncan HcArthur all of Toronto.

Standard Steel & Tempering Co., has been incorporated at Ottawa with a capital of $50,000 to construct and operate steel, iron, and brass plants, foundries and furnaces etc. The head office is at Montreal and the incorporators are S. H. R. Bush, B. Robinson and T. E. Durocher all of Montreal.

CATALOGUES

The Valve Twins is the title of a bulletin being distributed by the Homestead Valve Mfg. Co., Homestead, Pa., illustrating the "Hovalco-Homestead" blow-off combination valve.

Sub-Aqueous Lubrication, Bulletin issued by the Crew Levick Co., Philadelphia, Pa., dealing with sub-aqueous or under-water lubrication in hydro-electric stations with special reference to hydro-turbine lubrication at McCall's Ferry, Pa. The preparations described on "Turboglio" for under-water lubrication and "hydroglio" for governor lubrication.

Screw Machines Bulletin, dealing with the "Foster" No. 5 screw machine made by the Foster Machine Co., Elkhart, Ind. A description is given of the various parts and mechanisms accompanied by illustrations showing their general arrangement and also of the machine. Specifications are included of the two types, and complete set of standard tools for using on the machine are illustrated and described.

BOOK REVIEWS

Handbook of Machine Shop Electricity, by C. E. Clewell. 461 pages 6¾ x 4 in. Fully illustrated. Published by the McGraw Hill Book Co., Inc., New York City. Price $3.00 net. With a more general use of electricity in the machine shop, and which is increasing every day, a volume such as this will be of great assistance to the mechanic. It has been written from the point of view of the practical shop man and special attention has been paid to those subjects which apply in one way or another to particular uses of electric power in shop operations. The book was undertaken about two years ago at the suggestion of the editors of the *American Machinist* who desired to fill what they considered a need for a convenient electrical reference book adapted to the machine shop. The subject matter in the book is grouped under ten main headings, each being covered in a section. Each section has its own index of topics which are dealt with in alphabetical order. While there is also a list of contents at the end, and also a general index. The main headings cover the following subjects:—Abbreviations, terminology and units; Circuits; Costs; Communication and distant control; Current supply, generators and transformers; Electrochemical; Soldering and welding application; Heating and magnetic apparatus; Lamps and shop lighting; Measuring instruments and measurements; motors and applications. Each subject is dealt with in a complete and comprehensive manner, and the information contained in this volume will be valuable to the reader who will derive much practical benefit from a perusal of its pages. The book contains a large number of illustrations which help considerably in obtaining a clear and working understanding of the text.

Port Arthur, Ont.—At the plant of the Western Dry Dock & Shipbuilding Co., work is now started on two more ocean-going freighters. Four more ocean-going freighters are to be built when these two are completed, and contracts for two more are now being arranged, making eight boats to be built in all. These freighters will be the same size as the Thorjerd and Blaamyra, recently launched.

INDEX TO ADVERTISERS

The Chilled Iron Car Wheel in Steam Railroad Service*

By G. W. Lyndon**

The chilled iron car wheel has been, since its introduction in the year 1850, the standard accessory of transportation, carrying as it does the car and its contents to every nook and corner of this continent traversed and served by steam railroads. In the accompanying paper an interesting description is given of its development towards meeting the increased rolling stock weight and capacity that have been found indispensable to a continued industrial expansion.

THE subject of the Chilled Iron Car Wheel is one of vast magnitude, comprehending as it does the vehicle by which the commerce of this continent is moved; at the same time its importance to the transportation world is not as fully recognised as might be, either by the public generally or our industrial community particularly. Statistics which will indicate the extent of the car wheel industry are shown in the U.S. Interstate Commerce Report for the year ended 1914 as follows:—

Total number of freight cars in commercial service	2,325,647
Total number of freight cars in company service	124,709
Total	2,450,356
Add—Private car lines (approximately) ...	225,000
	2,675,356
Number of tons of freight carried, year ended 1914	1,109,271,040
Tons of freight carried one mile, 54% of car capacity, exclusive of private car lines ...	288,318,890,210
Tons of car structure (estimated 18 tons per car)	363,402,465,012
Total wheel burden carried one mile....	651,722,355,222 tons.

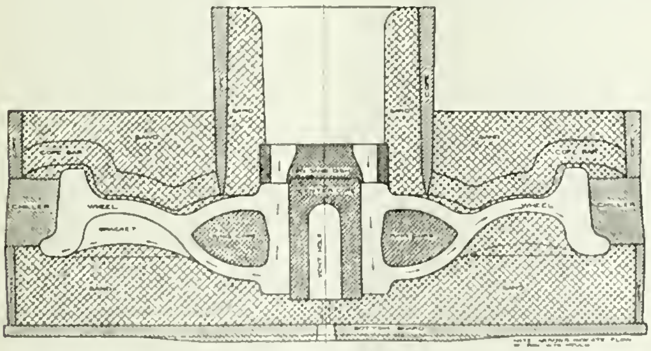

FIG. 1. CROSS SECTION OF CAR WHEEL MOLD SHOWING DIRECTION OF FLOW OF METAL.

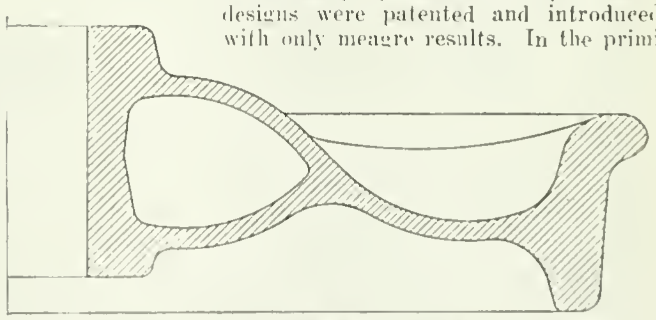

FIG. 2. WASHBURN PATTERN 525-LB. WHEEL FOR CARS OF 10 TONS CAPACITY.

An analysis of the rolling stock will show that 95 per cent. of all freight cars are equipped with the chilled iron wheel, therefore, we have, in commercial freight car service and company service, and private car lines in the United States alone, 20,332,687 chilled iron wheels. To this we must add the chilled iron wheels serving under passenger cars, engine tenders and street car lines, and we can safely and conservatively estimate the number of chilled iron wheels running to-day as about 25,000,000, taking into consideration those used in the Dominion of Canada, and the hundreds of thousands which have been shipped abroad and to Mexico and South America. 25,000,000 chilled iron wheels represent 8,000,000 tons of metal.

Initial cost at $25.00 per ton	$200,000,000.00
Scrap value at $15.00 per ton	120,000,000.00

25,000,000 wheels placed on a single track would make a solid line of wheels 13,000 miles in length, over one-half of the circumference of the earth. If they were placed on a single track with treads 2.3 feet apart they would encircle the globe. If they could be piled on top of each other, hub to hub, they would reach a height of 2,760 miles. To replace 25,000,000 chilled iron wheels upon the basis of 2,500,000 annual renewals requires ten years. 800,000 tons of metal are used annually to provide for 2,500,000 wheel renewals. From the receipt of the metal to the finished wheel ready for shipment, the metal must be handled about twelve times, so that to produce 2,500,000 wheels annually 800,000 tons of metal are required and 9,600,000 tons of metal must be handled.

I speak for twenty-five manufacturers operating fifty foundries scattered from the Atlantic to the Pacific Oceans, located throughout the United States and Canada, representing millions of invested capital, and having a combined capacity of 20,000 car wheels per day, and having in mind the statistics to which I have just called attention, we must remember that the history of the development of the resources of North America is a history of the development of the chilled iron car wheel, because the railways could not have reached their present unparalleled development without the chilled iron car wheel, and it would require years and years of preparation to replace them with any other substitute.

What Chilled Iron Is

Chilled iron means what the name implies and is the result of the chilling or sudden cooling of molten cast iron when poured against an iron ring, which is part of the mould. Its discovery is said to have been accidental. In an English foundry, in the 18th century, the slopping over of a ladle of cast iron caused part of its contents to come in contact with cold iron lying on the floor of foundry. In breaking up this scrap it was discovered that the iron was white and much harder than that secured from the ordinary foundry process of pouring the metal into a sand mould. The result of this discovery was the introduction of chilled iron for plow points, faces of forge hammers, punches for punching holes in wagon tires, and rolls for rolling materials.

Chilled Iron for Car Wheels

During the first half of the nineteenth century, a number of attempts were made to introduce chilled iron for car wheel purposes, and many different designs were patented and introduced, with only meagre results. In the primitive days the form of the wheel was the ordinary flat spoke pattern with the hub split longitudinally in three places. The separation of the hub was for the purpose of relieving shrinkage strains

*From a paper read, Feb. 13, at the Canadian Railway Club, Montreal.
**President, Association of Manufacturers of Chilled Car Wheels, Chicago, Ill.

in cooling and preventing the arms and spokes from breaking. The hub was banded together with a wrought iron band and keyed onto the axle. In the year 1838, Geo. G. Lobdell invented a double plate wheel, the front and back plates extending from the hub to the rim, which subsequently evolved into the present pattern.

In the year 1850, a man arose to the situation and developed an idea, the immensity of which was not dreamed of by him, but has since evolved into one of the most far reaching and important commercial industries in the country. From 1849 to 1860 there were eighty-eight patents granted for alleged improvements in the form of pattern. It was N. Washburn's belief that a solid casting weighing about 500 pounds could be produced that would serve as a car wheel which would require no machining, except as to axle fit and which could be placed into service under the then ten ton car and run on an iron rail for the life of the car.

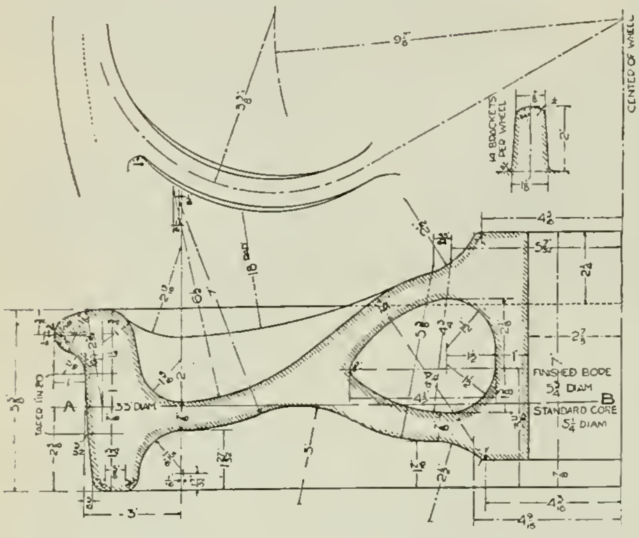

FIG. 3. M.C.B. STANDARD 625 LBS., 33-INCH C.I. WHEEL FOR CARS OF MAXIMUM GROSS WEIGHT, AND NOT EXCEEDING 95,000 LBS.

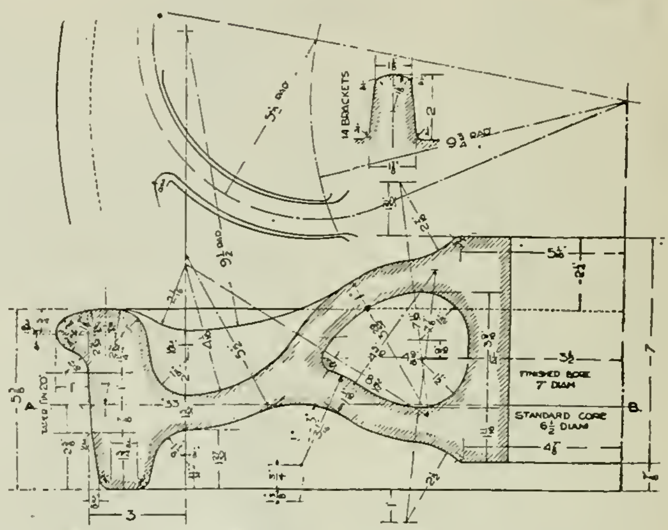

FIG. 4. STANDARD 725 LBS., 33-INCH C.I. WHEEL FOR CARS OF MAXIMUM GROSS WEIGHT, AND NOT EXCEEDING 161,000 LBS.

Method of Manufacture—Pouring

The method of manufacture in so far as the formation of the wheel is concerned, is practically the same to-day as when first introduced, and consists of pouring the iron into a mould, part of which is sand and part iron. The tread or running surface of the wheel is formed by an iron ring or chiller against which is poured the molten metal, and the sudden cooling of molten metal transforms the soft gray colored metal to a metal white in color and harder than tempered steel. This white, hard iron which extends all around the tread of the wheel to a depth of one-half to three-quarters of an inch, yields more mileage per unit of metal worn than any other metal. There is no other metal known that produces so hard a tread that can be operated with safety, because if other metals can produce a tread as hard as the chilled iron wheel this same hardness will be apparent in the plates and the hub, and, therefore, brittle and dangerous to use. Anyone by the use of the Scleroscope or Brinell methods can determine the relative hardness of the chilled iron wheel tread, as compared with other types.

The M.C.B. standard 725 lbs. wheel is poured in about twelve seconds. The balance of the mould consists of green sand and dry sand cores, all so scientifically arranged that the finished wheel possesses a gradual hardness of structure which is ideally adapted to service conditions, namely hard tread, soft plates and soft hub. Figure No. 1 shows a section of the mould in which the chilled iron wheel is cast, and the same principle of moulding has been in use ever since its introduction.

Annealing

We have found that a 725 lbs. M.C.B. wheel is poured in about twelve seconds. The molten metal is then subjected to different cooling conditions due to the complexity of the mould, which is made up partly of iron, partly of dry sand, and partly of green sand. That part of the mould which consists of iron is the best conductor of heat, therefore, the tread or running surface is cooled almost instantaneously, whereas the plates and the hub, having been formed by dry and green sand, cool slowly. In consequence, shrinkage strains are encountered which must be relieved before the wheels are placed in service. During the earlier periods of manufacture, after the wheel was set, it was covered with ashes or hot sand and allowed to remain several days until nearly cold. Another method was to lay the wheel on the floor and apply heat to the tread, so that the temperature of the tread would be brought back to that of the plates and hub.

These crude methods were later displaced with the introduction of cooling pits lined with fire brick, each pit holding from ten to fifteen wheels. Just as soon as the wheel is solidified, it is removed from the mould red hot and placed in a pit maintained at the proper temperature, and by this process the tread and the plates and the hub resume an equilibrium of temperature and the wheels remain in the pits for several days until the shrinkage strains are finally removed by the gradual and uniform cooling process.

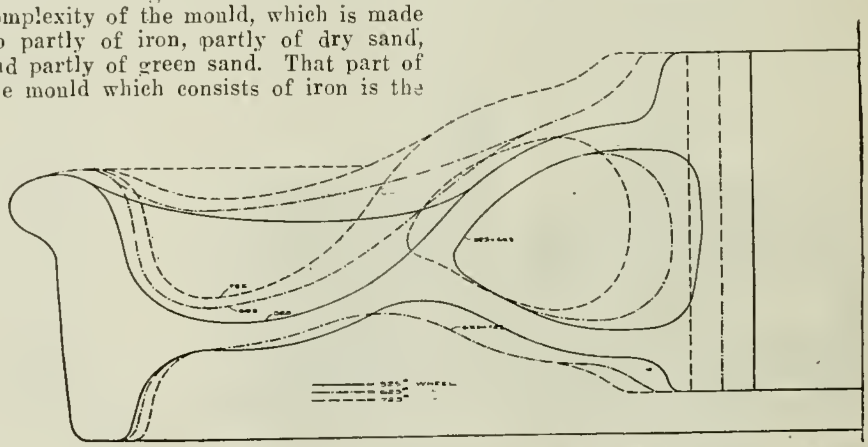

FIG. 5. COMPOSITE OF 525 LBS. WHEEL FOR CARS OF 10 TONS CAPACITY; 625 LBS. M.C.B. DESIGN FOR 30 TONS CAPACITY; M.C.B. DESIGN FOR 50 TONS CAPACITY CARS.

The pouring and annealing are important parts of the method by which the wheel is made, but they are only two of the multitudinous processes required.

The intricacies of manufacture are only recognized by those who have actually engaged in the business, and complex problems are continually confronting the manufacturer from the assembling of the material to the finished wheel.

We have found the method of manufacture as to pouring has not been materially changed, and we have also found that the pattern introduced in 1850 by Washburn is the same in outline practically as that in use to-day. It will, therefore, be my purpose to show what has been done, and it will be found that the only thing that stands out prominently is that a little metal has been added to the wheel as the capacity of the car has been increased, but the increase in metal has been "grudgingly made," and never proportionate to the increase of duty required. Nevertheless, the wheel manufacturers, in the face of restrictions in weight and flange dimensions, have been successful in maintaining the chilled iron wheel up to a high standard. The chilled iron wheel is like Topsy in Uncle Tom's Cabin. It just grew, and we all realize the fact that the wheel is the most important part of the car structure.

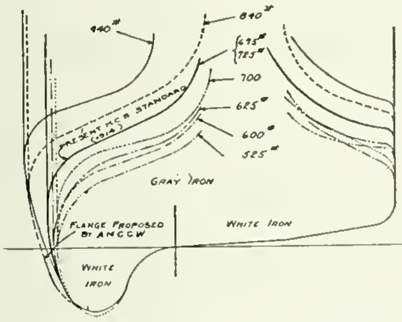
Increases in Car Capacity and Wheel Weights

A 33 ins., 525 lbs., chilled iron wheel of the Washburn type, as shown in Fig. 2, became standard soon after the year 1850 for 10 ton freight cars, and also for passenger cars. Cars of this capacity remained standard for about thirty years. As late as 1875 there were only occasional cars having a capacity as high as 12 tons. The heaviest capacity passenger coaches weighed 18 tons. Sleeping and drawing room cars of twelve sections weighed 30 tons. The operation of railroads then was very different than at present. Interchange of traffic as we now know it did not exist. An official of a great railroad charged another with running freight trains as fast as twelve miles an hour. "The wear and tear is something terrible," said he. "It is pounding the track to pieces. Every ton of freight handled at that speed is carried at a loss. The reduction of speed to eight miles an hour will lessen the cost more than $1,000 per day."

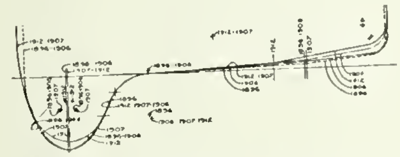
Such were the ideas of the foremost men in charge of transportation in the days of iron rails, hand brakes, link and pin couplers, fragile cars, etc. Under such conditions of light wheel loads, small flange pressures, slow speeds, low annual mileage, the wheels would last the entire life of the car. Wheel mileage obtained under such circumstances is sometimes erroneously used to indicate the superior service of wheels manufactured at that time. The ton mileage, which is the true basis for comparison, was extremely low as compared with wheel performance at the present time.

The introduction of the air brake, the automatic safety coupler, heavy steel rails, more rigid cars and interchange of traffic have permitted an era of rapid transit of heavy capacity freight cars with time schedules almost equal to that of express trains. Daily runs averaging thirty miles per hour, including stops, with an occasional burst of speed as high as fifty to sixty miles per hour, to maintain the high average rate is not uncommon.

The thirty ton car, introduced in 1885, was the heaviest capacity car on any railroad during the time of the World's Columbian Exposition at Chicago, in 1892. It was strongly argued at that time that the wheel load of 11,000 lbs., which was required under cars of 30 ton capacity was the maximum that could be carried on a 33 ins. diameter wheel, because the area contact between the wheel and rail being so small, any greater load would



DEVELOPMENT OF FLANGE AND TREAD OF THE CHILLED IRON WHEEL UNDER GROWING REQUIREMENTS.



CHANGES THAT HAVE BEEN MADE IN THE M.C.B. CONTOUR OF FLANGE AND TREAD, FIG. 6.

cause a permanent injury to both wheel and rail by reason of the fact that the elastic limit in the metal would be exceeded, resulting in dents in the rail and flat spots in the wheel tread.

Not only was 11,000 lbs. per wheel considered the maximum wheel load, but there was a good deal of doubt expressed by the foremost engineers as to whether this load was not in excess of good practice. The introduction of the 30-ton car was very rapid on all railroads. A chilled iron wheel weighing 600 lbs. was used under cars of this capacity and was recommended as standard in 1904 by the Master Car Builders' Association. It was later modified and the weight increased to 625 lbs. in the year 1909, upon the recommendation of our association. This standard is shown in Fig. 3, which represents the present M. C. B. standard.

Notwithstanding the doubt expressed regarding the maximum wheel load, cars of 40 ton capacity were soon tried out and found to be satisfactory and almost immediately thereafter the 50 ton car was developed for the coal carrying trade and found to be so satisfactory that cars of lighter capacity ceased to be built for this service. The 700 lbs. wheel was used under 50 ton cars and recommended as standard in 1904, by the M. C. B. Assn., but afterwards, upon the recommendation of our association, was modified to 725 lbs., and made standard in the year 1909. This design is shown in Fig. 4.

It will be noticed that in 1904, the first wheel made standard for the 50 ton cars weighed 700 lbs. In 1909 we succeeded in getting the weight increased 25 lbs. During the time intervening. a new wheel was introduced of the rolled steel type, and notwithstanding the alleged superiority of metal, the steel wheel substituted for the 700 lb. chilled iron wheel. weighed a minimum of 750 lbs. Fig. 5 is a composite drawing showing the contours of the early 525 lbs. wheel. and the present standard 625 lbs. and 725 lbs. wheels.

The present indications are that the 50 ton car is likely to be superseded in the very near future by the 70-ton car for carrying such commodities as coal, iron ore, etc. Cars of 70 ton capacity have already proven successful from every standpoint, and are being made in comparatively large numbers at the present time. The wheel proposed for this service by the Association of Manufacturers of Chilled Car Wheels is shown in Fig. 10.

The marvellous increase since the year 1875 in the capacity of cars and the tremendous tonnage hauled has called for an increase in the weight of the car structure, from 18,000 lbs. to 65,000 lbs. or 260 per cent. increase. There has also been an increase in the weight of rail from 50 lbs. to 125 lbs., or 150 per cent. increase. The axle has increased from 350 lbs. to 1,070 lbs.. or 200 per cent. increase; and the weight of the wheel from 525 lbs. to 850 lbs., or 60 per cent. increase. All of these increases are shown in the following table:

Capacity, lbs.	20,000	60,000	100,000	140,000
Per cent. of increase	....	200	400	600
Average wt. of cars, lbs.	18,000	30,000	12,000	50 000
Per cent. of increase	....	66	133	178
Weight of b'y. cars, lbs.	18,000	48,000	64,000	65,000
Per cent. of increase	....	166	255	261
Weight of axle, lbs.	350	550	870	1,060
Per cent. of increase	....	57	149	203
Weight of b'y. of car, lbs.	12,400	23,000	32,900	39,000
Per cent. of increase	....	86	165	215
Weight of wheel, lbs.	525	625	725	850
Per cent. of increase	....	19	38	62

It will be noted that the percentage of increase in the wheel is much less than for any other part of the car, and while the carrying capacity has increased from 10 to 70 tons, or 600 per cent., the weight of the heaviest M. C. B. standard wheel has increased only 38 per cent. This is a wonderful record for the performance of the wheel under adverse circumstances, when it is considered that not only has the capacity been increased but the speeds at which trains are operated have been increased 500 per cent. The ton miles per annum of the present 70 ton car is approximately twenty times that of the 10 ton car, which indicates the greater service given by the present wheel than

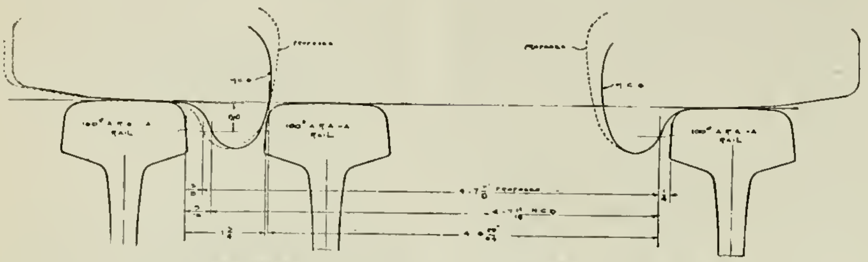


FIG. 7. RELATIVE POSITIONS OF M.C.B. AND PROPOSED FLANGES WITH REFERENCE TO GUARD RAIL WHEN ONE FLANGE IS AGAINST THE RUNNING RAIL.

was secured from any wheel during the pioneer days. It also plainly shows that the mere comparison of mileage is of no value whatever unless the load carried is taken into consideration.

The Flange

While the chilled iron wheel has always met increased requirements by reason of the rapid increases in the capacity of the cars, there is one part of the wheel that has received scant consideration, and that is the flange. The drawing, Fig. 6, will indicate all the changes that have been made since the wheel was first introduced, in the year 1850.

During all the remarkable railroad development, one dimension in track structure has remained constant. The space between the running rail and guard rail has remained fixed as one and three-quarter inches.

Chilled iron wheel manufacturers have ben trying for years to secure a stronger flange and have demonstrated the fact that three-sixteenths of an inch can be added to the thickness of the present M. C. B. flange, compensation for the increase being made in mounting each wheel three-thirty-seconds of an inch closer to the rail and still maintain the Master Car Builders' standard throat to back the flange dimension of 4 ft. 6 29-64 ins. This insures that the relation of the back of the flange to guard rail remains the same as at present and no change in track clearance is required. There can, therefore, be no objection from a track standpoint of making a liberal increase in the present flange thickness and we have received the approval of our plan from a special committee, who were appointed for the purpose of investigation through the American Railway Engineering Association.

Under the 10 ton car, whose weight was about equal to its capacity, the load carried per wheel was approximately 5,000 lbs., which would require about 4,000 lbs. flange pressure to change the direction of the truck in engaging curves.

Under the 70 ton car, the load per wheel has increased to 25,000 lbs., which requires almost 20,000 lbs. flange pressure to change the direction of the truck, therefore the flange thrust has increased 400 per cent. on account of the increased load, which is further augmented by the high speed of modern freight trains Under present conditions of operation, considering the increased load and speed the thrust on the flange, including impact, is at least ten times greater than under the old 10 ton car, and by consulting the chart showing the changes that have been made in the flange, it must be apparent that the increased duty has not been provided for.

Figure 7 shows the relative position of the M. C. B. flange and the proposed flange, recommended by our association with reference to guard rail, and it will be seen that the flange can be increased three-sixteenths of an inch when mounted as proposed, and there can be no greater impact blow against the guard rail than with the present M. C. B. flange. There are approximately one-half million wheels running to-day with flanges increased one-eighth inch. in thickness, and which have a throat to throat dimension of 4 ft. 7⅞ ins.

Relation of Wheel to Service Conditions

In the year of 1909, the Association of Manufacturers of Chilled Car Wheels made a study of the heat stresses developed in the wheel through brake application, and issued a pamphlet which was widely circulated, entitled the "Relation of Cast Iron Wheels to Service Conditions." It was our purpose to call the attention of the railroads to the fact that under present conditions of operation in some classes of service where high braking power is encountered, that the wheel was being subjected to uses for which it was not designed. This was particularly noticeable in cars of heavy tare weight. Under the thirty ton class of cars, one wheel weighing 625 pounds was introduced, in the year 1909, for use under any car whose gross load was 112,000 lbs., and the variation in the light weight of the cars in the thirty ton class is to-day from 23,000 lbs. to 53,000 lbs., approximately.

Inasmuch as the cars are braked at 60 per cent. of their light weight it was shown that one car of 46.000 lbs. light weight was subjected to twice the brake pressure of other cars weighing 23,000 lbs. in the same class of thirty ton cars and in the same train, and in consequence many wheels were subjected to heat stresses in excess of that for which they were originally designed. The result was that many wheels were removed on account of cracked plates, due to the excessive heating of the wheel on account of the strain in the plates, because the plates of the wheel were not designed or intended for one hundred per cent. increased duty. A cracked plate wheel should be rare if the plates of the wheel are designed for the maximum condition of service.

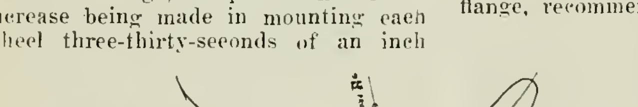

FIG. 8. WHEEL OF 675 LBS. PROPOSED BY THE A.M.C.C.W. FOR ALL CARS OF LESS THAN 40 TONS CAPACITY.

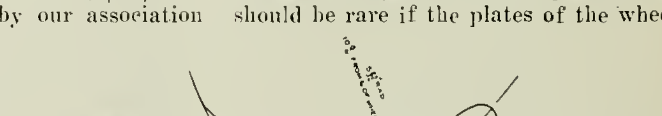

FIG. 9. WHEEL OF 750 LBS. PROPOSED BY THE A.M.C.C.W. FOR ALL CARS OF 40 TO 55 TONS CAPACITY.

The following table will explain the recommendation of the manufacturers with reference to plate thickness, and while these recommendations were made in the year of 1909, and based on 70 per cent. of the light weight of the car, the conditions confronting the manufacturers have not yet been changed.

plate developed while pressing on the axle. The ratio between these stresses developed in the seventy-ton car, as compared to the ten-ton car, is much greater

THICKNESS OF PLATES REQUIRED IN RAILROAD CAST IRON WHEELS TO TO WHICH BRAKES ARE APPLIED

Stress Tests

The University of Illinois, under the direction of our consulting engineer, F. K. Vial, have been conducting a series of tests for the purpose of ascertaining the magnitude of stresses to which the wheel is subjected in pressing it on to the axle and under various service conditions. These are enumerated as follows:

First—When a wheel is pressed on an axle, a compressive stress is developed radially and a tensile stress circumferentially. These stresses are of large proportion and extend all the way from the hub to the tread.

Second—The plate must carry the load, which produces a combination of stresses resulting in a wheel slightly elliptical.

Third—On descending grades the heat generated by the brake shoe, which is a factor of load, grade and speed, causes a tensile stress in a radial direction in opposition to the compressive stress which was developed while pressing the wheel on the axle.

Fourth—The heavy flange thrust causes a bending action in the plate which intensifies the tensile stress developed by the heat in the front plate and the compressive stress in the back

than that indicated by the mere increase in carrying capacity. The heaviest stress developed is probably that caused by the sudden rise in the temperature of the tread of the wheel from brake shoe application on descending grades. If we assume that trains are now operated at double the velocity they were forty years ago and the load on the wheels five times as great, there will be ten times the heat generated per unit of time on the tread of the present wheel, as compared to the wheel under the ten-ton car. Also the flange thrust being from five to ten times greater indicates that we have ten times the force to contend with that we formerly had.

Chilled Car Wheel Manufacturers' Recommendations

The information obtained would indicate that in order to design a wheel that will fit a given condition of service, it requires a thorough understanding of the intensity of the stress in each part of the wheel and the relation of the stresses to service conditions. Our association believes that due to the general conditions confronting us to-day, and considering the safety factor of operation, that three designs of wheels of 675 lbs., 750 lbs., and 850 lbs. respectively, with flange reinforcement of 3-16 in. for 30, 50, and 70-ton cars, would in a great measure solve our present troubles and our recommendations would be:

675 lb. wheel for cars having
  a maximum gross load of. 112,000 lbs.
750 lb. wheel for cars having
  a maximum gross load of. 161,000 lbs.
850 lb. wheel for cars having
  a maximum gross load of. 210,000 lbs.

drawings of which are shown in Figs. 8, 9 and 10 respectively.

Cost

I know of no railway material sold that is so necessary for operation, that comprehends so low an initial investment to the railway, as the chilled iron wheel. The eight million tons of chilled iron wheels running to-day possess a higher relative market value when worn out, based upon their first cost, than is usual with other commodities purchased by the railroads. Worn out chilled iron wheels are as staple as sugar, and are worth about sixty per cent. of the original selling price; therefore, if you purchase wheels at $25 per ton, the manufacturers will immediately accept in part payment for the new wheels, old worn out wheels at approximately $15 per ton.

Hundreds of thousands of chilled iron wheels have been sold at a differential of $10 per ton, which represents the difference between the original selling price and the scrap value of the old worn out wheels, and this $10 per ton differential represents the cost of reconverting the old wheel into a new one, plus the necessary labor, plus the price of the

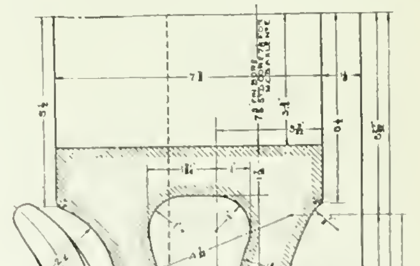

FIG. 10. WHEEL OF 850 LBS. PROPOSED BY THE A.M.C.C.W. FOR ALL CARS OF 60 TO 70 TONS CAPACITY.

new material and the profit of the manufacturer. Special wheels are purchased by many railroads at a higher differential than $10 per ton, and some foundries located in remote parts of the country far from the raw materials, such as coke and pig iron, must receive a higher price. The profit on a chilled iron wheel is so low that a fifteen cent freight rate will often absorb the profit on the wheel.

Contracts with railways provide for an equal exchange of tonnage of old wheels, and it is not necessary to exchange the identical worn out wheels to the manufacturer. Any chilled iron wheel, no matter where or by whom made, is accepted in part payment for the new wheels, and wheels made in Canada may find their way into the exchange market of Texas, and wheels made in California are exchanged in Massachusetts or vice versa, and as there are fifty foundries conveniently located throughout the United States and Canada which are accepting all makes of wheels in exchange, a ready and economical solution of teh old wheel problem is provided. The commonest kind of castings, such as sash weights, which require no skill to manufacture, and which have no duty to perform except as counterweights, cannot be purchased as cheaply as chilled iron wheels.

About thirty per cent. of all wheels sold are removed by foreign lines and the price paid for these removals is fixed by the printed interchange rules of the Master Car Builders' Association, as follows:

	Chilled iron.	Steel.
New value, each	$9.00	$19.50
Scrap value, each	4.75	4.50
Net cost	$4.25	$15.00
Cost of removing from and replacing in trucks, per pair $2.25, each ..	1.12	1.12
Cost under car, each..	$5.37	$16.12
Cost of two turnings..		3.25
Total cost of wheel service, each	$5.37	$19.37

It will be observed that the total cost for wheel service for other types of wheels is about four times that of the chilled iron wheels, and upon this basis of comparison any substitute must yield four times the mileage or time service in order to equalize the cost. As the Master Car Builders fix the price of removals on 30 per cent. of your equipment, it must follow that the same relative basis of cost must apply on the 70 per cent. of removals on your own lines.

Chilled iron wheels sold at a differential of $10 per ton makes the net cost of the three Master Car Builders' standards as follows:

625 pounds M.C.B. wheel for 30-ton cars	$3.12
675 pounds M.C.B. wheel for 40-ton cars	3.37
725 pounds M.C.B. wheel for 50-ton cars	3.62

All chilled iron wheels, unlike other types, are guaranteed for a minimum service, and the usual guarantee in the States is:

625 pounds M.C.B. wheel for 30-ton cars	6 years
675 pounds M.C.B. wheel for 40-ton cars	5 „
725 pounds M.C.B. wheel for 50-ton cars	4 „

Should any of these wheels fail in service through the fault of the manufacturer a new wheel is supplied without any cost to the user.

Maximum net cost of 625 lb.
M.C.B. wheel gtd. 6 yrs...52c per year
Maximum net cost of 675 lb.
M.C.B. wheel gtd. 5 yrs...67c „ „
Maximum net cost of 725 lb.
M.C.B. wheel gtd. 4 yrs...90c „ „

Any wheel that is sold for $20 will cost the railroad, in interest charges alone (figured at 5 per cent. per annum), more than the renewal charges of the chilled iron wheel, because while the guaranteed net cost to the railroads is based upon six, five and four years' service respectively, the actual service is often twice as much. During the two years last past, the price of all commodities have reached their highest figures. Nevertheless, the price of the chilled iron car wheel has practically remained constant. Based upon the annual renewals of 2,500,000 wheels any other substitute at a price of $20 per wheel will cost the railroads $50,000,000 initial investment the first year.

NO APPEALS FROM BUSINESS TAX

NOT a single appeal from the business tax, imposed last session, has so far been received by the Finance Department, Ottawa. This is an entirely unexpected state of affairs, arrangements having been made for the appointment of Boards in the various districts before which the appeals expected to be made, could be heard. So far however no need has been found for them. That this is so, is attributed by the Finance Department, largely to the patriotic spirit shown by Canadian business men in remitting the assessments.

The business tax collections during the present fiscal year, it is estimated, have produced over the ten million dollars expected. The tax collected was on the basis of 1914-15 profits which were, as a rule, small owing to the disorganization of business produced by the first outbreak of war. Next year's results will be much greater. The tax will not be operative after the present year but collections will continue to be made for a year after that.

B.C. LUMBER OUTPUT INCREASE

WHILE the preliminary figures have not yet been compiled, it is stated that the value of the lumber cut for the Province of British Columbia in 1916 will show a satisfactory increase over that of the previous year, when the value was put at $29,150,000. The demand for lumber during the past year showed an improvement, and prices generally were higher than the year before. The best previous year was 1913, when the value of the cut was $33,500,000. It is predicted that this year's value will be well up to this latter figure. A feature of last year's lumber business has been the increase in shipments to Ontario, where the late Government carried on an aggressive campaign to popularize the British Columbia product. The demand there has resulted in doubling shipments from this Province, especially for floorings, paneling, mouldings, etc. The fact that these shipments have been made by rail indicate the popularity which the British Columbia products have secured in the East.

RAILWAY FACILITIES INADEQUATE

THE Canadian Bank of Commerce, in its commercial letter for February, contends that the railway connections between Canada and the United States coal fields and industrial centres are inadequate. Upon this topic it says: "During January, Canadian railways found great difficulty in handling satisfactorily the unusually heavy volume of traffic which has originated, partly from the continued industrial activity and partly from an unusually heavy movement of field products. The outstanding factor in maintaining this state of affairs is, of course, the urgency of the demand for our agricultural products and for munitions of war. Large quantities of partially manufactured materials are being imported to enable Canadian factories to meet the latter demand as well as that for goods for the home market.

Activity so general, especially in the industrial centres, has created an abnormal demand for additional power and fuel. In that part of Ontario served by the electric current generated at Niagara Falls, there is a continuously increasing demand for power, and special arrangements have had to be made through Government agencies to provide for the increase. Many industrial establishments are being inconvenienced through lack of coke and steam coal. These facts serve to show the character of the prevailing industrial activity, and, taken in conjunction with the difficulty of obtaining deliveries in reasonable time, indicate the inadequacy of existing railway connections with the United States coal fields and industrial centres. The congestion at Buffalo and Detroit, where so much traffic enters Canada, is a contributory cause of the difficulty in Ontario."

Tin-Plate Shortage.—Officials of the Department of Trade and Commerce at Ottawa state that there is a shortage of tin-plate in Canada. This is due to lower production in England, and to the shipping situation. The department thinks that steps should be taken to collect all the tin available, such as tin boxes and cans, in order that it may be used over again. It is believed that if some systematic plan of collection is adopted the shortage of the tin-plate will be largely made up.

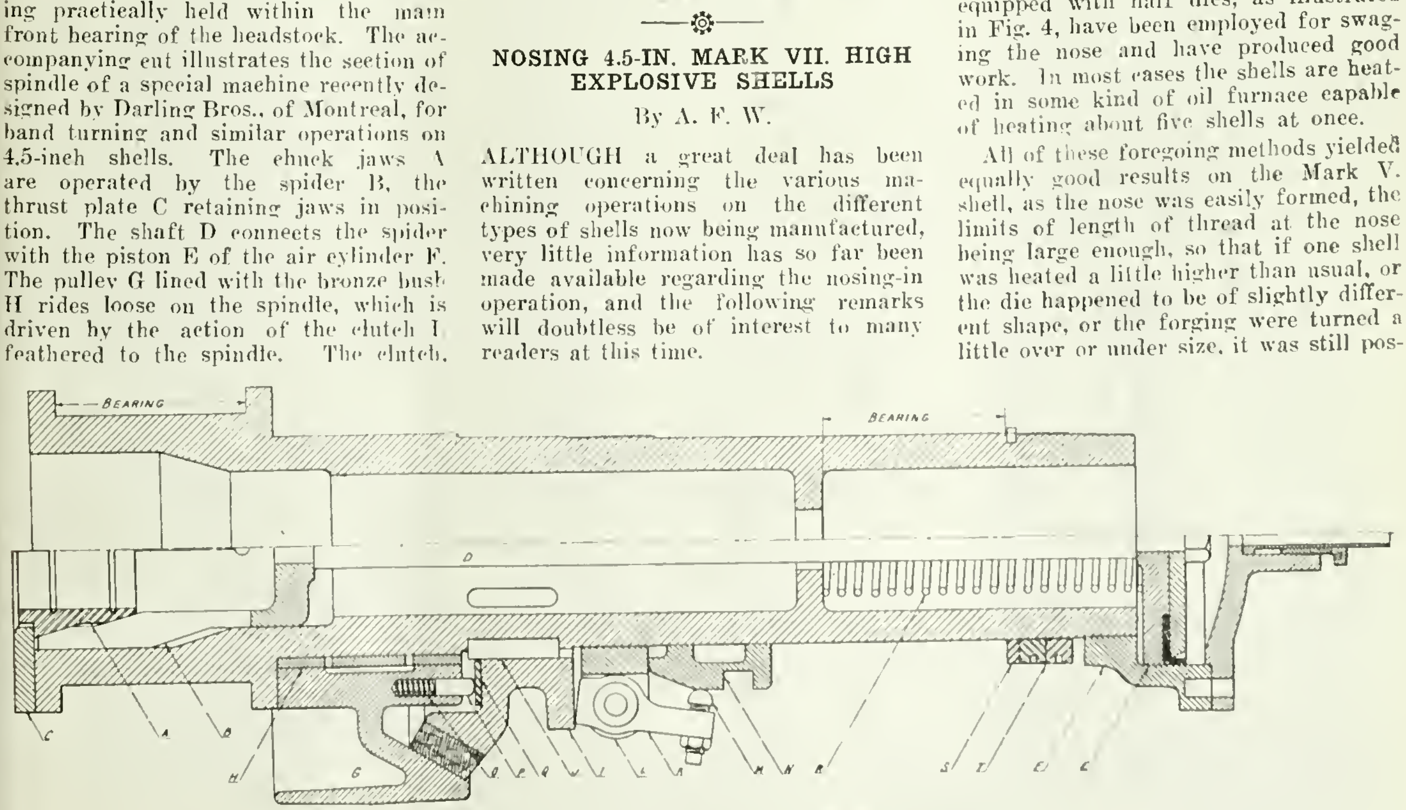
SPECIAL DESIGN HEADSTOCK SPINDLE

By J. H. R.

RIGIDITY in machine tools and auxiliary equipment is undoubtedly one of the chief essentials in the successful manufacture of munitions. Machining a shell requires special facilities for rapid and economical production. As in most other classes of work, the setting generally occupies much more time than the actual tooling operations, and it is this feature of shell making that has probably received greater attention than some of the other details. Standard lathe designs were early found to be unsuited for rapid handling of shells, the chucking problem being one of the chief factors that led to the radical departures from precedent with which all of us are now more or less familiar. Many machines, while differing greatly from standard in several respects, still require special chucks or attachments for holding the shells. In a large number of cases lathes had to be fitted with special steady-heads to support the outer end of the shell or fixture, so as to prevent the overhang from affecting the alignment, and also to avoid vibration under the heavy cuts required.

Manufacturers, however, are rapidly realizing the advantages of maximum rigidity, and machines are now being designed so that the spindle is constructed sufficiently large to contain the chuck and operating mechanism, the shell being practically held within the main front bearing of the headstock. The accompanying cut illustrates the section of spindle of a special machine recently designed by Darling Bros., of Montreal, for band turning and similar operations on 4.5-inch shells. The chuck jaws A are operated by the spider B, the thrust plate C retaining jaws in position. The shaft D connects the spider with the piston E of the air cylinder F. The pulley G lined with the bronze bush H rides loose on the spindle, which is driven by the action of the clutch I feathered to the spindle. The clutch, which is fitted with wooden blocks, is operated by the dogs K held in the adjustable collar L, the pressure bolts M being forced outwards by means of the wedge collar N operated by a lever on the front of the machine. Connected to this lever is the air operating mechanism, so that the one movement operates the air chuck, and also starts or stops the machine. The clutch is released by the action of the pin P forced out by the spring O, a steel washer preventing the pins from cutting into the cast iron clutch. The spring R forces back the piston when the air is released. Adjustable thrust collars are provided at the back end of the rear bearing.



SPINDLE ASSEMBLY FOR BAND TURNING MACHINE.

NOSING 4.5-IN. MARK VII. HIGH EXPLOSIVE SHELLS

By A. F. W.

ALTHOUGH a great deal has been written concerning the various machining operations on the different types of shells now being manufactured, very little information has so far been made available regarding the nosing-in operation, and the following remarks will doubtless be of interest to many readers at this time.

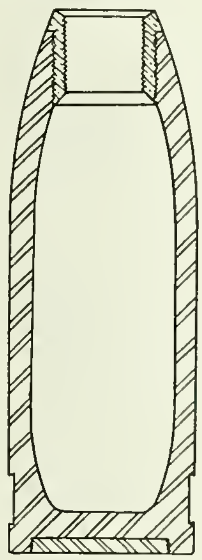


FIG. 1.

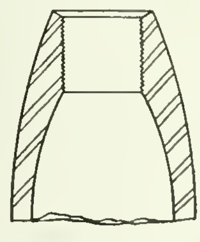

FIG. 2.

The 4.5 H.E. shells were the first shells of this type to be made with a formed nose, the design known as Mark V., see Fig. 1, having a brass socket fitted at first, which, however, was expensive, the design being afterwards changed so as to have the nose completely formed to size, integral with the shell body, as shown in Fig. 2, this being latterly the standard design of Mark V. shell.

The most common method of forming the nose is by pressing the shell forging into a suitably shaped die, mounted in a hydraulic press of the type shown in Fig. 3. Bulldozers, equipped with similar dies, have been used by firms who already had such machines installed for other purposes, and power hammers, equipped with half dies, as illustrated in Fig. 4, have been employed for swaging the nose and have produced good work. In most cases the shells are heated in some kind of oil furnace capable of heating about five shells at once.

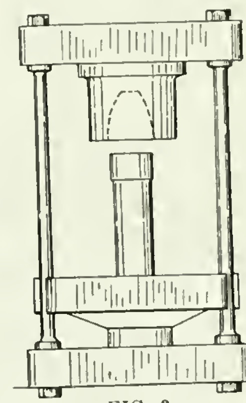

FIG. 3

All of these foregoing methods yielded equally good results on the Mark V. shell, as the nose was easily formed, the limits of length of thread at the nose being large enough, so that if one shell was heated a little higher than usual, or the die happened to be of slightly different shape, or the forging were turned a little over or under size, it was still possible to produce a correctly machined shell within the specification requirements.

Mark VII. Design

The Mark V. shell however, did not

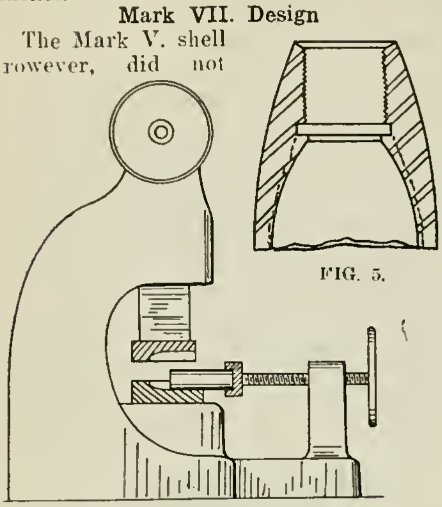

FIG. 4.

FIG. 5.

give entire satisfaction in use, hence our "misfortune" to be called on to make Mark VII. design (see Fig. 5.) At first sight the change seemed slight and innocent enough, the apparent difference from Mark V. being very small; yet it proved to be much more difficult than appeared, and many shell makers now changing over to this design are having their troubles. With the Mark V. design, the closing in the end thickened up the material just sufficiently to form the nose satisfactorily, but on comparing the two designs, as in Fig. 5, it will be seen that more metal has to be put into the nose for Mark VII. design. To do this satisfactorily, the shell must be upset, and the use of a hydraulic press, in the writer's experience, is the most satisfactory method of insuring uniform work; the bulldozer, unless exceptionally heavy, would not be suitable owing to the extra pressure necessary, while the swaging effect of the hammer does not upset the metal sufficiently.

Rough Turned Sizes

In Fig. 6 is shown a forging rough turned to dimensions for the Mark V. shell, and the same design made 1/4 in longer gives a good Mark VII. nose, with rather an excess of metal to remove. The form shown in Fig. 7 will also make a good Mark VII. nose, but great care must be taken in heating, as there is very little extra metal, and consequently less to machine off inside after forging.

A forging roughed to the dimensions given in Fig. 8 can be safely nosed-in with a hammer, but the standard forgings are not large enough to machine up to this size, and special forgings have to be obtained: the hammer, however, is being used by those firms who had them previously installed for the Mark V shell, but many forgings are spoiled, and have to be reclaimed by socketing when the fuse seat does not clean up.

Heating the Nose

When nosing with a press, the depth of nose inside the shell depends entirely on the temperature and the distance from the end to which the shell is heated, always provided that there is sufficient metal in the forging to make the nose. For instance, take forging, Fig. 6, and heat it to a good white heat about

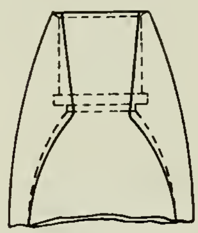

FIG. 9.

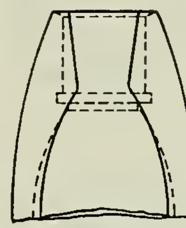

FIG. 10.

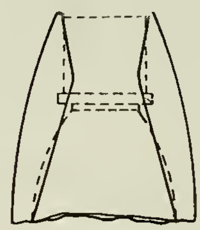

FIG. 11.

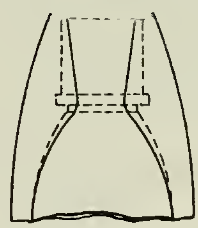

FIG. 12.

$4\frac{1}{2}$ in. down and a section will be obtained, as shown in Fig. 9, which is of no use. A forging of this shape, heated about 3 in. down, will yield the section shown in Fig. 10, which has lots of metal in the right place.

Again, take forging roughed, as in Fig. 7, and heat it to a good white soaking heat about $2\frac{3}{4}$ in. down, and an even better section will be obtained, Fig. 11, with less metal to remove from the bore. Care must be taken when heating this design, because if the heat be allowed to

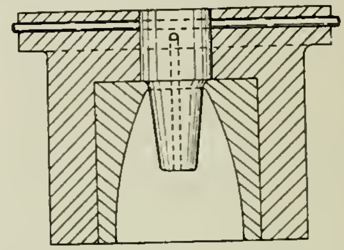

FIG. 13.

travel beyond 3 in. from the end, the section shown in Fig. 12 will result.

Use of Pin in Die

To get any of these sections, a pin must be used in the die to limit the closing of the hole and cause the die to exert an upsetting effect on the heated portion of the walls; the use of this pin was not necessary with Mark V. shell. A die-holder and pin, as designed and used by the writer, are shown in Fig. 13. The die-holder is of cast iron, and the die itself of special chilled cast iron, the pin being of soft steel case-hardened. The chilled die will usually nose from 10,000 to 15,000 Mark VII. shells, although a die of this type has nosed as many as 27,000 Mark V. shells, and when removed was in good condition, which is pretty conclusive evidence of its superiority.

Pin Dimensions

It is necessary to change the pin about every 5,000 shells, and for this reason it should be made as simple as possible, and easy to remove without disturbing the die. The dimensions of the pin are given in Fig. 14, the hole A being made to coincide with a hole in the holder, which is coupled up to the air line which supplies pressure to force the shell out of the die after pressing. The inside of the die and also the pin should be painted over every impression with a mixture of graphite and water mixed to a paste, which prolongs the life of the die and produces better work.

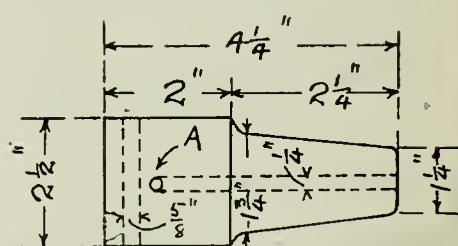

FIG. 14.

It is well to have a number of pins made up, as, after pressing from 3,000 to 5,000 shells, the pin becomes a little rough and should be removed and another inserted; the old pin can be quite well ground up smooth and used repeatedly, or else softened, filed up, re-hardened and polished.

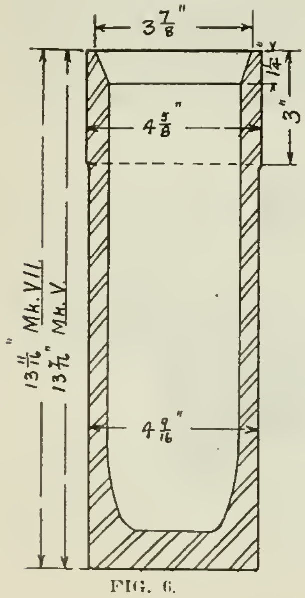

FIG. 6.

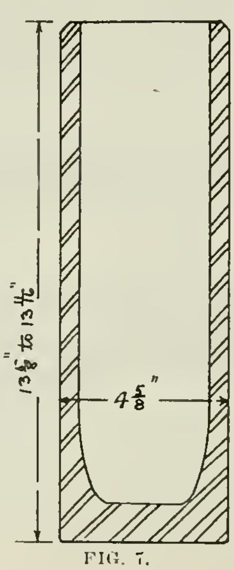

FIG. 7.

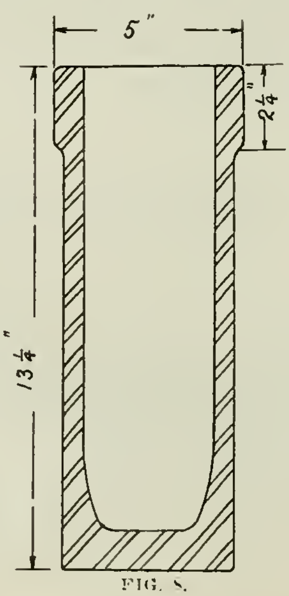

FIG. 8.

SAFE OXY-ACETYLENE WELDING EQUIPMENT

WITHIN the last few years oxygen and acetylene gas in combination have come into general use both for welding and for cutting metals. The high temperature of the flame (6,000 degs. Fah., or more), and the oxidizing effect that is obtained when the burner is supplied with an excess of oxygen, make it possible to cut heavy steel objects with great rapidity, and under circumstances where it would be exteremely difficult to do the same work by any other means. The oxy-acetylene torch is also capable of producing excellent welds, when it is operated by an expert workman, and repairs can be quickly and cheaply made by it, where otherwise the necessity for procuring new parts, or perhaps manufacturing them, would cause expensive delays.

Nowadays an oxy-acetylene welding outfit is to be found in nearly every large modern machine shop and repair shop. The equipment comprises an acetylene gas generator (or one or more tanks of compressed acetylene gas), together with cylinders of compressed oxygen, and suitable torches for welding and cutting. In addition, there must be effective regulating devices to furnish a proper mixture of oxygen and gas to the torch, at a suitable pressure, and special hose must also be provided to transmit the gases from the generator or tank to the tip of the torch where they are mixed.

Generator Feature

In shops where a large amount of welding is constantly being done, the acetylene gas is often manufactured on the premises, by bringing calcium carbide in contact with water in a suitable generator. Nearly all generators now in use are automatic in action, the gas-producing operation being controlled by a "bell" in which the gas is stored, and which, by alternately rising and falling as the acetylene is generated or drawn off, starts and cuts off the carbide feed.

Formerly, this generating process was attended by considerable danger, and a number of serious accidents occurred because attempts were made, often through inexperience, to generate the gas under pressure, and to store it in unsafe receptacles—such, for instance, as ordinary kitchen hot-water tanks. Pressure generators are little used at present, however, in connection with welding outfits, and if the dangers associated with them were generally understood it is doubtful if the authorities who have charge of such matters would permit them to be employed or operated under any circumstances. Acetylene gas should never, under any conditions, be generated under a pressure exceeding 15 pounds per square inch. Many generators are now manufactured which provide acetylene gas at a suitable pressure and which are equipped with appropriate safeguards. These have been approved by the National Board of Fire Underwriters, and a selection should be made from them when purchasing a self-generating welding outfit.

In many cases a portable welding or cutting outfit is necessary, because the work cannot be carried to a repair shop. Portable generators may be had, but it is often inconvenient to transport them to the scene of the operations, and therefore steel cylinders containing compressed acetylene are used.

Unabsorbed acetylene is highly explosive at a pressure of two atmospheres or more. We do not refer, here, to the possibility of exploding a mixture of acetylene and air by means of a flame or spark, but to the chemical instability of the gas itself. Acetylene is what chemists call an "endothermic" compound, and all compounds of this nature are more or less unstable, and liable to sudden explosive decomposition under certain circumstances—and accidents of this kind sometimes occur when it is not possible to guess what it was that precipitated the decomposition. Acetylene gas at ordinary atmospheric pressure and temperature does not spontaneously and explosively fly apart into its constituents, but when it is subjected to a considerable pressure, while in a wholly gaseous condition, it is likely to explode, as here indicated, without the slightest warning.

Acetylene Storage

Two French engineers, Claude and Hesse, made the exceedingly important discovery, however, that acetone has the remarkable property of absorbing about 25 times its volume of acetylene for each atmosphere of pressure at 60 degs. Fah., and that acetylene, when dissolved in this way, ceases to be spontaneously explosive, so that it may be stored in connection with acetone at pressures up to 250 younds with comparative safety. To store acetylene safely, by this method, the metal container must first be completely filled with an approved porous substance of some kind, such as asbestos, leaving no voids where gas might accumulate even in small quantities. The porous filling must be constituted and arranged in such a way that it will not disintegrate nor change its position when wet, or when the cylinder is subjected to ordinary handling. Acetone is then introduced in quantity not exceeding 40 per cent. of the interior cubic capacity of the tank, after which the acetylene may be forced in until the desired pressure is reached. This pressure, however, must not exceed 250 lbs. per square inch, at a termperature of 70 degs. Fah. Persons who are not fully acquainted with the properties of acetylene should never undertake the compression of acetylene gas.

Handling Acetylene Gas Tanks

Certain precautions should be observed in the handling of charged acetylene gas tanks. In shops where a number of tanks are kept on hand constantly, it is advisable to provide special storage places for them. The cylinders should not be allowed to remain near stoves, furnaces, steam radiators, nor other sources of heat, nor should they be exposed unnecessarily to the direct rays of the sun, because the application of heat is likely to increase the pressure in the cylinders, or (in extreme cases), to soften the fusible safety-plugs with which they are provided, so as to permit the gas to escape. These fusible plugs, which melt at a temperature of about 240 degs. Fah., are provided for the purpose of preventing explosions in case of fire, and tanks that are not fitted up with such plugs should not be used. Care should be taken to protect the discharge valves and safety devices against damage caused by heavy objects striking them, or by the tanks falling over.

Leaking cylinders must be condemned, and they should be set out in the open air as soon as discovered, and disposed of in such a manner as to effectively prevent any possibility of ignition of the gas, or of the mixture of gas and air that surrounds the leaking cylinders. No repairs should be attempted, but the charging station where the cylinders were filled should be notified concerning the condition of the cylinders. Open-flame lights should not be taken into confined spaces where there is any possibility of leakage of acetylene, because this gas is explosive when combined with air in widely varying proportions. Never use a lighted match, nor flame from any other source, for the purpose of detecting leaks in tanks. Leaks may be located by closing the discharge valves, applying soapy water to the outside of the suspected cylinders, and watching for the bubbling that the escaping gas produces.

Care of Oxygen Cylinders

Similar precautions are applicable to cylinders containing the compressed oxygen which is used in combination with acetylene gas to produce the welding and cutting flame. Oygen is stored in metal cylinders, usually at a pressure of about 1,800 pounds per square inch, and it is easy to see that an explosion of one or more of these heavily-charged cylinders might result disastrously. Care should be taken to avoid mixing acetylene and oxygen at any time. A combination of the two gases under any conditions—such as might be effected, for example, by an interchange of hose or piping—may be highly explosive.

Oxygen clinders should not be dropped or handled roughly in any other way, and they should be placed so that they cannot be overturned either by collision with some other object, or by the reaction due to the violent escape of their contents through the safety outlets with which they are provided. The valves, regulating devices, and other attachments should not be lubricated with oil or grease, because violent explosions may be caused by oil or grease coming in contact with compressed oxygen. In fact, a large proportion of the explosions and fires that have been caused by compressed oxygen, in recent years, have been demonstrably due to the use of grease or oil for lubricating purposes. Pure graphite should be used (unmixed with oil or grease), if any lubrication is needed. The discharge valves of oxygen tanks should be opened slowly, and special care should be taken to avoid twisting or straining them by the use of hammers or improper wrenches.

In many cities there are regulations governing the storage of explosives and other dangerous substances, and in such cases charged cylinders containing compressed gas of any kind are often counted as "explosives," certain stipulations bein made as to the number of cylinders that may be kept on hand. Attention is called to this fact in order to emphasize the importance of using care in storing and handling these cylinders. Like acetylene-gas cylinders, oxygen cylinders should never be allowed to remain near heating appliances, nor in any place where they might be exposed to sparks or flames.

Pressure Regulating Devices

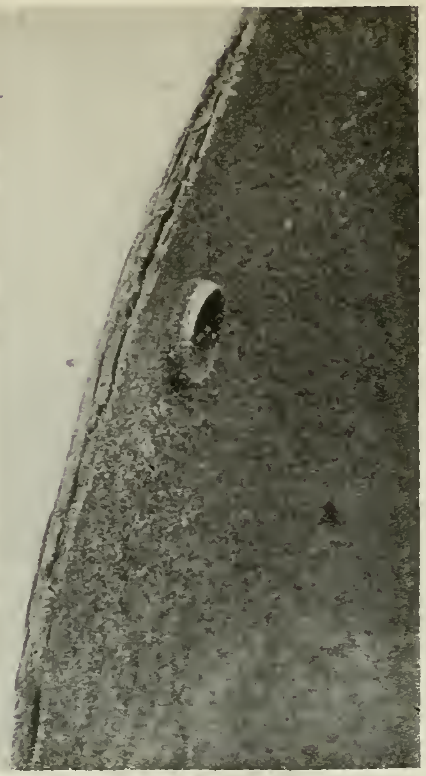
Every welding and cutting equipment should include approved pressure-regulating devices for controlling the flow of acetylene and oxygen to the torches and to indicate the pressure in the tanks and also the working pressure. The torches and regulators used should be the best obtainable, and they should be constructed so that back-firing to the acetylene tank will be impossible. All hose connections and fittings of every kind should be of high quality, and should be kept in first-class condition in every respect.

To insure safety in the use of oxygen and acetylene gas for welding and cutting, no operators should be employed except men who have given satisfactory evidence that they are both competent and careful. Many accidents have resulted from the careless and unintelligent handling and operation of an equipment of this kind. Moreover, it should be remembered that the danger is by no means confined to accidents with the welding equipment itself, but that imperfect workmanship may result disastrously at some later time. When safety to life and property depend upon the strength of a certain welded joint, for example, it is highly important to have this joint made by a man of exceptional experience and intelligence.

Pure acetylene gas is now known to be comparatively non-poisonous, when inhaled in highly diluted form in small quantities, in consequence of slight leaks. The poisonous effects that have been observed in connection with it, and which were formerly attributable to the acetylene itself, are now known to be mainly due to the presence of impurities such as phosphoretted hydrogen. To avoid dangers of this kind as far as possible, the acetylene should be purchased of dealers who are prepared to furnish gas as free as possible from phosphorus and other objectionable contaminating substances.—Travellers Standard.

AIR CYLINDER EXPLOSION

AN alarming explosion of a compressed air cylinder worked in connection with a large gas engine has come to our notice, says *Vulcan*, and as so many of these high-pressure cylinders are now in use for starting purposes, the facts of the case are of interest.



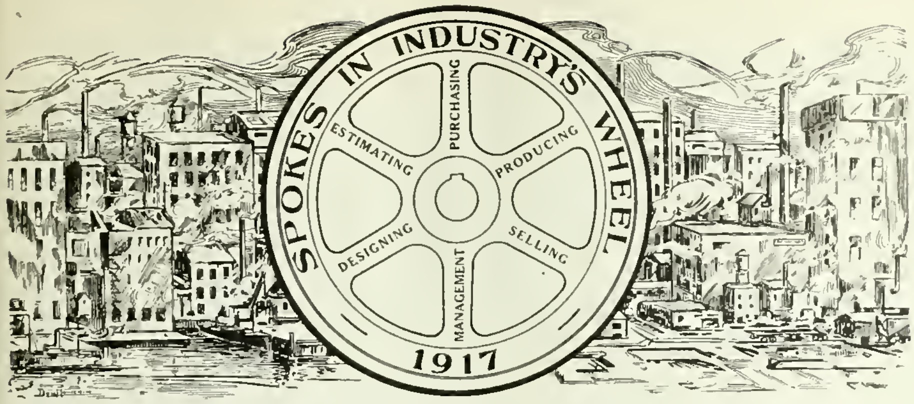
LAMINATIONS IN EDGE OF FRACTURED COVER.

It is sometimes asserted that air receivers are not liable to corrode or develop other defects on the inside, and, apparently, in accordance with this view many receivers are made without provision for internal examination. Experience with these vessels, however, shows that there is sufficient moisture in the air to cause serious corrosion, and that this is often aggravated by grease deposited from the compressor. For this reason facilities should always be afforded in air cylinders for proper periodical cleaning and examination on the inside. The ends of such cylinders also should be of ample strength and well dished, unless otherwise strengthened by stays.

The cylinder in question was worked at a pressure of about 200 lbs. per square inch, and was made of iron plates about 3/8 in. in thickness originally. The ends were nearly flat and the material, judging from the quality of the end which failed, was of very inferior quality. This plate was badly laminated for nearly its whole circumference and also corroded, and owing to the panting action which inevitably occurred with a circular flat plate under the working conditions, grooving was set up at the root of the flange attaching the end to the cylindrical body and eventually weakened the end to such an extent that it was blown out. The explosion was a violent one, the top end of the cylinder being thrown through the roof and into a field about 100 yards away. The windows of the engine house were damaged and the engine attendant had a narrow escape.

Air cylinders of this type intended to work at high pressures should be very carefully designed. The material should be of the best mild steel of ample strength, and for a diameter of 2 ft. the size of the cylinder in question, the ends should have been about 1/2 in. thick and dished to a radius not greater than diameter of the receiver, which in the present instance would have been about 4 in. to 5 in., whereas the actual camber of the ends was only about 3/4 in. Where flat or nearly flat ends are used the plates should be adequately stayed with bolts or other means. Should an air receiver be too small to fit an ordinary pressed steel manhole and cover, hand or side openings should be provided.

END OF AIR CYLINDER SHOWING FRACTURE.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

HARRY ALTON WILSON

OF all the crafts represented in the activities of the war, that of engineering in its every aspect is dominant. The establishment of a munitions industry in Canada some two and a half years ago, and the extraordinary extent to which it has since been developed, serve of themselves to bring the truth of this statement quite forcibly home to us. Our metal-working plants, whether in their individual or corporate constituent, have, so to speak, found their feet, as a result of war-made opportunities thrust at them, which is equivalent to saying that they have become alive to their capacity for doing things, and, in consequence, have uncovered an expertness that was previously considered non-existent, and still less believed to be simply latent. Administrative business sense has been quickened and its outlook broadened, and what in this respect is applicable to the executive is equally so with regard to the employe-staff or operative, in his capacity of a Spoke in Industry's wheel.

Opportunities for the display of worth-while inventive genius such as the munitions industry has provided have been rare indeed; further, to the man with grit and balance, and who is at the same time well grounded in his profession, the prospects of achieving success as a result of embarking in manufacturing enterprise have at no time in our history been so alluring as during the past thirty months or so. Within the period indicated there has not only been witnessed a widespread and numerically large redistribution of employee appointments, in our previously established metal-working shops, but the interesting phenomenon, as well, of men hitherto under more or less direction, transferring themselves to positions of administration through their institution of new munitions manufacturing enterprises. Our "Spoke" this week, Harry Alton Wilson, superintendent, J. C. Wilson & Co., Belleville, Ont., is of the latter.

Alton, by which title he is addressed by those most intimate with him, was born at Glenora, Ont., April 17, 1890, of Canadian parents, and received his education at Picton Public School, Picton, Ont.; Highfield School, Hamilton, Ont., and Faculty of Applied Science, University of Toronto, of which he is a graduate in Mechanical Engineering. Previous to his university course and during and following same, he served as apprentice machinist in the shops of J. C. Wilson & Co., Glenora, Ont., in 1912 emerging as a full fledged mechanic.

HARRY ALTON WILSON.

From February, 1912, until June, 1915, he set himself to acquire as wide a grasp of practical engineering experience as might be available in the time, hence we find him on the editorial staff of this journal for the first three months of the period. From May, 1912, until November, 1913, he was assistant superintendent with J. C. Wilson & Co., Glenora, following which he took a position with the Cadillac Motor Car Co., Detroit, as tool, jig and fixture designer. In July, 1914, he became editor in Montreal for the J. B. MacLean Publishing Co. mechanical papers, holding that position until June 1915, when he resigned to assume his present appointment with J. C. Wilson & Co.

Almost immediately thereafter, his firm started in to the machining of Mark V., 4.5 in. high explosive shell. In order, however, to secure not only more efficient production, but to eliminate transportation and labor inconveniences incidental to the shop's location at Glenora, it was deemed advisable to procure a more favorable site elsewhere and erect thereon an up-to-date plant. Belleville, Ont., was chosen. Not only has completion of same since been accomplished but first shipment of finished shells has already been made. Particulars of the new shops at Belleville are as follows: Machine shop, 150 ft. x 50 ft., steel frame and roof trusses, with walls of brick; blacksmith shop, 30 ft. x 30 ft.; woodworking shop of brick, two storeys, 22 ft. x 40 ft.: general storage building of stone, two storeys, 40 ft. x 80 ft. drive shed, frame construction, 30 ft. x 55 ft.; frame barn for horses; brick residence for watchman, and office building. The site, covering 3.6 acres, has a siding to the Canadian Northern Railroad, and constitutes ownership to a marine dock with natural rock slip, on which may be constructed later a marine railway. We are right in assuming that not only was the decision to establish a new plant, aside from that at Glenora for shellmaking, largely due to the influence of our "spoke," but the promptitude with which the project has been brought to the producing stage is equally to his credit.

Mr. Wilson is Conservative in politics and Methodist in religious creed. So far he has held no public offices, neither has he had honors or distinctions thrust upon him. One thing that all who know him well bear out—he has never been "too proud to work," and much of the success with which his shellmaking efforts are being crowned, is due to his ability to determine performance first of all, and, hence, later, direct it. On his own statement, he has never accomplished anything spectacular. In the realm of romance he has, however, played a not unimportant part, as we shall see later. His travels have been confined largely to visiting manufacturing plants in the New England States, Detroit, and Chicago; at the same time we have known him to visit the latter city on another and equally important mission.

Alton is married, the family residence being at 80 Commercial street, Belleville, Ont. His wedding to Miss Eleanor Winnifred Leeming, only daughter of Dr. John Leeming, vice-president, the American Medical Association of Chicago, took place on September 29, 1915. Needless to say he takes a pardonable pride in a little toddler at his home in the person of Margaret Eleanor Wilson.

He says nothing spectacular has been accomplished in his business career; but we have hinted at something romantic, and now take opportunity to disclose it. Dr. Leeming was cruising in his gasoline yacht on the Bay of Quinte, near Glenora, a few years ago, when misfortune overtook him in the shape of a broken flange on the exhaust manifold of his engine. He brought the damaged piece to the J. C. Wilson & Co. foundry, where a new flange was burned on, the manifold "dressed up" in keeping with the finish of the engine to which it belonged, and refitted in place. Our "Spoke" personally carried out the work, and to mark his appreciation of the service rendered, the doctor introduced Alton to the various members of his family aboard the yacht, and invited him to visit his summer home at Kingston, Ont. This he did in due course, and not infrequently thereafter, the upshot being that while apparently indissolubly wrapt up in Dr. Leeming's five sons, their pranks and recreations, he and Miss Eleanor Winnifred Leeming, the only daughter and sister, got to know each other better, with the result already indicated.

"In the shell business I have had opportunity," says Mr. Wilson, "to study human nature from the viewpoint of a mechanic through the medium of the inexperienced shell operator. Young men are best, especially those who cultivate the faculty of observation and work steadily in the interests of their fellow workers and their firm, as well as in their own interest. The quality of observation is, however, the best possible asset. To learn the "why and wherefore" of performance is worth while for a young fellow to keep always in mind. When he learns why certain things are done in connection with his own particular job, he becomes particularly well fitted for a still better appointment. Reading technical journals—advertisements as well as editorial matter, familiarizing himself with drawings, blueprints, sketches, etc., are invaluable in the general preparation for a better job. In any shop, even the most trivial details demand attention, and their proper appreciation is a prime essential. Patience is a necessary virtue, as much so as perseverance. Big things are accomplished only by those who understand their make-up details and can employ them to advantage by combination."

3,231,000 WOMEN WORKING IN BRITAIN

ALMOST a million women — exactly 988,500—have entered all kinds of positions held by men before the war began, says a London, England, despatch, and of this number nearly all—exactly 933,000—were actually substituted for men called to the front or diverted to other war activities.

This is shown in a survey of the whole movement toward women labor since the outbreak of the war, made officially by the labor department, with data down to the last two months. It shows 3,231,000 women now employed in all branches of industry and commerce or about a million more than when the war began. It is this new million of women workers one sees at every turn; on the tramways and motorbuses taking fares, in the Government offices taking the place of the men clerks, in the hotels and restaurants as waiters and cashiers, in banks and business houses, and running cinemas, theatres, and the whole range of business activities.

Some Distribution Features

Just how far this has gone, the Government has now figured out. In banking and finance, for instance, there were only 9,500 women employed before the war: now the number has increased to 46,500. In Government departments, also, the women workers have increased from 66,000 to 133,000, displacing men in all but 3,000 cases. In industrial trades the increase of women has been greatest, reaching 393,000, of which 314,000 replaced men. Another very large increase of women is in the Government ammunition works, where there were 2,000 before the war, and 117,000 now. The Government figures give the entire 117,000 as directly replacing men.

In commercial occupations, clerks in stores, offices, etc., the increase of women is 268,000, of which 264,000 replaced men. In professional occupations, connected with law, medicine, magazine and newspaper work, etc., the increase of women is 15,000, of which all have replaced men. A curious fact is that each woman has replaced about two men in hotels, cinemas, theatres, etc., the increase of women being 16,000, and the displacement of men 30,000.

Transport Service

On 'buses, trams and various kinds of transport service, women have increased 41,000, the entire number replacing that number of men. Men teachers are also largely replaced; also men on municipal transport work, the total increase of women in this line being 34,000, of which 31,000 replaced men. In farm work many men have been drawn off for the war, but few women have replaced them. The men on farms, replaced by women is given as 20,000. while the number of women farm-workers is 80,000, and the increase since the war only 500. Women nurses have increased 34,000 since the war.

Summing up the substitution of women for men, the Government statement says there has been an increase of 150,000 since last July in the number of women directly replacing men. This shows a slight check in the rate of replacement. In some trades, like clothing and textiles, women workers have decreased, probably because they were able to get better wages in the many fields now opening to them. In October 40 per cent of the textile firms reported they were unable to get all the women they required so that while the supply of women workers has increased, the demand is also increasing in many branches.

A Peace Time Problem

This replacement of men by women is introducing new elements in economic and social conditions which will have to be worked out when peace comes. The women are doing the men's work quite as well as the men, so that a new element of competition is introduced between the sexes. The women have advantage of possession of the million places, and it remains to be seen whether they will hold them, or whether there will be another displacement of women for men, when the million men come back. Many commercial houses have promised to take back the men, but whether this means displacing the women, or keeping both, it still uncertain. The labor unions are also apprehensive over the great swelling of women labor, as women workers are now about half the total strength of the unions, which are chiefly men's organizations, strong in politics and with representatives in Parliament and the Ministry. The competition between the sexes is being extended all along the economical, political and social lines.

ELECTRICAL MACHINERY OPENINGS IN CHILE

THE pre-war condition in the Chile market, in which the principal lines are electric-lighting materials and electric motors, was that, from Valparaiso to the north, the American-British manufactured article held sway, while, from and including Valparaiso to the south, German goods prevailed. The chief reason for this state of affairs is that, in the principal southern towns, the Germans own the power and light companies, and make their specifications so as to exclude British goods, and just as soon as an English article is made to fit the specification the latter is altered. There is no complete means of combating this except the setting up of competitive light and power companies, though the superiority of the English article will still enable it to hold a share of the market, says the London Times Trade Supplement.

In Northern Chile, in the nitrate works and in the mines, there is a considerable field for electric-lighting materials of all sorts and of electric motors. In the nitrate works alone there are about 140 distinct small independent power and lighting installations. As in other lines, Germans have provided cheap and inferior articles, and have in many cases got a contract where price and not quality was the prime factor. This is as might have been expected.

The manufacturer is advised to follow the same system recommended generally for Chile—that is to say, work the market with expert salesmen and demonstrators; use Spanish and metrical system catalogues and establish special agents, or use the established merchant house for the purpose of avoiding the credit danger.

Safe Practice at Blast Furnaces and Its Development-IV.

By Frederick H. Wilcox

In its efforts to increase safety in the metallurgical industries, the Bureau of Mines, Washington, D.C., has been studying the causes of accidents at blast furnace plants also methods for their prevention. This article describes the known dangers and makes suggestion of means whereby the risk of accident may be lessened or, better still, wholly avoided.

BOILER-HOUSE FORCE

ALWAYS pay attention to furnace signals for checks, slips, and shoutdowns, and be sure to follow the plant rules for taking boilers off when the furnace is shut down; failure to do so may cause an explosion. When the furnace is hanging and liable to slip, and especially when one or more checks have been blown to slip the furnace, keep away from gas burners, firing and ashpit doors, and explosion doors; the gas may flare out and burn you when the furnace slips. Do not sit on or near dust boxes, burners, or gas mains; a very small leak will let enough gas escape to "gas" you. Do not stay in any place where you can smell gas. If your work requires you to do so, have a helper with you, and be sure that your foreman knows what you are doing.

Boiler Repair Precautions

Do not go inside a boiler setting to make repairs or clean it until you have stopped with clay all gas leaks about the burners and mains near openings into the setting. If the burner or burner valve leaks and the burner can be pulled back, put a piece of sheet iron between the nose of the burner and the setting If the burner cannot be pulled back, put a blank flange in the downleg or other feasible place, unless the valve is absolutely tight. Do not enter the setting, boiler, or work on the tubes until the foreman has either locked or placed danger signs at the gas burners, blow-off valves, and stop valves at the steam leader and feed lines. Wait until the clinker and dust has been cooled off, and have someone to watch you while inside, and "spell" you off, before entering the combustion chamber. Don't stay inside when turning a hose on the walls to cool them, as the clinker is likely to spall off and expose red-hot brick dust or brick, which may make the water boil and spit and scald you. Before opening manhole covers or tubes the safety valve should be lifted; be sure the steam is entirely exhausted from the boiler.

FIG. 33. WORKMAN PLACES WRENCH CARELESSLY ON LADDER PLATFORM

FIG. 34. WRENCH FALLS AND INJURES HELPER.

Unless it is your work and you are familiar with it, do not turn gas into the boilers after a shutdown unless the foreman is present. It may explode and burn you if it is not lighted properly. Similarly, do not turn steam into a cold line or put the boiler on the main steam line unless the foreman, water tender, or head fireman is present. Never open a burner or valve with a danger sign on it. If it appears that someone has forgotten to remove danger signs when through work, report to the foreman. Don't remove the signs yourself unless directed to do so.

Opening Cold Steam Line

To open a cold-steam line proceed as follows:—First, open the valve drips; second, open the by-pass or open the stop-valve enough to warm the line slowly; third, do not open the main-line valve until you are certain the line is heated. To turn the boiler into the main steam line:—First, bring the boiler pressure to within 5 pounds of the main-line pressure; second, open the valve next to the boiler slowly; third, open the valve next to the main steam line slowly. To clean boilers: First, close all stop valves on the steam main (do not depend upon any automatic stop or non-return valve); second, close all valves between the mud drum and the blow-off main; third, if there is but one valve, put a blank flange between the valve and the boiler; fourth, close the stop valves on the feed water next the main line; fifth, close the stop valves on feed line next the boiler; sixth, place danger signs at the valves and lock them; finally, be sure the steam is entirely out of the boiler.

Gauge Glass Removal

In removing and replacing gauge glasses wear heavy goggles. When turning water into a gauge glass place a shield in front of the glass to protect yourself from glass or steam should the glass break, and turn the steam in slowly. Leaks in pipe flanges and gasket or valves should be promptly reported. Never use a hammer, chisel, or wrench on live-steam lines in an attempt to

FIG. 35. CARELESS WORKMAN STANDING INSIDE OF A CABLE BENT AROUND SNATCH BLOCK.

temporarily stop leaks. Watch your steam hose and replace it when it shows weakness. In blowing off boilers open and close the blow-off valve slowly.

In unloading ashes be sure that they are wet down, and in turning water on them do not get close enough to be burned by steam. When unloading coal, wet it down if very dry or dusty. Never use any kind of light other than an elec-

FIG. 36. WORKMAN WEARING GOGGLES WHEN GRINDING TOOL. NOTE GUARDED EMERY WHEEL.

tric light when working about dusty coal, and do not smoke. Neglect of this precaution may cause a violent dust explosion.

Riggers, Millwrights, and Handymen

Don't go on top of the furnace unless you notify the furnace foreman, so that you will not be on top when the furnace is liable to slip. Also notify your foreman so that he can send someone with you. One man should always stay where there is no gas, but in a position to watch the other man while he is inspecting or oiling. If the latter appears to be getting "gassed," the alarm should be given the stock-house or cast-house crew, and every effort made by the watcher to get the exposed man out of the gaseous place, or to keep him from falling while the crews are coming up. Do not go over the receiving hopper unless you notify the skip or bell operator not to operate the bells. Avoid making even routine examinations of hoppers and bells unless the furnace foreman knows that you are doing it and upon what particular top or furnace you are working. Repairs to explosion doors or bleeders or work inside of hoppers should never be undertaken when the wind is on. At shutdown, don't light the gas on top of the furnace until you have received the signal from the blower.

Gas Container Precautions

Before going into gas mains, scrubbers, or any enclosed gas-containing or gas-using place to make repairs or inspections, be sure that every gas connection is closed and the place cleared of gas. Familiarize yourself with the layout of gas valves, water stops, and gas mains, so that you may know where all gas connections are. Always wait until your foreman and the furnace foreman say it is safe to go in. In closing and opening sand, goggles, or slide valves watch for gas. When it is necessary to work in gaseous air, as it often is, to make some other place safe, to shut down or start up a furnace, or other reason, work in "spells," and if you feel sick or dizzy go into fresh air at once. When possible, always wear breathing apparatus or a belt and life line, both in enclosed and unenclosed gaseous places. Avoid smoking in such places.

When it is necessary to examine a chimney valve on a stove, notify the stove tender not to shut the blast off or turn the gas on. Before examining hot-blast valve slots or valves see that the gas is shut off and the chimney valve is open. Do not go inside of a hoist drum to replace or take up the hoisting cable until you have seen for yourself that the steam-stop valve is shut and the pinion blocked in the gear, or, if it is an electric hoist, that the motor switch is locked open and the gears blocked. Avoid trying to adjust the feeding or running on of cables on wrenches or hoist drums while they are in motion. Do not work on cranes, hoists, skip inclines, skip pits, and scale or lorry cars unless you know that the motor switches are locked open. When on crane runways be sure the main-line switch is open, or if the crane must be used protect yourself with track torpedoes. When pouring hot babbitt or lead warm the sockets or molds, and wear goggles to protect your eyes from splashes.

Scaffolding Precautions

Before going on scaffolding, inspect it and satisfy yourself that it is safe. Don't lean castings against scaffold uprights or pile material against them. When placing material upon scaffolds let it down carefully, don't throw it down or let it drop quickly, especially if lowering it with a winch or hoist. Place material evenly and look out for overloading. On coming down from scaffolds or platforms don't slide down ropes; use the ladders or steps provided. Never throw tools or other materials down from scaffolds unless the space below is protected with danger signs or a watcher. Do not leave bolts, rivets, tools, etc., on platforms when through work or lay them during the work where they may fall through holes or from the edge of the platform. (See Figs. 33 and 34.) Remember to use care when on ladders.

Do not attempt to tighten or adjust doors, nuts, valves, or packing glands while the blast is on, and avoid rushing repair jobs by loosening too many nuts or keybolts on blast mains, hot-blast valve seats, or heads before the blast is off. Ascertain the correct number to loosen and do not exceed that number.

Hoisting Tackle

Where hoisting tackle is used, the danger of practices such as walking near taut hoist lines, getting foul of guy lines, standing in front of snatch blocks (Fig. 35), etc., may not be apparent to laborers or members of the furnace crew who are helping. You can prevent accident by warning the men of these obscure dangers. Be sure that all hoist lines, cables, chains, tackles, and boatswain's chairs are in good shape before using them. Care should be taken in slinging a load to see that the slings are properly arranged and the load balanced and securely fastened to prevent slipping. The

FIG. 37. WORKMEN CUTTING OUT RIVETS AND USING SHIELD. NOTE THAT GOGGLES ARE BEING WORN.

part of the sling from the hook to the load should be long enough so that it makes an angle of more than 45° with the ground. Very short and flat slings are under much greater stress than ones arranged as above. In hooking on the load, watch that your hand does not get caught, and don't grab the cable above the lower sheave block.

Be sure to replace all belt, gear, machine, and engine guards, shields, and railings; they prevent accidents. Do not try to do work on electrical wires or to connect temporary lights. Defective insulation may cause a severe shock or burn, especially if you should be standing on an iron plate. Keep your tools in good shape and return all tools with burrs or mushroomed heads, cracked handles, or other defects for redressing and repairs. Avoid using pipe wrenches, defective wrenches, or a wrench that is too large for the bolt head or nut to be removed. The wrench may either slip or round off the nut. Be especially careful in working on rounded nuts and replace them with new ones at the first chance. Don't cut rivets, bolt heads, or nuts off until you have placed a shield to prevent them from flying, or have a sign or a watcher to warn men of the danger. When chipping or cleaning castings always wear goggles. (See Figs. 36 and 37.)

Regular inspection of hoists and skips, brasses, bells, sheaves, hoppers, and valves, may prevent sudden shutdowns and extra hazardous work. Members of rigging and millwright gangs, being in every part of the plant in their regular work, should know more about many obscure and not readily apparent dangers than most of the furnace force. It should be a part of their duty to report any dangerous practice or condition. There are many trivial sources of accidents, so many that no one man or committee can see them all, or, in some cases, even know that they exist until injury results.

NOTES ON HAND GRINDING

THE most common type of wheel is the ordinary straight wheel. It resembles a disc in shape, the sides are parallel and the hole rarely exceeds $2\frac{1}{4}$ ins. to $2\frac{1}{2}$ ins. diameter. Another type of wheel is that known as the tapered, bevelled, or safety shape wheel. This type has the taper or bevel on both sides, or only one side. The taper is expressed in inches per foot, starts from the face and extends to within a shotr distance of the hole. Cylinder wheels may be considered as ordinary, very wide, straight wheels with very large holes, so that the thickness of the wall is comparatively small in relation to the diameter of the wheel.

In accordance with the rulings adopted July 1, 1915, by the grinding wheel manufacturers of the United States and Canada, a cylinder wheel is 8 ins. or more outside diameter; 4 ins. or more in height, with a hole not less than 6 ins. diameter, rim thickness not exceeding 4 ins., and without inside projections. Another type of wheel is that known as the cup wheel, and may be classed as a cylinder wheel with an inside projection. This is referred to as a back. Another way of looking at it is to conceive of a cup wheel as a combination of a cylinder and a straight wheel of the same diameter.

Straight, tapered and cup wheels are mounted between flanges, while cylinder wheels are always used in a chuck. Straight wheels, tapered wheels and cup wheels should always be surrounded by a well-designed, substantial protection hood, but in the case of cylinder wheels, the retaining chuck offers sufficient protection.

Grinding is done upon the face of straight and tapered wheels, and upon the rim of cup and cylinder fheels. As straight and tapered wheels wear down unless the number of revolutions per minute is correspondingly increased, there will be a decrease in the peripheral cutting speed. With cylinder and cup wheels, however, the cutting speed remains constant throughout the life of the wheel as long as the revolutions per minute are not changed. Cup and cylinder wheels are best adapted for work which requires a straight, flat surface. Unless the cutting particles in a cup or cylinder wheel are very coarse, it will be found that the straight or tapered wheel will cut more rapidly, due to the pressure being concentrated over a small area of "narrow contact" as it is sometimes referred to.

Hand-Grinding Machines

Hand-grinding machines can be successfully driven by means of belts, direct-connected motors and silent chains, the first two being by far the most common. A combination of motor and belt-drive is proving satisfactory in a number of instances and is referred to as the group-drive method. Four, five or possibly six machines may be driven by means of belts from a piece of shafting which, in turn, is driven by means of a belt from a centrally located motor.

Which method of driving is the most economical depends entirely upon local conditions. Where it is necessary to keep machines in almost continuous operation, the group-method of driving from a central motor is found very satisfactory. However, where the work is liable to fluctuate, so that there are considerable periods during the working day when a machine is not in operation, individual direct motor drives or belt drives from individual motors, prove to be most satisfactory. When a machine must be located in a building with a very high ceiling and away from columns or girders, the direct motor drive is always specified. The manufacturers of the silent chain claim high operating efficiency, due to the impossibility of slippage between the wheel and the source of power. A number of plants, however, have not found chain drives satisfactory, due to the fact that continual attention is needed to keep the chain in repair, and wear due to dust and grit is very rapid.

Speed of Grinding Wheel

A speed of 5,000 peripheral feet per minute is recommended as the standard operating speed for vitrified and silicate straight wheels, tapered wheels, and shapes other than those known as cup and cylinder wheels which are used on bench, floor, swing-frame and other machines for rough grinding. Speeds exceeding 5,000 feet may be used upon recommendation of the wheel manufacturer, but in no case shall a speed of 6,500 peripheral feet per minute be exceeded.

A speed of 4,500 peripheral feet per minute is recommended as the standard operating speed for vitrified and silicate wheels of the cup and cylinder shape used on bench, floor, swing-frame and other machines for rough-grinding. Speeds exceeding 4,500 peripheral feet per minute may be used upon recommendation of the wheel manufacturer, but in no case shall 5,500 feet per minute be exceeded.

For elastic, vulcanite and wheels of other organic bonds, the recommendations of individual wheel manufacturers should be followed.—*Grits and Grinds.*

PAINT COATINGS THICKNESS

THE average thickness of a coating of paint for iron and steel may be one two-hundredth of an inch, states an authority on the subject. In many parts, however, the coating may easily reach a thinness of one six-hundredth of an inch. If, therefore, a paint contains particles whose smallest dimension is one four-hundredth of an inch, it is obvious that the particle will stand out in a paint coating where the thickness of the paint coating is only one six-hundredth of an inch. Many particles of pigment classed as coarse or sandy lead are considerably larger in size than the size indicated by one four-hundredth of an inch diameter, and these will project still farther through the paint film. Such coarse particles become, therefore, the weak point in the film, and corrosion may start around such particles. The paint film itself is weak at such points, as the coarse particles may not be completely encased in the oil of the film. For these reasons, concludes the authority, the superiority of a highly-oxidized red lead is really due to its fineness. It is a better pigment. Its superiority, however, lies not only in the more continuous paint film it produces, but in its producing a better working paint—a paint that flows out well but will not run, sag, or weep.

GENERALLY speaking, each metal and alloy has a particular temperature at which it possesses maximum fluidity, this temperature usually being only slightly higher than the fusing point. Metal should always be poured as soon as ready, as it deteriorates if held too long in a molten condition.

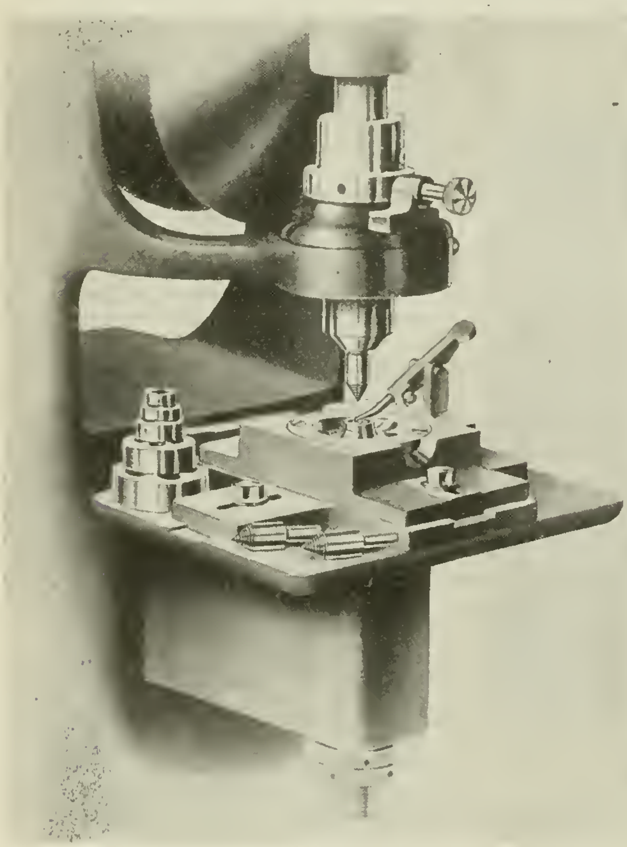
PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

DIE MUZZLING MACHINE

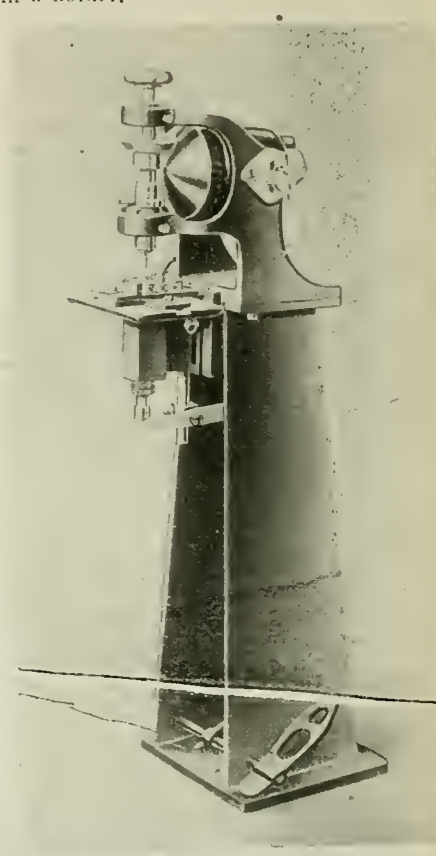
In the manufacture of threading dies of any size, one of the most difficult operations is that which is known as muzzling. This operation consists of beveling of the first two or three threads of the die in such a way as to secure a clearance so that as the die is made to work it will cut readily and without dragging. This clearance is quite similar to the clearance which is introduced on the end of a machine reamer, though the clearance is internal in the die which is contrary to that of the reamer. This operation is usually performed by hand with a small file and requires considerable skill and training on the part of the operator. The machine illustrated in the accompanying photographs, has been designed to eliminate the hand work in this particular operation, a super-helical cutter making it possible to machine the delicate threaded cutting edges without raising a burr. The cutter is made cone-shaped, the angle of the side of the cone depending on the number of threads which it is desirable to relieve or back-off; as, for example, a cone representing an angle of thirty degrees on the side will machine a clearance of about two and one-half to three threads whereas a cone of an angle of forty-five degrees on the side will form a clearance of one and one-half threads only.

The machine in the main consists of a hollow vertical spindle mounted in a frame and running on ball bearings. The chuck for holding the cutter is a split collet so that the cutters will run true under all conditions. On the spindle is mounted a friction member. This friction member is driven by means of spherical faced disc which is mounted on the armature shaft of the motor, the motor being pivoted in the frame of the machine in such a way that by tilting it, the speed of the cutting tool can be varied in order that with dies where a portion of the large diameter of the cutter is used, the speed can be reduced or increased to suit. The spindle can be locked by means of a bolt at the side or front of the machine to enable the operator to fasten the cutter securely in the chuck or collet-sleeve, a draw-bar having a knob or hand wheel at the top of the machine operating the chuck mechanism, similarly to the draw-bar used in ordinary bench lathes.



INDEX FINGER, WORK TABLE AND CUTTERS OF DIE MUZZLING MACHINE.

The table is of rectangular shape and provided with a cross-wise slot into which the fixture is secured. This fixture is primarily two slides so as to permit adjustment in all directions, making it possible not only to operate the large as well as small diameters, but also to vary the amount of clearance on the cutting edges of the die. On the upper slide of this fixture is located a pivoted finger mechanism, adjustable on this slide. This index finger locates the cutting edge of the die that is being operated on in the right relation to the cutter, and is pressed down by a spring into the openings of the die, resting with a slight tension on top, and so constructed that the die can be rotated under the finger from one cutting edge to the other. The portion of this finger which engages the die can be removed, and as many shapes and forms of fingers as may be necessary can be made and applied by inserting in a holder.



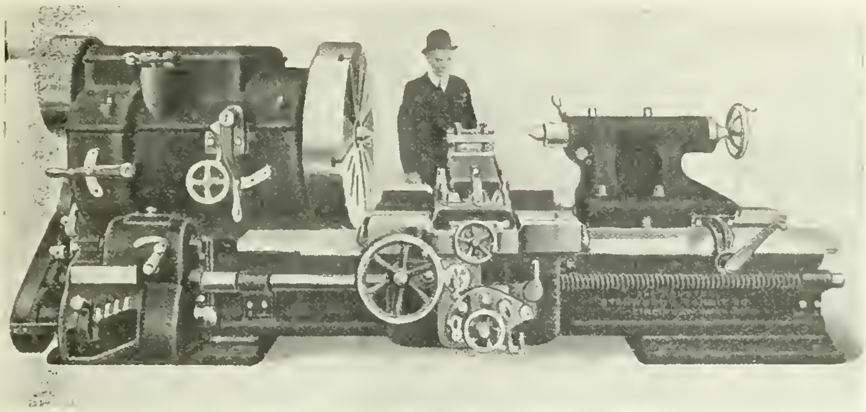
DIE MUZZLING MACHINE.

The table is raised and lowered by means of adjustable foot treadle mechanism located at the lower right hand side of the pedestal. If necessary, a safety spring device can be introduced in this connection between the foot treadle and the table so that regardless of the pressure applied by the operator on the foot treadle, the pressure exerted on the table spindle will be uniform.

Any make of motor not exceeding 6 in. in diameter can be applied to this machine, 1-16 h.p. 1700 R.P.M. being ample for the operation. A switch is conveniently located for starting and stopping the machine. Cord with attachment plug so that the machine can be run from the ordinary lamp socket is also furnished. The Anderson Die Machine Co., Bridgeport, Conn., are the makers of this machine.

LARGE HEAVY DUTY LATHES

THE heavy and constant demand for lathes during the last two years which was largely concentrated on medium sizes when munitions orders were first undertaken, has of late been tending toward larger machines in line with more recent munitions contracts, and requirements in this respect have been met by a line of heavy duty lathes with a nominal swing of from 30 in. to 42 in. the product of Houston Stanwood & Gamble Co., Cincinnati.



TRIPLE-GEARED HEAVY DUTY LATHE WITH SINGLE PULLEY SELECTIVE SPEED HEADSTOCK.

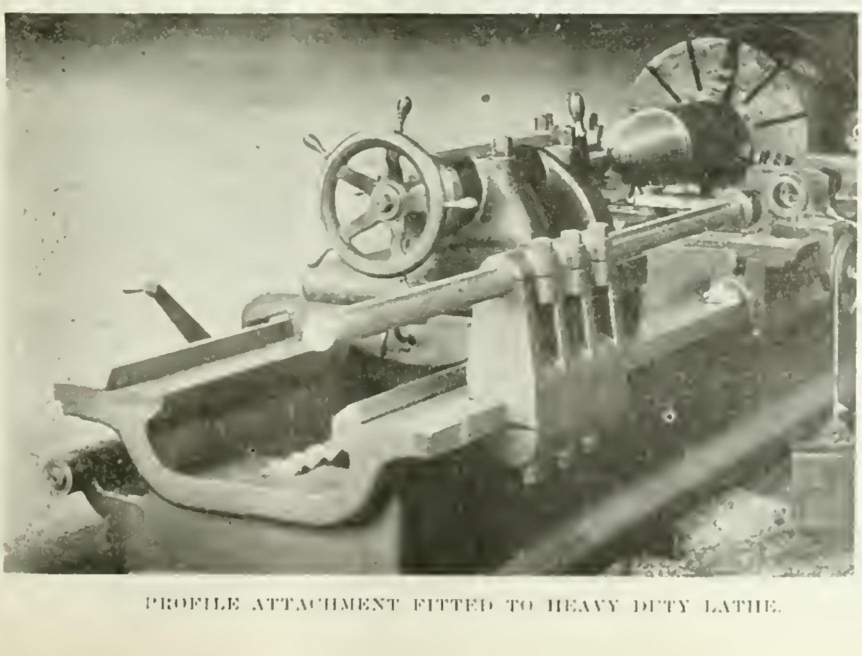
Four distinct machines constitute this series, viz., 30 in. and 36 in. double back-geared, swinging 34½ in. and 40½ in. respectively over vees, and 36 in. and 42 in. triple geared, swinging 41 in. and 46½ in. respectively, over vees.

The general lines of the headstock are the same in the several sizes, the front and rear walls being carried up to the centre line of the leaving no exposed gears on shafts even in the cone-driven type. A feature of the design is the arranging of all the principal driving elements and operating levers below the centre line in identical manner so that a cone headstock can be changed to a selective speed headstock at any time with discard of the cone only.

All speed gear changes are obtained through the levers and hand wheel on front of the headstock the handwheel appearing on the triple geared lathes only. The horizontal lever operates the back gears, and the vertical lever operates a jaw clutch between the face gear and cone pulley, the conventional spring plunger operated by hand having been discarded for reasons of safety and efficiency.

Double back geared lathes with selective speed headstock have twelve speed changes, and triple geared lathes of the same style have fifteen, which with a two speed countershaft provides 24 and 30 speeds respectively. Both spindle and back shafts are of high carbon steel, accurately ground, with large hole through spindle, and all bearings are bronze bushed. Special attention has been given to lubrication. All gears in motor-driven and selective speed lathes running in oil with a splash system. Wrought or cast steel is used for all gears except a few large gears subject to low pressures, these being of steel mixture, while all proportions are designed for loads considerably in excess of normal.

The design of the bed adopted is in line with most advanced practice, the front vee having a large bearing surface on top, with the front and rear bearing surfaces so disposed as to constitute a long narrow guide for the carriage. Gibs at the front of and underneath the front vee, and also underneath the rear vee are adjustable and prevent lifting or cocking of the carriage. The front vee is lubricated by means of atmospherically sealed oil pockets inside the carriage, shear wipers being also fitted to both front and rear vees.



PROFILE ATTACHMENT FITTED TO HEAVY DUTY LATHE.

Four stud tool rest is ordinarily furnished, and the compound rest has a special square base avoiding overhang of the top slide. Tapered gibs are fitted to both upper and lower slides, and the compound rest is graduated in such a manner that the graduations may be read from above.

The double wall apron is tongued to the carriage and carries all steel gears, while the rack and certain parts are heat treated; bronze bushings are employed where steel would run on steel otherwise. Two positive clutches are employed for carriage feeds, preventing loss of capacity through slippage of frictions, while a safety shearing pin carried by two discs on the front of the apron prevents dangerous overload on the mechanism. Forty-eight changes of feeds or threads are provided, all gears from spindle to apron being steel, the feed mechanism being simple and entirely accessible.

The tailstock is secured in position by four large hold-down bolts with heavy clamps, which are located toward headstock end of tailstock. A retaining pawl with rack, and gear traverse are arranged therewith, while the locking clamp or spindle does not destroy alignment.

Motor drive by either d.c. or a.c. current is provided for, the selective speed type of headstock being used when constant speed motors are employed. These lathes are built in any length of bed from 12 ft. up, and included in the regular equipment are compound rest, steady rest, large face plate (also small face plate for double back geared lathes), double friction countershaft for belt-driven lathe, centres and wrenches. The 36 in. double geared machine weighs 18,000 lbs. and with triple gear 24,000 lbs. the full line of this maker's product being marketed in Canada by the Rudel-Belnap Machinery Co.

First-class tool steel is now being made at the Lisvensky works in the Urals, Russia, and preparations are being made to increase the output after the war. This commodity was formerly imported in large quantities.

Took Her Cue from Pa.—A little girl, being invited to a children's party, was cautioned by her mother how to behave, and that when the cake came round the first time she should say, "Yes, please," and take a piece; also the second time to do the same, but at the third time of asking she was to refuse any more cake and say, "No, thank you." The next morning the mother asked her little girl how she got on at the party. "Well, mother, I did as you told me; but they brought the cake round a fourth time, and you didn't tell me what to say. So I looked at the lady and said, 'Take the damned thing away' —like pa says."

Vol. XVII. FEBRUARY 22, 1917 No 8.

BUSINESS OUTLOOK CONTINUES FAVORABLE

ALTHOUGH the immediate outlook continues somewhat unsettled, the opinion is becoming more generally held that even should the United States enter the war arena on the side of the Allies, the industrial situation in Canada will be but slightly affected, if at all. At least, while the war lasts, and regardless of whether only preparedness or entry into the war be the ultimate outcome across the line, capacity business is assured for Canadian steel producers. For this reason the latter are likely to continue to enjoy for a good many months to come the activity and in large measure the prosperity which they experienced during 1916. Extreme and violent declines in stocks are thus unlikely, although fluctuations, with a steady downward tendency, will occur more so than in normal times on account of war-engendered business sensitiveness.

Steel Production Earnings

It is extremely doubtful if steel production earnings and therefore profits for the first quarter of this new year will be as great as anticipated some few months ago, owing to the curtailment of output. In this regard the situation is not particularly bright for immediate improvement, owing to transportation difficulties, the recent severe weather having still further restricted the movement of cars on the railways, and in consequence, offset the advantages expected to be derived from the transfer of passenger train motive power and crews to that of freight haulage.

Conservative Distribution of Profits

The more or less conservative policy being pursued by our various steel companies relative to dividend distributions is such as to commend itself not only to our citizens generally, but to the investing public as well. While big profits were undoubtedly earned during the first eighteen months or so of the war, it is only reasonable to expect that due to keener prices now in evidence the various executives concerned feel it incumbent upon them to get rid of the many heavy indebtednesses incurred, and that were as a matter of course incidental to the establishment and development of an industry so gigantic as that of steel manufacture in a comparatively new country. The opportunity to do so is for the first time available, and there is every indication that it will be fully taken advantage of. In the ensuing twelve months, or for the remaining period of the war, profits arising from steel contracts for munitions are likely to be a shade, at least, under those realizable from normal peace-time business, a circumstance which serves to indicate that further opportunity to accumulate cash reserves on a big scale will not be available. By adopting the policy outlined, not only will the old-time millstones of heavy indebtedness be cut loose, but bank balances of the most substantial proportions and the physical condition of plants and equipments be enhanced in value as operating assets, necessities, individual and in combination to take full advantage of the many peacetime business offerings which are certain to develop.

Railroad Transportation Causing Anxiety

Both Canada and the United States for many months now have been experiencing big business in a manufacturing sense, same having, from foundation to superstructure, steel as the main constituent. Troubles inherent to it have been successfully surmounted. Not so, however, as regards that outside its pale, yet accessory—the matter of transportation of material. In a word, our manufacturers have taken the overload of big business comfortably, while our railroads, so to speak, have gone to pieces under it. Preceding and immediately following the outbreak of the war, our railroads more than any other section of our commercial and industrial enterprise set the pace for retrenchment in expenditures, and as each succeeding month unfolded, the disposition to maintain a like attitude appears to have been still further encouraged. Some three years have elapsed, as a consequence it is only reasonable to assume that rolling stock in any quantity is far from available to meet the abnormal traffic now in evidence, and that additions to it, aside altogether from the upkeep and overhauling of that existent, are financially burdensome with material and labor costs at their present figures.

Railroad Buying Long Overdue

That our railroads will have to come into the market sooner or later with very substantial orders for equipment of every kind is of course understood, because otherwise that species of transportation will go from bad to worse, and meantime it would almost appear that we are now making contact with the latter. There is a problem here: Can our railroads pay the price for material on existing freight rates? We think not, even although they have been to a very great extent responsible for the present highly unsatisfactory state of affairs. We are of opinion that steel for much new rolling stock, also steel rails in quantity will yet have to be purchased at prices little, if any, below those now ruling.

Steel for Shipbuilding

High steel prices are sure to prevail for the duration of the war, and on some products, particularly plates, for a considerable time afterwards. The demand for ship sections and plates is far in excess of present production, the mills having their output in various forms sold for the whole of this year. Prices, consequently, are very high, and the crest of the upward movement is not in sight. The ships lost during the war will have to be replaced; the outlook in the shipbuilding industry is thus exceptionally bright. The large number of ships now being built in the United States and Canada is largely responsible for the tight situation in the plates and shapes market. Canadian shipbuilders are participating to the fullest extent in the construction of new tonnage, the yards on both coasts and on our inland lakes being full up with orders. Notwithstanding the high costs of plates this activity is sure to continue until the shortage of tonnage has been well met. Getting plates, even at any price, is quite a problem.

INDUSTRIAL NOTABILITIES

PERCY FORD-SMITH, president and general manager, Ford-Smith Machine Co., Hamilton, Ont., is of English birth and parentage, having been born at Wolverhampton, Aug. 10, 1881, his ancestors on both sides of the family having been English as far back as records are available. After graduating from high school he attended the Royal Technical Institute, Manchester, and served an apprenticeship of seven years with Smith and Coventry, Ltd., Manchester, one of the principal machine-tool firms in Great Britain. Four years of this period were spent in the shops, and three years in the drafting-room, the experience gained thereby being supplemented by three years in the United States, during which time Mr. Ford-Smith was employed in several machine-tool plants in various capacities.

PERCY FORD SMITH.

Mr. Ford-Smith returned to England at the expiry of this period, under a four-year contract with a prominent machine-tool concern, during which time he modernized their plant in line with the best practice then extant. He then came to Canada and became chief draftsman with the London Machine Tool Co., Hamilton, leaving them to organize the Ford-Smith Machine Co., Ltd.

The building of grinding machines and special machinery occupied his attention until the outbreak of hostilities, since when special applications of his machines to munitions production have been a feature of the business.

Since the beginning of the war he has devoted much of his time to recruiting, and holds a lieutenancy in the Canadian Engineers.

Mr. Ford-Smith is Independent in politics, and in religion is Church of England. He married Olive Spengler, daughter of Prof. A. Spengler, late of Western Reserve University, Cleveland, O., and has a family of three children.

The General Market Condition and Tendency

THE congestion of freight at railroad terminals continues to cause great inconvenience to manufacturers and merchants in the matters of shortage of fuel and delay in receipts of their raw and finished materials. The railways, owing to shortage of labor, cars and motive power, seem unable to cope with the situation, which is serious, notwithstanding the extraordinary efforts now being made to relieve the congestion. The severe weather has, of course, made conditions more difficult to deal with, and for the same reason the situation is more acute. Manufacturing operations are being curtailed, which is unfortunate, particularly at a time when trade is unusually active. Although there has been no important change in the international situation, developments are being watched with considerable interest in business circles. Conditions as they effect the steel mills and foundries in this district show no improvement and production is being curtailed owing to the continued shortage of coke and pig-iron. These materials are becoming more difficult to obtain as conditions in the United States are, if anything, worse. The natural result will be higher prices on steel products. Plates have already advanced, while higher prices on black sheets, among other products, may be looked for at an early date. There are no quotations obtainable on domestic foundry pig-iron, as this material is still off the market. Prices on copper and other ingot metals, with the single exception of tin, are holding firm. Lead has advanced, due to a scarcity of spot supplies. The international situation is a controlling factor in the metal markets and the possibility of increased demand is tending to hold prices firm. The machine tool trade continues quiet, awaiting developments. Prices on machine tools have an upward trend and deliveries are, if anything, a little better. Prices of copper and brass scrap have advanced, and the market is very firm for old materials of every kind.

Montreal, Que., Feb. 19, 1917.—The outstanding feature of the industrial situation is the freight congestion, which is creating serious conditions in production and transportation circles. The non-delivery of coke and coal, together with the scarcity of other raw material, has forced curtailment upon the general output, with the partial shut down of several furnaces and mills. Unsettled conditions across the line tend toward still further difficulties, with little prospect of early relief.

Pig Iron

The abnormal demand for pig iron, more especially Bessemer and basic, together with the curtailment of production caused by the lack of raw materials, is creating a serious situation, and unless some relief is given to the freight congestion, the stoppage of mills may greatly affect early future conditions. Latest reports from the Pittsburg district indicate a very strong market on advancing prices; Bessemer and basic being $1 a ton higher than last week.

Steel

Throughout the entire steel trade the situation is featured by the pronounced shortage of fuel; this factor having a serious effect upon production, as many mills have been forced to curtail their output owing to lack of raw material. The tie-up of export shipping has caused large quantities of material to accumulate on the seaboard, and embargoes are numerous on certain goods going East. The shortage of cars is quite serious, but the lack of men and motive power is the chief reason for present conditions; prospects for early relief are not bright, and the outlook seems to indicate still more serious developments. With conditions tending to increased difficulties, both as regards production and transportation, early advances are anticipated. The situation in Bessemer billets and sheet bars is more acute, Bessemer pig having advanced $1 per ton over that quoted at Pittsburg last week. No relief is evident in ferro-alloys, as the supply is still scarce; quotations are withdrawn and higher prices will likely prevail. The production of plates is still below the demands, and mills are unable to keep pace with trade requirements, which are daily increasing; car inquiries are lighter, but ship plates are in exceptional demand. With the sheet mills filled to capacity and some producers withdrawing quotations, higher prices seem imminent. Quotations on manufactured steel are advancing, the discount on pipe having been reduced two points during the week. Increased activities are developing in wire and wire products, and more pressure is being placed on producers for future requirements.

High Speed Steel

Political developments in the States may create an increased demand for high speed steel, and dealers here anticipate a stronger market should war be declared. Prices at present are firm at from $2.50 to $2.75 per lb.

Metals

The difficulty of obtaining delivery on material has had a strengthening effect generally, but with the obvious discounting of the submarine menace, a more even tone is apparent. Copper is higher and active. Tin is lower, following safe arrivals of shipments. Spelter is quiet, but unchanged. Lead is strong, due to scarcity of spot supply. Antimony is weaker, but developing firmness.

Copper.—Prevailing conditions are still retaining copper in a strong position, but the near future may see changes, inasmuch as export metal is accumulating at various points owing to tie up of ocean bottoms. Should submarine activities prevent the export of copper, the available supply may result in a weaker market, but little is expected to be offered for sale owing to its being under contract for the British Government. Advances on the New York market range from 1c on lake to 2½c on castings. Owing to the non-delivery of metal and the freight congestion, local dealers are asking 40c for lake and electro, and 39c for castings, this representing an advance on the week of 3½c per lb.

Tin.—The submarine scare having decreased somewhat, the easier tone is reflected in the gradual return to conditions of a few weeks ago, and lower quotations are more general, but no sharp decline is expected, as the marine risks are not yet entirely removed. Both London and New York markets are easier, and quotations are lower, the New York decline being 4c, or a current quotation of 50c per lb. The local market has become more accessible on a decline of 5c, the nominal quotation being 51c per lb.

Spelter.—Activity in spelter is confined to the selling of small lots, buyers not showing any great interest in large orders. Like other metals, spelter is affected by existing conditions. The market here remains unchanged, with prices firm at 15c per lb.

Lead.—The apparent scarcity of spot metal continues to force prices upwards. The advance has resulted from the urgent requirements of certain consumers and their willingness to pay exceptional prices for supplies. The freight situation is chiefly responsible for the advance, and early relief seems unlikely. New York independents are asking as high as 10¼c per lb. Local dealers are dubious about prices, but quote the nominal figure of 12½c.

Antimony.—Activity is not pronounced, demand being light. The supply is not very great, however, and any heavy inquiry would result in higher prices. Quotations on the New York market are 5c lower than last week, the price quoted being 30c per lb.

The local situation has become easier, and dealers have declined to 30c, this being 7c lower than last week.

Aluminum.—The market is unchanged and quotations remain firm at 70c per lb.

Machine Tools and Supplies

The market for machine tools has shown some improvement during the past few weeks, more especially for additions to 4.5-inch shell equipment. The changes called for by the specifications entail increased work on the interior, and inquiries for boring machines have increased. Partly used machinery from the States, which a few weeks ago appeared to be featuring the Canadian situation, has not been so freely offered, owing to possible developments. Higher prices would naturally follow a war declaration, with increased difficulty in obtaining delivery from American machine tool makers.

Scrap.—The market is in an unsettled condition, but comparatively firm. Copper, lead and zinc were higher earlier in the week, but the general market continues steady, with no important features outside of a stronger undertone, which may be reflected in advances upon early developments.

Toronto, Ont. Feb. 20.—The freight situation continues to cause considerable anxiety to manufacturers in spite of the extraordinary efforts that have been and are being made to relieve the congestion. Not only is the shortage of fuel causing much inconvenience, but shipments of raw materials and partially manufactured goods are being held up and so restricting manufacturing operations.

Steel

There is no evidence as yet of any improvement in the steel situation notwithstanding the strenuous efforts that are being made to break the blockade at Buffalo. There has been a heavier movement of coal during the week, but the shortage of fuel and pig iron still continues to be the dominant factor in the iron and steel trades. Mills in Canada depending upon the States for supplies of coke, and to some extent for pig iron, are confronted with conditions which are steadily getting worse owing to the embargoes on the railways in the U.S. restricting the movement of cars. No immediate relief is in sight, although with milder weather becoming imminent, the railways will have a better chance to cope with the situation. The mills already well sold up, are getting further behind on deliveries due to curtailed production and increase in demand. The steel market is thus very strong and higher prices on steel products are inevitable. Plates have already made a further advance of 25 cents, and are now quoted as follows; ¼ in. and larger $6; heads $6.35; tank plates $5.85. per 100 lbs. The large increase in ship construction has intensified the demand for plates, but owing to the sold-up condition of the mills, deliveries are very slow while plates for early deliveries continue to bring extremely high prices. Makers of boiler tubes, have practically their entire output sold up over the remainder of the year and prices are very firm with an upward tendency. Prices of iron and steel bars continue very firm, and a further advance is likely.

The demand for high-speed tool steel continues heavy, and it is still a difficult matter to obtain supplies of this material from England or the States. There is very little steel coming from Sheffield owing to the heavy requirements of the British Government. Some tool steel can be obtained from U.S. makers, but deliveries are slow and quantities much below requirements. Domestic tool steels are finding a ready sale at firm prices. There is thus very little change in the high speed steel situation and prices are practically the same, ranging from $2.50 to $3 per pound according to quality. Carbon steels are advancing in price.

Production of sheets continues to decline owing to short deliveries of coal and sheet bars. The situation is serious as some mills will have to close down unless supplies of coal come forward more freely. The leading interest in the States announces that it has withdrawn from the market on all grades of sheets for shipment up to July 1, its product being sold up; as a result prices are very firm and will go higher. Galvanized sheets will doubtless be affected for the above reason and also on account of the scarcity and high cost of acids.

Producers of iron and steel in the States are suffering severely from tre reduction in freight movements. The congestion of freight at the seaboard has resulted in embargoes on practically all the railways affecting the entire country particularly in the East. The production of both iron and steel is greatly restricted and the situation is getting daily more acute. Prices are tending upwards in all directions, and the prevailing high cost of pig iron will affect prices of finished materials.

Pig Iron

There is no improvement in the pig iron situation, and the market is upset. The coke shortage in the U.S., due to lack of cars and motive power has resulted in many furnaces being banked. There is therefore a shortage of pig iron which is seriously affecting the steel mills. Foundries are also severely handicapped and in some cases have practically closed down. Canadian foundry pig iron continues off the market owing to the shortage of coke and no prices are being quoted.

Scrap

Prices on all old materials are very firm. Quotations on copper and brass scrap are about 2 cents higher in sympathy with the increased cost of ingot metals. All steel scraps are very firm, but unchanged with the exception of low phosphorous steel which has advanced 4 cents, although the price is really nominal as this material is practically off the market meantime. Scrap leads have advanced, and zinc is also a shade higher. Stocks of machinery scrap iron are light owing to a heavy demand, due to the scarcity of pig iron.

Machine Tools

The machine tool market is quiet and may be said to be awaiting developments. The international situation is a factor of considerable importance, while there is also the placing of further shell contracts to be considered. Business now consists principally of single tools for munitions plants as replacements, or to increase production. There is no indication of a decline in prices, the tendency being all the other way. United States builders of special railroad shop tools have raised their prices 10 per cent. which is the first advance for some time.

Supplies

The demand for machine shop supplies continues active with a general tendency towards higher prices. Lead sheets have advanced 1½c per pound, and lead wool 1c, the latter being quoted at 14c per pound. Gasoline and coal oil are in good demand with prices very firm. Higher prices on gasoline are looked for in the near future. Linseed oil is very high in price, being now quoted at $1.40 for raw, and $1.43 for boiled oil. Putty has advanced 20c per 100 pounds.

Metals

The international situation continues to affect the metal markets and is tending to make prices firmer in anticipation of increased demand. The submarine situation is also affecting the markets, but not to any material extent as the opinion is generally held that the submarine operations will not interfere with shipments of metals to an extent sufficient to cause any serious delay or loss of cargoes.

Copper.—Quotations on copper continue nominal, there being very little spot metal for sale to form a basis for prices. Producers are falling behind in shipments while some consumers are suffering from a shortage of copper and are compelled to pay very high prices. Copper is unchanged locally at 38 cents per pound.

Tin.—The market is easier due to arrivals in New York of large amounts of tin, and prices are a shade lower. There is also less fear of metal being lost through submarine operations. Tin has declined 2 cents locally, but is entirely nominal at 56 cents per pound.

Spelter.—The market is quiet and unchanged, but there is a firm undertone. Production is being seriously interfered with owing to the cold weather and another strengthening feature is the high cost of ore. Local price unchanged at 13½ cents per pound.

Lead.—A tight situation has developed in the market due to the scarcity of lead as a result of the freight congestion. The "Trust" is still quoting 8.50c, but independents have jumped the price up to 10c and 10.25c, New York, for spot metal. Lead has advanced 1c locally, and is now quoted at 12c per pound.

Antimony.—The market is firmer, but quotations are unchanged in the meantime. Considerable interest has been aroused by the refusal of leading sellers of antimony to issue quotations on future shipments from China. It is understood that most of the producers there are sold up completely until April, and unless they could obtain assurance of freight space they would not offer any further tonnages. Local price 35c per pound.

Aluminum.—The market continues firm and unchanged at 68c per pound.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

TRADE INCREASE WITH BRITAIN

A LARGE increase in imports from Canada is a feature of British foreign trade returns for 1916, according to a report received by the Trade and Commerce Department ,Ottawa, from Commissioner Harrison Watson, of London.

"The immediate impression created by the returns," says Mr. Watson. "is one of wonder that it has been possible for the United Kingdom to carry on a trade of such magnitude under every variety of adverse circumstances, and its accomplishment forms the highest tribute to Britain's command of the seas and her unimpaired financial strength and ability. While the total foreign trade for 1916 attained the colossal value of $7,766,536,965, an increase of no less than $1,087,400,000 over the previous year, it is satisfactory to be able to record that the growth in British exports was considerably in excess of the increase of imports. Whereas the increase in imports was 10.2 per cent., the advance in exports was 31.6 per cent."

Mr. Watson attributes the reduction in the adverse balance of trade, which commenced to be an alarming feature of British trade returns shortly after the outbreak of war, to the restriction of imports, and states: "It is difficult to see how imports can be further curtailed if the wants of the population are to be adequately met."

He gives praise to the British industrial system, which, though largely occupied with munition making, has been able to accelerate its production of commercial exports as well. As regards trade with Canada, he states: "It is satisfactory to see that in almost every item there has been a large and in some cases remarkable increase in the quantities received from Canada, the advance in valuation being proportionately much greater owing to the heavy rise in prices which has taken place."

Among the articles of import from the Dominion are: Wheat, $76,000,000; flour, $18,000,000; barley, $9,000,000; maize, $6,000,000; bacon, $37,000,000; cheese, $37,100,000. The export of bacon has nearly doubled as compared with 1915. Canadian lumber exports are growing also, and now constitute 20 per cent. of the whole total, as compared with 15 per cent. of former years.

Aggregate Trade

The aggregate trade of Canada during the period ended November, 1916, amounted to $2,060,561,658, of which $1,269,928,215 represented exports and $790,573,443 imports. Canada thus enjoyed in the period a favorable balance of trade of $479,354,772. Imports into Canada from the United Kingdom amounted to $118,154,745 and from the United States merchandise to the value of $572,730,816. Included in the exports of the Dominion were goods to the value of $690,538,735, to the United Kingdom, and merchandise to the value of $291,069,070, which went to the United States. Imports of coin and bullion amounted to $46,170,398, while exports of the same totalled $196,422,615, most of which went to the United States. Some indication of the expansion of trade may be gathered from the fact that in the 12 months ending November, 1915, the aggregate trade of the country was $1,175,216,733, of which $448,158,536 represented imports and $727,058,197 represented exports.

EQUIPMENT NEEDS OF MESOPOTAMIA RAILROAD

THE Persian Gulf & Mesopotamia Development Co., which is now surveying a line from Bagdad, and which is connected with interests concerned in the management of important railroads in India, has, through J. S. Popper, New York City, issued a long list of equipment requirements for the railway and

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa. British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—H. R. Poussette, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H Ross, Stock Exchange Building, Melbourne. Cable address. Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—Acting Trade Commissioner, Lonja del Commercio, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—G. B. Johnson, P. O. Box 109, Yokohoma. Cable address. Canadian.

HOLLAND—Acting Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address. Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrivskaya. Ploshch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent. Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address. Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street. Bristol. Cable address, Canadian. J. E. Ray, Central House. Birmingham. Cable address, Canadian. J. Forsyth Smith, 27-28 Pearl Building, East Paradise, Leeds. Cable address. Canadian. F. A. C. Bickerdike, Canada Chambers, 36 Spring Gardens, Manchester. Cable address. Cantracom. J. T. Lithgow, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.

SPECIAL TRADE COMMISSIONER—LUMBER

H. R. McMillan, visiting Europe, Africa, Australasia and the Orient.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin, Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau. Bahamas.

NORWAY AND DENMARK—C. E. Sontum Grubbeged No. 4, Christiania, Norway. Cable address. Sontums.

CANADIAN HIGH COMMISSIONER'S OFFICE

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

is asking various car and locomotive builders if they can meet the required deliveries. The equipment will be taken in installments over a period from September, 1917, to 1921, and includes the following:

Three hundred and thirteen passenger locomotives, 863 goods locomotives, 78 locomotives for mixed passenger and goods trains.

Four saloon and state cars, 85 reserved carriages, 11 dining cars, 75 first class carriages, 145 composite first and second carriages, 152 composite, first, second and third class carriages, 45 other carriages.

Fifty-seven second class carriages, 126 intermediate class carriages, 221 composite and intermediate and third class carriages. Five hundred third class without brakes, 653 third class ambulance carriages, 17 third class ambulance carriages with brakes, 80 third class and postal carriages.

Three hundred and eighteen passesger brake vans, 19 brake vans with postal compartment, 4 postal vans, 54 carriage brakes, 150 horse boxes, 44 luggage vans, 164 miscellaneous, 18 stores vans.

Twelve thousand two hundred and eighty-two covered goods wagons, 2,578 high-sided wagons, 553 low-sided wagons, 8 cattle trucks, 12 platform wagons, 64 powder vans, 242 timber trucks. 267 bolster trucks, 240 ballast wagons. 399 brake vans (all uses).

Ninety-two oil tanks, 79 water tanks, 35 gas holders, 68 cranes, 16 miscellaneous items, special work, etc., 232,000 tons of 65- pound steel rail, 4,000,000 creosoted pine ties.

THE EXPORT ASSOCIATION OF CANADA

THE Export Association of Canada Montreal, in its annual report, urges upon the business community of Canada the necessary for the immediate study of the economic problems which Canada must face after the war. Over 600 Canadian factories are completly utilized with munitions orders, and 400,000 Canadian workers are making war equipment. During the year the association placed with Canadian manufacturers 871 orders, totalling in value $734,000. An attempt was made to organize a campaign in Siberia, but the project was abandoned owing to the rigid embargo placed upon traffic at the port of Vladivostock.. The cost of operation during the year was, roundly, $34,000. The trading profits amounted to about $19,000, leaving a deficit of $15,000. The deficit has been partly offset by subscriptions to stock amounting to $7,500. The present available capital for operating is $37,621.83. The officers for the new year are: President, J. H. Sherrard; vice-president, R. Montague Davy; executive committee, J. H. Sherrard, R. Montague Davy, R. H. McMaster, R. E. Thorne and Paul Joubert.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Amherst, N.S.—The Maritime Coal, Railway & Power Co., contemplate purchasing pumps, motors and electrical equipment.

Vancouver, B.C. — The Maritime Motor Co., has been formed here to manufacture a special type of mining and logging locomotive, driven by gasoline engine.

Toronto, Ont.—The Queen City Foundry Co. plant on Cherry street, was gutted by fire on Monday morning. All the equipment was destroyed and also the patterns. The loss is estimated at $60,000 which is only partially covered by insurance.

Kitchener, Ont. — V. O. Phillips & Sons, of this city, have made application for a permit to erect a new addition, 60 by 100 feet, to the plant of the Twin City Oil Co., for the purpose of manufacturing a visible gasoline pump having purchased the Canadian rights.

Toronto, Ont.—It is reported that the Nathan Manufacturing Co. of New York may establish a factory in Canada for making locomotive accessories. O. Best manager of this concern's New York factory is investigating business conditions in Canada with the above object in view.

Lindsay, Ont.—Flavelle's Ltd., cold storage building will be re-built. The new plant will comprise a creamery and egg house having a total refrigeration capacity of about 25,000 cub. feet. The Canadian Ice Machine Co., Toronto are supplying the new equipment which will consist of brine coolers, condensers and over 20,000 feet of 2 in., ammonia piping for the cooling rooms.

The British American Nickel Corporation are having plans prepared for the first unit of a large nickel refinery to be built at Murray Mine about three miles from Sudbury, Ont. The initial unit will cost approximately $1,500,000 and will consist of two blast furnaces, three converters and power plant. There will be buildings comprising the smelter building, machine and blacksmith shops, power house, etc. The buildings will be of brick and steel construction requiring about 2500 tons of steel. The company propose using about 5000 h.p. hydro-electric power, and all the machinery will be driven by electric motors. The power plant equipment will consist of two 30,000 cub. ft. 12 lbs. pressure air compressors for the convertors, two blowers, of 30,000 cub. ft. capacity at 40 ounces pressure, for the blast furnaces, motor generators, switchboard, 1000 h.p. water tube boilers, pumps, etc. The construction plant is being assembled, and building will start in the early spring. F. T. Brule, Royal Bank Building, Toronto, is the engineer, for the company and is preparing the plans.

The Port Arthur Pulp and Paper Co., propose building a mill probably at Port Arthur, Ont., but in the meantime the work is being held up. The plans call for a total expenditure of $2,000,000 but the initial unit will cost in the neighborhood of $500,000. The mill will have a daily capacity of 50 tons of sulphite pulp, but at a later date a book paper mill will be erected. The buildings will be of brick and reinforced concrete construction with steel roof trusses. About 1000 h.p. of electrical energy will be required for driving the machinery, and three 375 h.p. boilers will be installed for steam heating, also for manufacturing purposes. Other equipment required will include wood and steel tanks, and storage vats, electrical equipment and log conveying machinery. T. H. Weldon and S. F. Duncan of the Provincial Paper Mills, Toronto, are interested, and A. G. Pounsford is general manager.

ELECTRICAL

Windsor, Ont.—Officials of the Canadian Steel Corporation have made application to the Ontario Hydro-Electric Commission for a supply of Niagara power, according to Chairman Shepherd, of the Windsor Hydro-Electric Commission.

Chatham, Ont.—A proposition will probably be endorsed by the Provincial Hydro Commission whereby it is proposed that the city purchase the Electric Department of the Chatham Gas Co. for $115,000, thus removing competition with Hydro.

Toronto, Ont.—Scarborough Township Council, at their meeting on February 12, passed a by-law authorizing the issue of debentures to the value of $18,500 to finance the installation of a Hydro-Electric system in that part of the township extending from the limit of the City of Toronto to the town of Agincourt.

MUNICIPAL

Chatham, Ont.—It is proposed to give $5,500 by way of a bonus to the Libby, McNeill & Libby Co., of Canada.

Grimsby, Ont.—The ratepayers have granted a loan of $6,000 to the Metal Craft Co., which will erect a plant there.

Montreal, Que.—The bids received on Feb. 12 for street cleaning machinery, amounting to $160,000, have been rejected. New tenders will be called on Feb. 26. The equipment required consists of twenty flushers and sweepers for the street cleaning department.

Hamilton, Ont.—The Board of Control contemplate the purchase of a motor driven street flusher and an aerial truck.

Midland, Ont.—A by-law will be submitted to the ratepayers on March 3 to authorize a $25,000 bonus to the Midland Dry Dock Co.

Montreal, Que.—According to an order issued by the Provincial Board of Health, the towns of Ste. Anne de Bellevue, Pointe Claire and Dorval must instal filters, as the water in Lake St. Louis is unfit to drink.

Horton Township, Ont. — A by-law will be voted on by the ratepayers on March 2, to authorize a power company, of which M. T. O'Brien is at the head, to erect transmission lines in the township.

Gleichen, Alta.—A by-law will probably be submitted to the ratepayers to ascertain their opinion on the purchase of the local electric light plant, now privately owned. The proprietor offers the plant for $6,000, and will accept the town's debentures for the amount.

Winnipeg, Man.—The Board of Control have decided to replace all rigs in the waterworks department by motor trucks not later than June 1. Tenders are to be at once called for three to three and a half-ton trucks, also for five-ton trucks. These will be fitted with automatic tips and knives for snow plowing.

Toronto, Ont.—Tenders have been received for the supply of cast iron pipe, water meters, hydrants and valves for the proposed waterworks system for York Township. The firms tendering included the National Iron Works, Canadian Allis-Chalmers, Ltd., Drummond McCaul Co., R. D. Wood Co., Simplex Meter Co., and Builders' Iron Foundry.

BUILDINGS

Calgary, Alta.—The Federal estimates provide for $250,000 for the completion of the drill hall here.

Hamilton, Ont.—The Canadian Westinghouse Co. will build an office building to cost $150,000. Prack & Perrine, Toronto, are the architects.

Hamilton, Ont.—The Technical Committee of the Board of Education has practically decided not to proceed with the erection of the new technical school on Wentworth street until after the war

Toronto, Ont.—A building permit was granted by the city architect to the Harry Webb Co., to erect a two-storey brick bakery at the southwest corner of Kendall avenue and Davenport road, at a cost of $60,000.

Hamilton, Ont.—At a special meeting of the Board of Education, it was decided to proceed with the erection of a ten-room addition to the Adelaide Hoodless School, at a cost of $63,907. The lowest tenders in each case had been accepted .

Orillia, Ont.—A by-law to raise by debenture $18,000 for the completion of a new municipal building was carried on Feb. 12, by 98 majority. The vote was small. The original by-law carried a year ago was for $35,000. It is expected the new building will be opened early in March.

New Westminster, B.C.—In preparation for an early start on the construction of the N. P. freight warehouse on the waterfront, the contractor, H. W. Harrison, is having the various preliminaries arranged. Mr. Harrison has let a sub-contract for 19 steel rolling doors for the warehouse to T. J. Trapp & Co., Ltd. They will cost in the neighborhood of $4,000.

Winnipeg, Man.—Tenders for the completing of the new Parliament Buildings were opened on Feb. 12 by Thos. H. Johnson, Provincial Minister of Public Works. The lowest tender on the main contract was submitted by the George A. Fuller Co., the price being $1,171,823. Tenders were also sent in by the James Ballantyne Co., for the heating and ventilating, at $170,700; the Mundy, Rowl Co., for electric conduit and wiring at $101,036. The grand total for the new work is $2,230,902, which, in addition to the amount already expended of about $2,364,000, makes the total cost $4,594,902.

INCORPORATIONS

Superior Electrics, Ltd., has been incorporated at Ottawa with a capital of $100,000 to manufacture electrical appliances of all kinds at Pembroke, Ont. The incorporators are John H. Reeves, L. S. Mackie and James R. Lockhart all of Pembroke, Ont.

The Aspinwall Canadian Co., has been incorporated at Ottawa with a capital of $75,000 to manufacture machinery, motors and mechanical appliances of all kinds at Guelph, Ont. The incorporators are Lawrence Jacques, Allen E. Turner and Nicol Geffrey all of Guelph, Ont.

Paint Products Co. of Canada, Ltd., has been incorporated at Ottawa with a capital of $500,000 to extract and prepare minerals and deposits for the manufacture of paints, etc. The head office is at Montreal and the incorporators are J. B. D. Legare, Armand Mathiew and Robert T. Mullin all of Montreal.

Ford Tractor, Co. of Canada, Ltd., has ben incorporated at Ottawa with a capital of $10,000,000 to manufacture motor tractors, machinery and equipment in connection with same also to take over the patent rights within the Dominion of the Ford Tractor. The head office is at Toronto and the incorporators are H. G. Keen, John F. Boland and E. P. King all of Toronto.

TENDERS

Toronto, Ont.—Tenders, addressed to the chairman of the Toronto Electric Commissioners, will be received until March 28, for synchronous condensers. Specifications may be obtained at the office of the purchasing agent, 15 Wilton Avenue, Toronto.

Windsor, Ont.—Tenders will be received by the engineer R. W. Code, up till March 1, for supplying all labor, tools and materials necessary for the construction and completion of one cast iron intake and concrete well for the Eau Claire Waterworks Co., Tecumseh, Ont., according to plans and specifications prepared by R. W. Code, C. E. Windsor.

Winnipeg, Man—Tenders will be received up to March 15, by R. D. Waugh Chairman of Commissioners, Greater Winnipeg Water District, for the supply of approximately 12,500 feet of 48-in. and 1,300 feet of 60-in. cast iron pipes, together with specials and gate valves. Specifications on application to the offices of the District, 501 Tribune Building, Winnipeg.

Toronto, Ont.—Tenders will be received, addressed to the Chairman, Board of Control, City Hall, up to Feb. 27, for the construction of a drainage system (wrought iron pipe), for the Rosedale Bridge, Bloor Street Viaduct. Specifications and forms of tender may be obtained upon application at the Bloor Street Viaduct field office, 89 Castle Frank Road, Toronto.

Windsor, Ont.—Tenders will be received up to Feb. 28, 1917, for the construction of the superstruction of:—(a) One 70-foot clear span bridge. (b) One 80-foot clear span bridge. (c) Two 100-foot clear span bridges. Plans and specifications may be seen at the office of J. J. Newman, Davis Block, Windsor, Ont., or at the office of H. J. Rocheleau, Stoney Point, Ont.

Windsor, Ont.—Tenders will be received up to March 1 by R. W. Code, Board of Trade Building, Windsor, Ont., engineer, in connection with the erection of waterworks to cost $20,000, by the Eau Claire Waterworks Co., Tecumseh, Ont., for two centrifugal pumps and motors installed complete of 250 gallons per minute capacity. Specifications and all details at office of R. W. Code, engineer.

Hamilton, Ont.—Tenders will be received by the Board of Control up to March 5, for the supply of ordinary and special castings, iron pipe, hydrants, valves, extension boxes. Lead pipe—pig lead, rubber hose, rubber boots, road oil, lubricating oil, flux, fuel oil, coal oil, gasoline, brass work, including ordinary and special brass castings for water department, hardware, etc. Specifications may be obtained at the office of E. R. Gray, city engineer.

Winnipeg, Man.—Tenders, addressed to the Chairman, Board of Control, will be received up to February 26, for the supply f.o.b. Winnipeg, freight and duty paid, of from one to three gasoline or electric driven motor trucks or from two to five-ton weight, with two or four-wheel drive, body capacity not less than six cubic yards, and with or without crane attachment capable of lifting 500 lbs. Information for bidders may be obtained at the office of the Street Commissioner, corner James Avenue and King Street, Winnipeg.

PERSONAL

John H. Bunting, joint manager of Bruce Peebles & Co., Edinburgh, Scotland, has been appointed general manager of the company.

Harry McLaughlin, surveyor of customs at Montreal, has been appointed shipping master of that port in succession to R. S. White, resigned.

Charles J. Stark, of New York, has been appointed editor of the *Iron Trade Review*, and will shortly assume his new duties at Cleveland. Mr. Stark has been connected with the editorial staff of this journal for over a decade, having been associate editor both in Pittsburg and in New York City.

Capt. Reginald B. Bassett, member of the Lake Masters' Association, died at the residence of his parents, 24 Tyndall Avenue, Toronto, on February 17. He was born at Collingwood, Ont., 33 years ago. Previous to sailing the Mariska for the Bassett Steamship Co., he was master of the J. A. McKee, belonging to the Western Steamship Co.

Captain Robert A. Bartlett, Peary's navigator of the Roosevelt on the successful expedition to the North Pole in 1909, will go again into the Arctic Ocean in 1918, and is now preparing plans for a wooden ship, 135 feet long, to be built in one of the yards on the Pacific Coast. Bartlett will inspect the yards on the Pacific this spring and select a site for the building of his vessel.

TRADE GOSSIP

Goldie & McCulloch Co., Galt, Ont., have been awarded a contract for three 350 h.p. boilers for the Middlesex Mills Co., London, Ont.

Iroquois Falls, Ont.—The Abitibi Power & Paper Co. new sulphite mill will, it is understood, be operating by May. The new paper machines will double the company's output of news-print before the end of the year.

The Taylor Engineering Co., of Vancouver, B.C., are handling the Bolinder crude oil engine which is built in Stockholm, Sweden. Twenty-four engines of this type have already been sold to shipbuilding firms in British Columbia.

Heap & Partners, Ltd., Montreal, has been changed to Samuel Osborne & Co. The company has secured a factory on Seigneurs Street, Montreal, and has equipped it for producing high-speed tool steel. S. C. Burk is superintendent.

The General Machinery & Equipment Co., Vancouver, B.C., has opened offices in the Birks Building, that city. The firm will handle a general line of contractors' and mining equipment, also railway supplies. John MacKenzie is managing director of the company.

The Armstrong Whitworth Co., of Canada, Ltd., Montreal, have opened a branch at 27 King William street, Hamilton, Ont., where stock will be carried to take care of their Ontario trade. The Hamilton office will be under the management of F. T. Malone.

Ottawa, Ont.—The Government is sending overseas shortly six more portable sawmills for the preparation of lumber for use on the western front. Already a number of such mills have been sent abroad with forestry units, and have given satisfaction.

Canadian S. K. F. Co., has been organized under Dominion Charter for the manufacture and sale of S. K. F. self-aligning ball bearings in Canada. All correspondence should be directed to Toronto in which city headquarters have been established at 47 King street, West.

Drastic Embargo on Imports.—Andrew Bonar Law, Chancellor of the Exchequer, stated in the House of Commons that the British Government had decided upon very drastic restrictions on imports. The new measures, he added, would affect the Allies of Great Britain and the British Dominions.

Montreal, Que.—The Southern Canada Power Co., in extending its system throughout the Province of Quebec, has taken over the Brome Lake Electric Company, supplying the towns of Waterloo, Knowlton, Foster, etc. The company is now supplying light and power to 35 cities and towns in the province.

U.S. Navy Shell Orders.—The United States Navy Department has awarded a contract for 15,000 14-inch shells at \$500 each to the Midvale Steel Co., the Crucible Steel Co., and the Washington Steel and Ordnance Co., each company getting practically one-third of the award. These are the contracts which Hadfields Ltd., were not allowed to accept.

Newsprint Paper Reduced.—An official statement was issued at Ottawa last Saturday with regard to the fixing of a maximum price for Canadian newsprint, as sold to newspapers in the Dominion. The statement announces that the pulp and paper manufacturers, with whom the matter has been left, will determine their course on Wednesday.

The Export Association of Canada, Montreal, has directed its general manager, R. J. Younge, to proceed to South Africa as soon as possible to open up trade connections in that market for the members of the association. Mr. Younge will leave just as soon as he can gather together the necessary information from those firms who are interested—probably next month.

Russia Will Build Mercantile Fleet.—A despatch to Reuter's Telegram Co., London from Petrograd says the Russian Minister of Commerce has introduced in the Duma a bill under the terms of which the Government will devote 100,000,000 roubles toward the creation of a Russian mercantile fleet. The money is to be employed in advances to shipbuilders to encourage the construction of new shipyards and to provide equipment for them.

Enquiry for Track Material.—Albert Frost & Co., Sheffield, England, are open to purchase track materials as follows: 1,000 tons of flat bottom rails, 18 lbs. per yard section, punched for nails, and in 6 ft. and 9 ft. lengths; 50,000 gross cub. sq., bolts and nuts, 5-16 and 3/8 in.; 250 tons railway spikes 2½ in. and 3 in. by 5-16 in. and 3/8 in.; 250 tons wire nails, 2½ in. by 5-16 in., and 3 in. by 5-16 in. Delivered f.o.b. English port. Lists and full particulars to be mailed in advance.

Investigating Niagara Development.—It is stated that a corps of engineers is engaged upon an examination and inspection of all power company plants at Niagara Falls, Ont., with a view to determine for the Ontario Government if the water is being utilized with a proper degree of efficiency or economy. It is believed that this may have an important bearing upon the production of power upon the Canadian side, to meet Hydro and other demands.

The S. Morgan Smith Co., York, Pa., have closed a contract with the Saguenay Light & Power Co., Chicoutimi, Que., for two turbines, each of 2,500 h.p., to be direct connected to generators, and one turbine of 175 h.p. for an exciter unit. The turbines will work under a head of 53 feet. They are to be fitted with Lombard oil pressure governors. The present plant consists of one generator turbine and one exciter turbine of the same capacity as the new equipment ordered.

Russian Iron and Steel.—The production of pig-iron in Russia during 1915 was 4,062,100 tons, as compared with 4,769,300 tons in 1914. The output of semi-finished steel was 4,539,100 tons, as compared with 5,508,800 tons; and that of finished steel 3,590,500, as compared with 4,334,100 tons. Of the semi-finished and finished steel, 60 per cent. was produced in Central Asia, while the Ural region made 20 per cent. Of the pig-iron made in Russia in 1915, rather more than 70 per cent. was produced in Central Russia.

Market for Ships.—A representative of a large shipbuilding company now in New York, says France and Great Britain are in the market for all ships the shipbuilding companies can turn out. This is the first time in history that Europe has asked this country to supply ship tonnage. American shipbuilding companies are crowded with work, and few ships can be built for foreign countries. The same shipbuilder says this country will be kept busy turning out ships at least five years after the end of the European war.

Marine Association Elect Officers.—The annual meeting of the Dominion Marine Association was held last Thursday at the King Edward Hotel. A. E. Burke, the retiring president, presented the annual report of the association.

A. A. Wright, of the Montreal Transport Co., was elected president for the ensuing year, and will have J. T. Mathews, of Toronto, as his first vice-president, with A. E. Mathews, of the Mathews Steamship Co., acting as second vice-president. Francis King, of Kingston, was re-elected secretary.

B. C. Lead Production.—The lead production of Canada is almost wholly derived from British Columbia, the production of which is about 65,000,000 pounds a year. This metal is at present produced almost entirely from the mines of East and West Kootenay. The ores are smelted at Trail smelter, and the lead is refined there. On the coast and along the route of the G. T. P. are important deposits of lead ores which cannot be economically treated for want of smelting accommodation on the coast. The establishment of a lead smelter and refinery on the coast is, therefore, a necessity to the development of ore deposits tributary thereto.

Industrial Council Meets.—Sittings were held at Ottawa last week by the advisory council for scientific and industrial needs, appointed by the Government in November. Dr. A. J. MacCallum, presided over the sessions and members of the council in attendance included Dr. F. D. Adams, McGill president; W. C. Murray, University of Saskatchewan, Saskatoon; President A. S. MacKenzie, Dalhousie University, Halifax; Dr. R. F. Ruttan, McGill, Montreal, and Prof. J. C. McLennan, Toronto University. Organization work has been engaging the attention of the members of the council but steps are being taken to institute a number of inquiries which will be of benefit to the industrial development of the Dominion.

Electrolytic Refining of Copper.—The essential feature of electrolytic refining of copper is cheap hydro-electrical power, which is abundantly available in British Columbia, and smelting and refining plants to treat the ores now exported are required. The production is about 25,000,000 pounds per annum, and is capable of considerable increase. There is one refinery operating an electro-chemical process at Trail with a capacity of about 15,000,000 pounds spelter per annum. Another small refinery is being installed in the interior, Nelson. Nearly all the zinc ores are now produced in the interior, and the excess production over present refinery capacity, amounting to 10,000,000 pounds, has to be exported.

Coal Transports Heavy.—According to figures supplied by the Department of Customs at Ottawa there came into Canada in January, 1917, 30,440 tons of anthracite and 483,947 tons of bituminous more than in 1915, and yet there was no shortage in 1915. Conditions were somewhat similar in January, 1916, when 5,258 more tons of hard coal came in than this January. In January, 1917, 300,836 tons of anthracite, 217,339 tons of bituminous black and 814,380 tons bituminous lump coal were imported. In January, 1915, the 270,396 tons of hard coal that came into Canada was valued by the Customs authorities at $1,273,162, or about $4.71 a ton. In 1916, 295,578 tons were valued at $1,373,605, or about $4.65 a ton. The 300,836 tons that came in last month are valued at $1,572,882, or $5.23 a ton.

London, Ont.—The Canadian Cereal & Flour Mills Co. has disposed of its 400-barrel mill at London, to the Quaker Oats Co., of Peterborough, Ont. The Quaker Oats Co. has also purchased a 300-barrel mill at Neepawa.

Uses of Molybdenum. — The greater demand for molybdenum since the outbreak of the war on account of its use in hardening steel was dwelt upon by Mr. G. C. Mackenzie, B.Sc., of the Department of Mines, Ottawa, in a lecture given on Saturday night before the Royal Canadian Institute, Toronto. Australia and Norway were formerly the two greatest producers of the mineral, said Mr. Mackenzie, but the demands made upon Canada and her deposits of the metal were bidding fair to make the Dominion the largest producer. Mr. Mackenzie went on to describe the method of separating the mineral from the ore. Deposits had been found in British Columbia, Ontario and Quebec, and one company at Orillia, Ont., was making special advances in the manufacture of by-products from the mineral.

RAILWAYS—BRIDGES

St. John, N.B.—The St. John Street Railway Co. will sell out to the New Brunswick Investment Co., a holding company organized for the purpose of making the purchase and it in turn will make a transfer to the New Brunswick Power Co. The latter controls water powers at Magaguadavic and Lepreaux and it is their intention to operate by hydro electric power instead of generating electricity by steam as at present. Prospective purchasers also plan considerable extension of the lines and introduction of more modern methods in operation of the company.

CONTRACTS

Merritton, Ont.—The Robertson Cataract Electric Co., have been given the contract to install the fire alarm system at $718.78.

Montreal, Que.—Anglins, Ltd., has been awarded contract for a shipbuilding berth for the Canadian Vickers Co., Montreal.

Brantford, Ont.—The City Council have accepted the tender of the Watrous Engine Works for a boiler for the pumping station.

Port Arthur, Ont.—A provisional contract has been let by the Port Arthur Pulp & Paper Co., to the Wickes Boiler Co., Saginaw, Mich., for three 365 h.p. boilers.

Toronto, Ont.—The following contracts have been awarded by the York Township Council for the waterworks system. For 6-in. pipe National Iron Works, $10.40 per length; 12-in. pipe, Canadian Allis-Chalmers, at $26.75 per legth; 1,150 lengths 24-in. pipe National Iron Works, at $84,35 per length; automatic air valves, Drummond-McCall Co., at $16.50 each; special 24-in. cast iron pipe, National Iron Works, at total of $702.05; 6-in. and 12-in. special castings, National Iron Works, $220.85; valves, the Chapman Valve Co., at prices of $410 and $105 according to specifications. These prices were, according to the township engineer, F. Barber, all well within his previous estimates.

MARINE

Vancouver, B.C.—City Engineer Fellowes has prepared a report on harbor development in which it is suggested than an area of False Creek be retained for factory sites.

Victoria, B.C.—The keel for the fourth auxiliary schooner was laid at the Cameron Genoa Mill Shipbuilders, Ltd., shipyard, on Feb. 6, on the ways occupied by the schooner Margaret Haney, which was launched recently.

Esquimalt, B.C.—Messrs. Yarrows, Ltd., have secured the contract for overhauling and repairing the American four-masted barkentine Puako, which arrived recently from Durban, South Africa, after a passage of 103 days.

Port Arthur, Ont.—Ice conditions at this end of Lake Superior favor an early opening of navigation. Open water commences at Thunder Cape, 18 miles out. The weather has been cold, but high winds have kept the ice broken up

Esquimault, B.C. — The municipal council has decided to memorialize the Provincial Government on the Esquimault drydock question, recommending that pressure be brought to bear upon the Federal authorities to have the undertaking carried out without further delay.

Midland, Ont.—A movement has been started to have a dry dock established here. In the furtherance of the scheme a deputation has visited Ottawa and asked for assistance in the work of dredging in connection with the proposed dry dock and shipyard.

Chatham, Ont.—Engineers Porter and Griesback, of the Department of Public Works, Windsor, Ont., have commenced the work of making soundings in the River Thames from Chatham to the lighthouse. The report is being prepared in connection with the proposal to dredge a fourteen-foot channel from Chatham to Lake St. Clair.

North Vancouver, B.C.—The Wallace Shipyards have been awarded the contract for effecting the repairs to the G. T. P. steamer Prince John necessitated through the vessel's recent stranding in Wrangell Narrows. About 15 plates will have to be replaced and it is reported that slight injury to her engines and frames was sustained.

Cunard Line Places Orders in U. S.—Contracts for ships to cost over $13,000,000 have have been awarded the Harlan & Hollingsworth Corporation, of Wilmington, Delaware, by the Cunard Line and the United Fruit Co. It is the first time either concern has ever placed contracts with an American shipyard

The vessels for the Cunard Line are to be freighters of 15,000 tons capacity.

CATALOGUES

Power Hammers.—Bulletin describing the product of Beaudry & Co. Inc., Boston, Mass. The principal constructional features of the "Champion" and "Peerless" hammers are described at length and the claims in their favor set forth in detail. Among the illustrations are included views of the mechanisms, while tables give the principal dimensions and the other data for each of the various sizes of hammer.

Monometer Mfg. Co., Birmingham, England, have issued two bulletins dealing respectively with the "Monometer" metal melting furnace and automatic heat control. The former describes and illustrates the furnace, and also contains a number of testimonials from satisfied users in Great Britain and the United States. In the other bulletin, the "Monometer" self-acting heat regulator is described, and the work for which it is adapted, dealt with. A leaflet is included, giving the standard prices for the above in various sizes, and also for low pressure gas burners.

The Hydraulic Press Mfg. Co., Mount Gilead, Ohio.—Export Catalog No. 70, "Hydraulic Presses and Pumps". Size 8 in. x 10 in., 84 pages, describes and illustrates their line of hydraulic machinery adapted to foreign distribution. The first 7 pages are devoted to general data; pages 8 to 35, inclusive, to metal working presses; 36 to 40, inclusive, to veneer presses; 41 to 44 to baling presses; 47 to 48 abrasive wheel presses; 50 to 56, inclusive, leather presses, 57 to 67, inclusive, butchers and packers presses; 68, 69 and 70 to oil presses; 71 cider, wine & Grape juice presses; 72 and 73 hot plate presses; 76 hydraulic pumps. A copy will be sent to interested concerns.

BOOK REVIEWS

Mechanical World Pocket Diary and Year Book for 1917, 453 pages, 6 in. x 4 in. Norman Remington & Co., Baltimore, Md. Price 40 cents post free. The 30th annual issue of this year book, published by Emmot & Co., Manchester, contains several new features, while the book generally has been thoroughly revised. The section on steam and the steam engine has been rewritten. New tables have been introduced, giving dimensions of piston rings, governors, etc., while notes on lubrication and anti-friction bearings are now included. A new section on the heat treatment of steel has been introduced, including notes on annealing, hardening, tempering, etc. Other new matter includes tables, giving dimensions of flanged couplings and calculation of springs. Much recent information is also given regarding design of prime movers, boilers, power transmission, machine shop practice and materials. A 57-page diary and memoranda is a useful feature of this publication.

FOR SALE

FOR SALE—ENGINE LATHE 30" SWING, 8 ft. bed. Putnam make, good strong tool, cheap. Box 269, Canadian Machinery. (c8m)

FOR SALE — LOT OF WOODWORKING machinery — shafting, pulleys, hangers, belting, etc. Cheap. Box 270, Canadian Machinery. (c8m)

FOR SALE—TEN TONS ⅝" HIGH DUTY galvanized steel guy wire, made up of 7 strands of 3-16" wire—low price. Winnipeg Machinery Exchange, Sutherland St., Winnipeg, Man. (c8m)

GAP LATHE, 28 x 42 x 16 FT. BED, FOR sale, cheap; also emery wheel stand, power back saw. Guarantee Motor Co., Hamilton, Ont. (tf)

FOR SALE — 1 NEW SHORE SCLEROscope, complete with all regular equipment. Pease Foundry Company, Limited, Brampton, Ont. Jct. 4341. c6m

SHRAPNEL SOCKET AND ADAPTER machinery, turret lathes, boring machines, cutting-off machines and thread millers tooled for operation. Globe Electric Machine Co., Hamilton. (tf)

FOR SALE—ONE 450 H.P. THOMPSON & Williams condensing engine. Will sell cheap. Engine is in first-class repair and will give every satisfaction. Apply J. A. Marven, Limited, Moncton, N.B. tefm

1—2-SPINDLE SHAPER, WOOD TOP, JOHN Ballantyne, Preston, make, used two months. 1 Dynamo, 45 lights, Toronto and Hamilton Electric Co. make. Used five months. Good as new. Box 195, Jordon, Ont. (R.T.F.)

25 CYCLE MOTORS IN STOCK TORONTO. Sizes in horse-power tens, fifteens, twenties, thirties, forties, fifties, seventy-five and one hundred fifty, standard voltage, slow speed. Boyd-McBurney, 220 King St. West. Main, 2330. c7m

ONE LATHE 16" x 4½' back geared. Built by P. P. Silk Machine & Tool Co., Cincinnati, Ohio. One lathe 18" x 3', back geared. Built by the Bradford Mill Co., Cincinnati, Ohio. Four Murchey Collapsible Dies. Capacity 1½" to 2½". Box 272, Canadian Machinery. ctmf

1 ONLY — 10" WESTINGHOUSE LOCOMOTIVE air compressor, first-class condition, all complete, ready for installation. 1 only, 6 x 6 Imperial type Canadian Ingersoll-Rand Company air compressor, in good condition, complete, ready for installation. H. Mueller Mfg. Co., Ltd., Sarnia, Ont. c8m

FOR SALE—2 KENNEDY CUTTING-OFF machines, for cutting off both ends of 4.5 H.E. forgings; in good condition; price $750 each. 1 18-pdr. Holden-Morgan thread miller for threading base end of high explosive shells; price $300. 1 18-pdr. H.E. marking machine; price $50. Apply to Alton Foundry Co., Ltd., Alton, Ontario. c13m

WANTED

SHOP IN WINDSOR, ONT., EQUIPPED partially or wholly for special machine, tool and repair work. Send full details. F. G. Hubbard, Box 852, Bridgeport, Conn. c9m

WANTED — MOTORS 10 TO 50 HORSEpower, 25 cycle, 550 volts, alternating current. Quote price and delivery. Canadian Fairbanks-Morse Co., 1379 Bloor Street, Toronto. c11m

SPECIAL MACHINERY

FUSE EQUIPMENT — SPECIAL MACHINery for manufacturing fuses, including rethreading machines for base plugs, with tools. "Harris," Box 1008, Bridgeport, Conn. c9m

MANUFACTURERS — WE CAN UNDERtake work to any specification—munition production equipment or otherwise. Write W. H. Sumbling Machinery Co., 7 St. Mary St., Toronto.

Machine Shop

FOR SALE

Toronto, going concern, Universal milling machine and grinder, 4 machine lathes, 2 Fox lathes, shaper, drills, etc. Modern tools, A1 condition. Good lease; splendid central location.

INDEX TO ADVERTISERS

Machining the 4.5 ins. Mark VII Howitzer Shell

By H. G. Evans

In our January 11, 1917 issue, there appeared an illustrated descriptive article covering the "Machining of the 4.5 ins., Mark VII, Howitzer Shell," the data for which had its origination in a plant close to the extreme Western limit of our far-flung Dominion. The reference then made to the width of scope of munitions manufacture within our borders receives the necessary substantiation in the case of the present article, the constituent detail of which typifies production of the same type shell in a plant whose location is well nigh to our extreme Eastern boundary, or, in other words, is operative on our Atlantic seaboard.

THE new 4.5 in. Mark VII. howitzer shell being such a radical departure from the old Mark V., presents many little points of difference in the method of manufacture which add to the difficulties of successful production. Just at this period, when so many firms are changing over to this type, it may be interesting to study some of the methods employed relative alike to quality and quantity output. The plant from which the following data was procured has been working on this class of shell for several months, and an output of about 500 shells per day is now being maintained. Two years ago, when the shell-making industry was in an incipient state, and the outlook appeared to be one of short but abnormal activity, this firm, when purchasing machinery to augment their existing equipment, did so with a view to utilizing it more for future trade than for conditions as they appeared at that time. This firm, however, in common with many others with a similar lack of forethought, are now looking with a certain degree of envy upon the numerous special machines that have been placed on the market for the more economical production of all classes of shells. Nevertheless, much credit is due to those manufacturers who have successfully solved the problem by the use of special fixtures alone, adapting these to available machines with very satisfactory results. Next to special equipment, the one factor that tends to higher efficiency is the machine tool layout, which should be so designed as to minimize the handling of the shells as they progress through the shop. While this shop may not be ideal, a glance at the plan, Fig. 1, will give some conception of the continuous movement of the shells from the rough forging to the finished product.

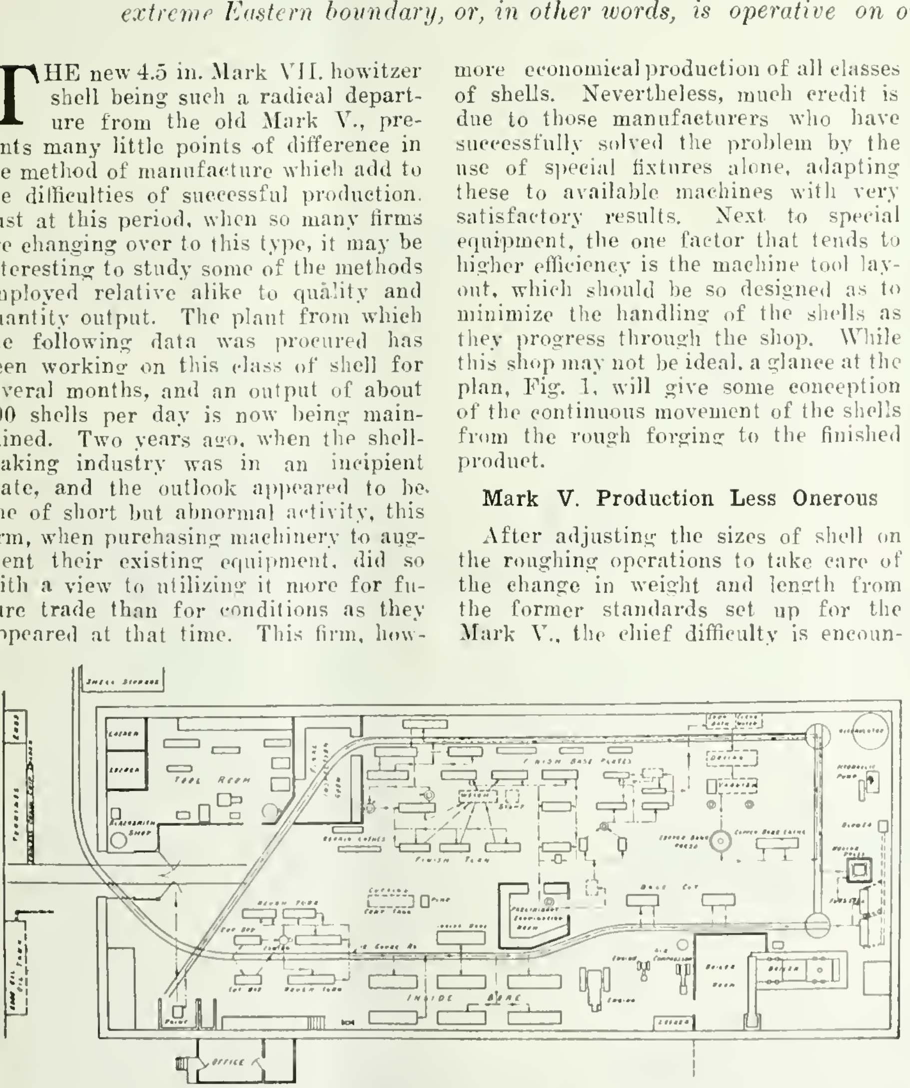

FIG. 1. MACHINE LAYOUT OF 4.5 INS. SHELL SHOP.

Mark V. Production Less Onerous

After adjusting the sizes of shell on the roughing operations to take care of the change in weight and length from the former standards set up for the Mark V., the chief difficulty is encountered in securing sufficient stock on the inside of the shell nose to form the shoulder below the undercut. It is the practice of some shell-makers to upset the shell under the press, but this is often a risky and unsatisfactory method. Owing to the greater depth of nose metal required on this type, it is necessary to have the outside diameter at the mouth sufficiently large for the purpose; and

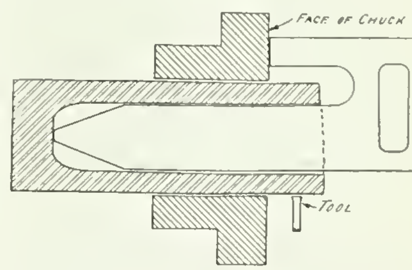

FIG. 2. APPLICATION OF CUTTING-OFF GAUGE.

due to eccentricity of many of the forgings, much difficulty is often experienced in obtaining good results when nosing. For satisfactory work, the diameter for about 2⅜ inches back from the open end should be at least 4 13-16 inches, and slightly larger would prove even more effective; however, owing to the varying characteristics of the forgings, many shells will not clean up to a greater diameter. It has been found that a proper nosing process is a very essential factor, and considerable care is exercised in all preliminary operations to insure accurate work on the press operation. Every facility is provided to have the ends cut off square with the axis of the shell.

The plant is operating 22 hours per day on two shifts; the latter alternating every week with satisfaction to the firm and appreciation by the workmen. The routine of the work is divided into three departments—roughing, nosing and finishing, each department having its own night and day foreman. The washing, varnishing, etc., are under the supervision of the press foreman. The assistant superintendent has full charge of the mobilization of shells through the shop, seeing that heat numbers are correctly transferred, keeping the machines supplied with shells, and otherwise exercising every vigilance in expediting their progress through the shop. The watchword of this plant is "Rigid Inspection," and its success, in a great measure, is due to the strict observance of specifications and careful gauging methods.

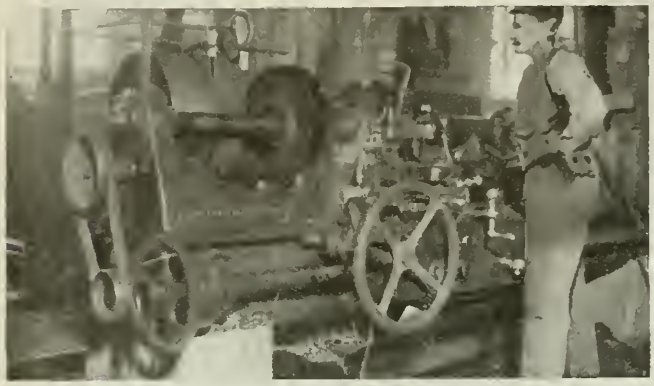

FIG. 3. ROUGH TURNING ON "GOULD & EBERHARDT" MACHINE.

Fig. 1 is a layout of the shop and general arrangement of machines, from which it will be noted that shells follow a straight course up the right-hand side from A to B, thence from B to C. From C they are transported on trolley cars to D, whence they are started along the finishing side of shop to the preliminary inspection room E. From E to F they pass through all the final finishing operations, such as plugging, base facing, varnishing, banding and band turning. They are then placed in boxes and hauled to the final Government inspection room G, and from there to painting department H, where they are prepared for shipment and loaded in cars at I, being practically the point from which they started.

Cutting-off Open End and Centering Base

Two Davis cutting-off machines are used for cutting off the open end, the length measured from the inside being 12 1-16 inches. Fig. 2 illustrates the method of gauging. Care is exercised in cutting to exact length given, which is 3-16 inch shorter than the finished bore of shell, leaving that amount for the spade tools to remove. This is to keep the length of the large diameter of 4 13/16 inches constant ,and permit of bottom of shell being cleaned up without cutting shell back, and thus shortening the enlarged nose.

After the base is centered, which is performed on a 20-inch Barnes drill, fitted with expanding arbor and suitable jig, the heat numbers are transferred to the base by means of an ordinary cold chisel, this method proving as satisfactory as the use of a steel stamp. The shells are next examined for concentricity, and should the variation of wall thickness be such as to prevent outside cleaning up to 4 9-16 in. diameter, they are chucked in a rigid Conradson lathe, where the eccentricity is partly adjusted by boring with a single point tool.

The rough turning operation is accomplished on several old engine lathes; one of these, a Gould & Eberhardt, shown in Fig. 3, was headed off on its way to the scrap pile, rebuilt and pressed into service. The headstock was designed to suit the new requirements, pulleys being placed on the back gear shaft, a 5-inch double leather belt providing sufficient power to drive through the heaviest cuts. Increased elasticity has been given to the feeding mechanism by substituting a 1½-inch belt for the gears previously used. The use of the feed belt minimizes the breakage of tools and gears when unskilled workers carelessly allow the cut to run to a shoulder on the work. The usual hand feed was discarded and replaced by a large wheel with pinion meshing directly with the feed rack. These machines have an average output of about 10 shells per hour.

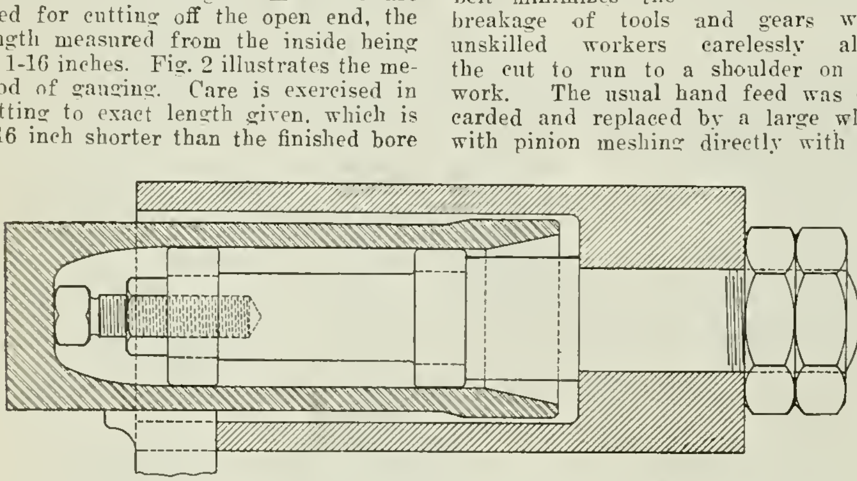

FIG. 4. SPECIAL CHUCKING DEVICE FOR "HALL" CUTTING-OFF MACHINE.

The sequence of operations on the bore are similar to those on other shells; that is, rough bore, rough base, finish bore, finish base, cut to length, and chamfer. The finished bore is 3.38 inches, with a tolerance either way of .003 inch; the chamfer has a depth of 1¾ inches, and a large diameter of 4⅛ inches. Chamfering the outer edge was tried, but the present method has given better satisfaction, as the shape after nosing conforms more to desired requirements. The length from the inner base to the open end is 12¼ inches plus or minus 1/64 inch.

Contrary to general practice, this firm does not remove any stock from the outside base until after boring. This not only eliminates previous base facing, but permits inside base being further machined, should defects appear, without materially affecting the thickness of metal. When doing this operation, it has been found advisable to fit the machines with a special arbor to avoid any possibility of sag when gripping the shell. This arbor, which is secured to a sleeve held in the body of the chuck, is provided with an adjustable stop that gauges the depth to which the shell is placed in the chuck. It is essential to have the base square with the axis of the shell, as it insures its standing perfectly upright in the nosing press. The thickness of metal at the base after facing should be 1 7/32 inches, with an over-all length of 13 15/32 inches.

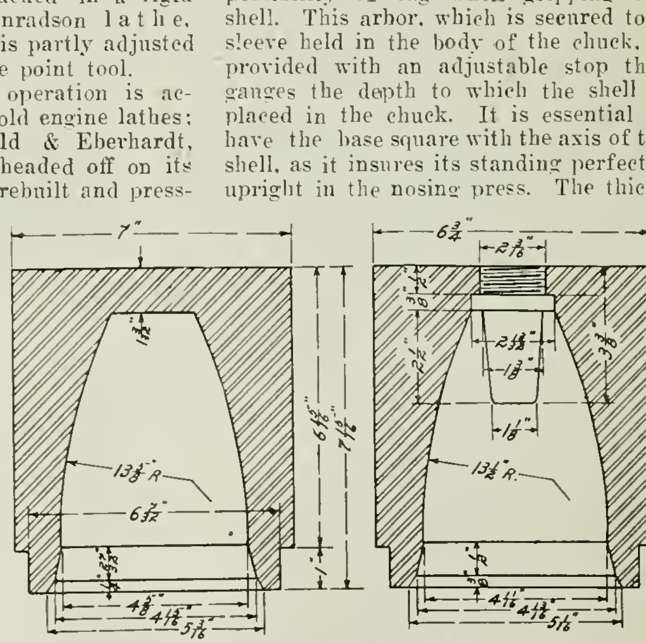

FIG. 5. NOSING DIES.

The Nosing Operation

The link that unites the roughing and finishing departments, that of closing in the nose, is probably the most important factor in the manufacture of this shell, as the success of subsequent machining depends largely upon the accuracy of the nosing process, which is more difficult of attainment on the Mark VII. than on the Mark V. Two five-hole oil-fired Mechanical Engineering Co. furnaces, fed by a Trehearn rotary pump, are installed Oil is delivered at a pressure of 25 lbs. and sprayed through nozzles into the fire chamber by means of high pressure air at 80 to 100 lbs. per square inch. Air for combustion is supplied at a pressure of 4 ounces. The shells are heated to almost white heat as far down as the bevel on the outside, and to insure an even distribution of heat the shells are turned at intervals, this precaution being

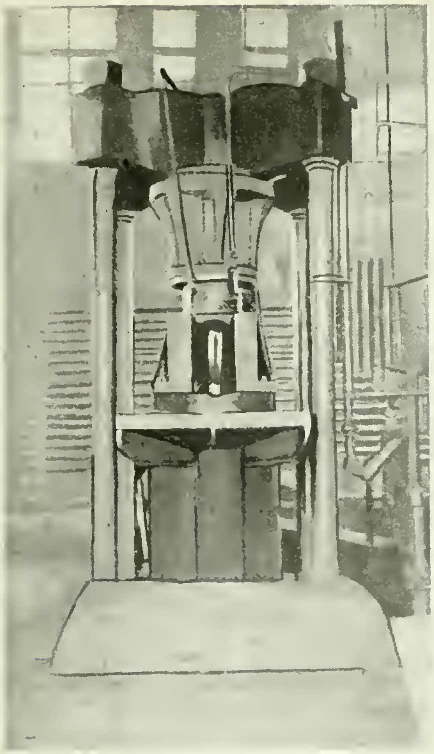

FIG. 6. NOSING OPERATION.

necessary, as unevenly heated shells are often the source of defective nosing. The alignment of the press should be periodically examined, as highly accurate work is only possible under the best working conditions.

The standard nosing is shown to the left of Fig. 5, but where the shells will not clean up to 4 13/16 inches diameter, it is necessary to upset in such a way that metal will be forced down to allow of sufficient thickness below the recess.

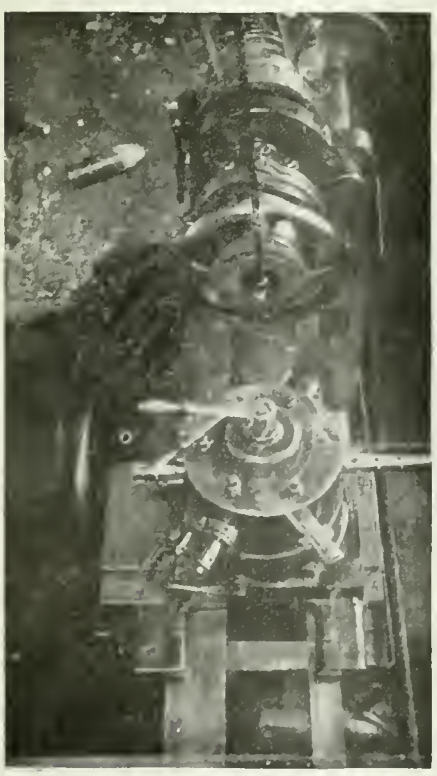

FIG. 7. AEROPLANE VIEW OF NOSE OPERATIONS

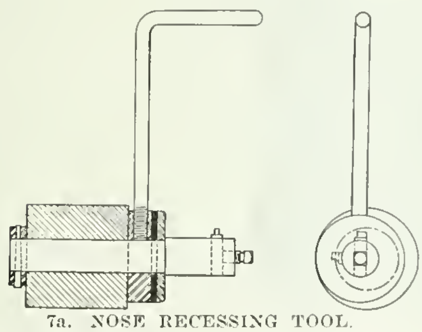
The die for this purpose is shown to the right. When using this die, shells are heated and nosed part way, and after a time are reheated about three inches down to a good white heat, and then forced right up to the top of the die and around the pin, which upsets shell slightly and forces metal down where required below the undercut. Fair success has been achieved by this method, but shells are very liable to bulge below the die unless carefully handled; besides, it is a slow and expensive method, doubling as it does the time and cost of nosing. After nosing, shells are placed in sheet iron boxes filled with air-slacked lime to anneal. Each box holds about 75 shells, and press foreman selects five shells from each box and has them finished as quickly as they can be cooled, to keep check on nosing operations.



7a. NOSE RECESSING TOOL.

Fig. 6 is a view of the press, and attention is drawn to telescoping die-holder and guide.

Nose Machining

An aeroplane view of nose machining is shown in Fig. 7, the sequence of operations being: rough bore, bore, counterbore and face, ream two diameters and bevel face, undercut, and tap. The recessing tool is shown in Fig 7A, this being a small bar operating in a hole which is eccentric to the bush held in the turret. Before the shells are removed from the lathe, they are inspected for thread diameter, perfection of thread and depth of undercut. By using a pair of inside calipers from the thread diameter to the opposite edge of the nose profile, the inspector can tell whether there is sufficient metal to clean up, and, if not, the nose is cut back another 1/16 inch. This necessitates a similar amount being removed from the back of the recess to maintain the proper depth.

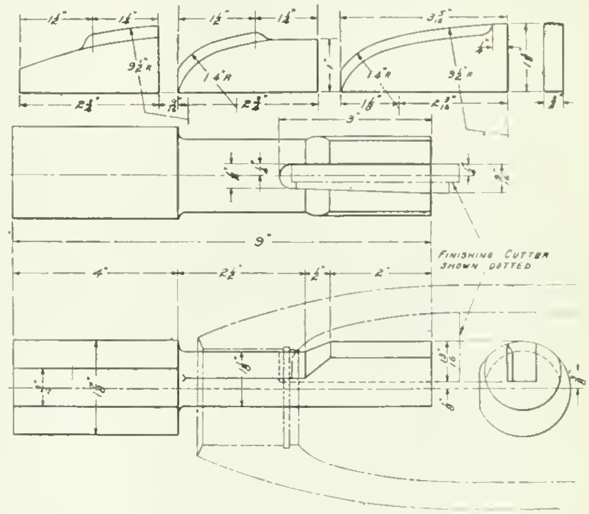


FIG. 8. TOOLS AND BAR FOR INSIDE NOSE PROFILE

Owing to the increased difficulties of nose operations and the greater degree of accuracy required, cross feeds were eliminated on the thread nosing operation, and the inside nose profile was finished on a separate machine. As the portion to be machined is often very uneven, three tools, shown in Fig. 8, are used, two roughing at different points and the third finishing the complete contour. Turret machines are used, each having a capacity of about 23 shells per hour. Hand sizing is necessary. The container seat hole is reamed by using reamers made from discarded taps.

Finish Turning

Three Cincinnati pulley lathes are provided for the finish-turning operation. These machines are of standard pattern, fitted with two carriages. Rex AA high-speed steel is used, feed being 21 turns to the inch; an average production of 12 per hour is maintained. A special bevel horseshoe gauge is used to gauge the nose of the shell before removing from

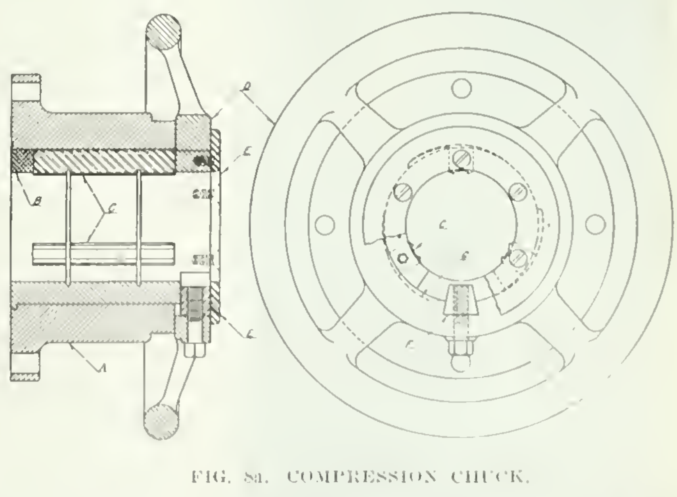

FIG. 8a. COMPRESSION CHUCK.

the lathe. In addition to the routine examinations at each operation, all shells are given a general inspection after the finish turn, following which they are weighed and marked for cutting to proper weight. From closely figured calculations, a chart has been devised showing the exact amount (in 64ths) to be removed from the base to bring the shell to the desired weight of 27 lbs. 3 ozs. As a guide to the machine operator, the weigher places a pop mark on the shell for cut-off position, and also one .72-inch nearer the nose to indicate the lower edge of the copper band groove. After the heat numbers are transferred and recorded, the groove for the band is cut in. One Reed and one Bertram machine are employed on this operation. Both these lathes are fitted with a special four-tool attachment, as shown in Fig. 9. The first tool is for roughing out to width, the second roughs out for the ribs, the fourth is for waving, and the third for undercutting. This arrangement is necessary owing to the fact that the tool for waving must be placed farthest from the generating cam, which is secured to the chuck or face-plate of the lathe.

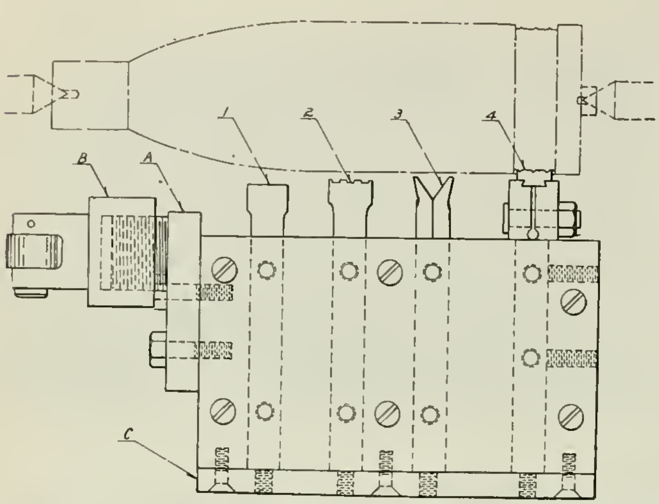

FIG. 9. TOOL ARRANGEMENT FOR GROOVE AND WAVE.

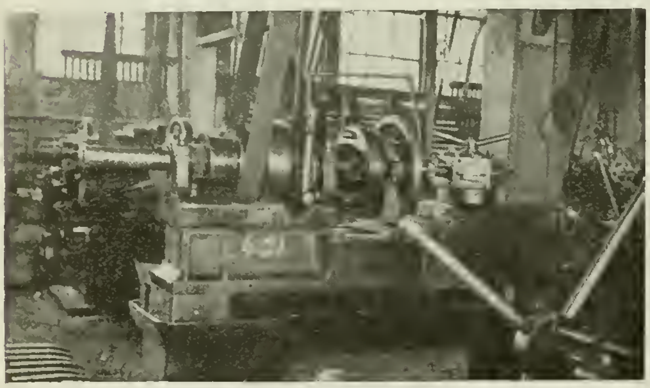

FIG. 10. BORING BASE ON "GARVIN" TURRET.

Fig. 10 shows one of the base recessing machines (Garvin) in operation, the chamber being completed in one machine. The depth is gauged from the edge of the rifling band groove, and it is important that the surface be perfectly flat when tested with a scale.

Cutting Nose Slots

After gauging and removing burrs, three slots are cut in the nose. A special fixture has been designed for this purpose and is shown in Figs. 11 and 12. The entire arrangement is supported upon a concrete base, the piece A that holds the inclined fixture being secured to the upper portion of a heavy cross slide. The chuck B is made in two parts, the section C swinging on a large pin with clamp bolts opposite. When the shell is placed in the chuck, it rests upon a short spring that forces it against the height gauge D. Plate E retains the base of the shell on its seat, but leaves it free to revolve to its several positions, these points being located by the locking bolt F operated by the handle G. The chuck is turned to its various positions by means of the hand wheel H. To prevent the cuttings from falling into the turret, a thin plate I is secured to the chuck. The fixture, with the shell, is moved beneath the cutter J by operating the cross slide handle L.

FIG. 11. NOSE SLOTTING MACHINE.

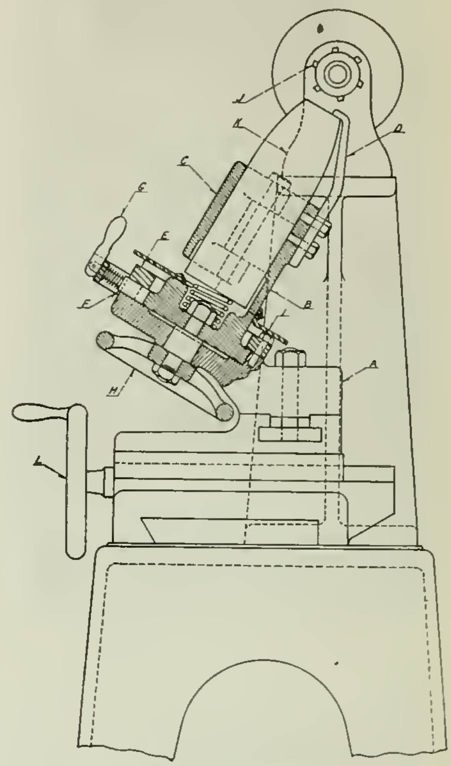

FIG. 12. SECTIONAL ELEVATION OF NOSE SLOTTER.

The special cutter designed for use on the nose slotter is shown in Fig. 13, and, while quite simple, is very efficient. It consists of an arbor A carrying the supporting sleeve B, upon which the tools bottom, these latter being held in the slotted collar C. The two nuts D provide means of adjusting cutter to the centre line of fixture. This slotting arrangement is capable of producing three shells per minute.

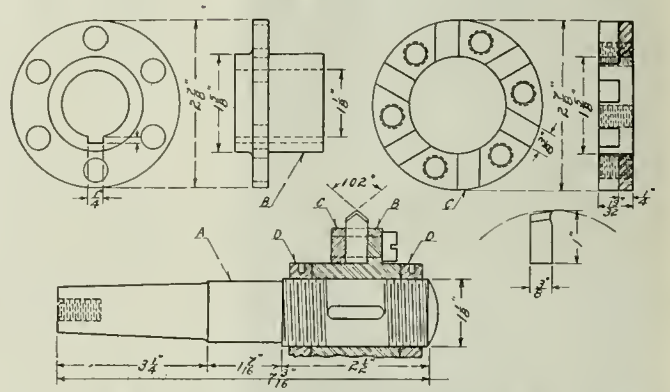

FIG. 13. MILLING CUTTER FOR NOSE SLOTTING MACHINE.

Following the preliminary Government inspection, the base plates are put in. While a good fit is required, no forcing or hammering is permitted for fear of the plate not seating on the base of shell. The method adopted for testing plates after riveting is by means of a bent pin placed on the base and tapping same with a light hammer, when a loose plate is easily detected. After the square is twisted off and the base faced, the shells are tested for dimensions and weight. The weight at this point, minus the copper band, which is reckoned at 11½ ounces, should be between 26 lbs. 12½ ozs. and 26 lbs. 6½ ozs., but to maintain a safe factor the shop inspectors endeavor to keep the weight between 26 lbs. 12 oz. and 26 lbs. 8 oz. If shells are under this low limit, a tag is attached to the groove to indicate that shell is to be fitted with a hot band. The source of error lies in the fact that no means of checking is available, as miscalculation when marking amount to be removed is not discovered until the shells are practically completed.

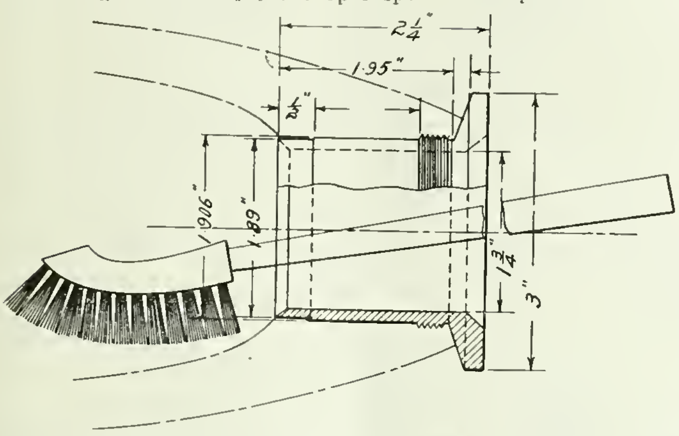

FIG. 14. VARNISH THIMBLE AND BRUSH.

Washing and Varnishing

Washing is performed by a jet of steam entering the nose when shells are submerged in a solution of sal soda. Varnish is applied by means of a brush through the nose of shell, the threads being protected by a brass ferrule, shown in Fig. 14. After this operation the shells are again hand tapped to remove surplus varnish.

FIG. 15. PAINTING MACHINE ANND DRYING RACKS.

Banding and Painting

Copper band operations are similar to those on other shells; the press having been supplied by the International Engineering Works, Amherst, N.S., and the turning lathe by Jenckes, Sherbrooke, Que. A record production on the lathe is that of 925 shells in 11 hours. When shells pass the final inspection they are painted in the "machine" shown in Fig. 15. This device is not patented, but is giving good satisfaction.

NOTES ON EXPORT PRATICE

By Commerce

TO shippers who are only occasionally concerned with the export of goods, the fact that a ton is not always a ton is somewhat confusing. A ship of a definite net register tonnage may be chartered, a cargo of a certain gross weight in tons shipped on her, or freight paid at the rate of $30 per ton, yet in every one of the three cases the ton referred to is quite a different thing. Consider first the "freight" ton. In the earlier days of merchant shipping this really had reference to a ton of 2240 lbs., the ton being derived from the old English beer measure of a ton, same being 209 gals., or about 2,200 lbs. Owing to the fact that some materials are very much lighter than others, it was found necessary to charge freight on the cubic capacity of the goods with their cases, and, at the present time, the "ton" referred to in freight quotations means nothing more or less than forty cubic ft. The weight basis still remains for heavy or bulk cargoes, but, for all ordinary freight, it is necessary to measure up the outside dimensions of the boxes or crates, estimate the space they will occupy in the hold and to divide the result by forty.

Register Tonnages

A ship has two register tonnages which are attached to her name in Lloyd's Register, these being "Gross" and "Nett." Both are measured in units of 100 cubic feet, or just 2½ times the freight unit. Gross tonnage is measured as the whole of the space below decks, plus the capacity of deck cabins, chart houses, and other covered structures. Nett tonnage is the difference remaining after deducting the quarters for the officers and crew, navigation and engine space, and bunkers. In other words, nett tonnage is the maximum hold capacity. It varies from 50 to 70 per cent. of the gross tonnage in an ocean going cargo steamer, and, as the cost of a ship is directly related to her gross tonnage whilst her earning capacity is a function of the nett tonnage, it is desirable to keep this percentage as high as possible.

In the case of passenger liners, the ratio of nett to gross is very small, whilst, in one of our typical grain or ore freighters for Lakes service, the nett tonnage will be considerably more than 70 per cent. of the gross. Nett tonnage is the basis of all marine statistics, port and harbour dues, and is the chief factor in the chartering of a vessel for cargo. It will be seen that to ship a 10,000 ton cargo a 4,000 ton freighter will give the required capacity. An exception to this occurs where the cargo weighs more than 2240 lbs. per 40 cubic feet, in which case, perhaps, not more than 25 per cent. in excess of the registered tonnage could be carried. With heavy cargoes, the maximum would depend upon the season, as it would take a greater displacement to sink a vessel to her marks in summer than in winter particularly on the North Atlantic.

Cable Codes

In any office transacting a considerable amount of export business, a great deal of time and money can be saved by a really intelligent use of the cable codes. In addition to the use of the Western Union and other standard codes for the abbreviation of telegraphic messages, it is always desirable for a firm to have a private cipher for cabling their confidential agents and correspondents at foreign points. Such a code will have the great advantage of secrecy: that is it cannot be decoded without the use of the private key. It will also be economical because it can be devised on a five letter system thus enabling any two words to be connected and transmitted as a standard ten letter word. Lastly, the interpretation will have particular reference to the firms own special products, classes of machinery, etc., which a commercial code cannot have. Let us devise such an arbitrary code as the above-mentioned, remembering that three rules must be followed, viz.

(a)—Every word used must be pronounceable (this is a stipulation of the Cable Company to assist their operators in securing accuracy).

(b)—Every word must consist of five letters, and, (c), each word must differ from every other by at least two letters. This last precaution ensures that the multilation of a word in transit will not give a false meaning to the message. For instance, if the word HAMID stands for 1000 and HABID for 2000 an error of transmission changing the M into a B might lead to the shipping of twice as many goods as were ordered.

Another illustration actually taken from the private code of a firm of electric cable makers is in the word LEAPED, signifying "hold order for instructions", and LEANED meaning "hurry forward goods on order." It is easy to see what trouble might result from a mix-up in transmission in this case. If however, every word is two letters different it is in the last degree unlikely that both would be so transposed as to give a false meaning, and, in nearly every case, an error would lead to an unintelligible message which the receivers would promptly have repeated.

Let us take as the root for our code the letter K; this can be followed by any of the five vowels, KA, KE, KI, KO, KU. Now, eliminating the inconvenient letter Q, there are twenty consonants which combined with the above will yield 100 different three letter words; viz. KAB, KAC, KAD, KAF, etc. Lastly comes another vowel and consonant, both of which must change with every word; viz. KABAC, KABED, KABIF, KABOG, KABUH, next, KABJA, KABKE, KABLI, KABMO, KABNU and then KACAP, KACER, etc.

The above illustrates sufficiently the method to be adopted in making up any arbitrary code which shall satisfy all the rules. It may be asked "why not choose ordinary five-letter dictionary words?" The objections are that considerable search would have to be made to ascertain that the words were not already in use in a standard code, and further, with a large list of words it would be a most laborious process to go through them in order to see that they fulfilled the "two letter change" rule. With the devised code above described, this automatically takes care of itself and the words can be made up just as fast as one can write them down.

In attaching meanings to the words, it is useful to let the three letter root denote a class of product and the suffix stand for the size or type. For instance, KAB-may be taken to mean "engine lathe," and the suffix-AC would be 10 ft. bed, or ED 12 ft. bed. KAC-might signify a riveting gun, AP being ½ ins. size, ER ⅝ ins. etc. Such a code as this would dwell in the memory and might find a certain use in private correspondence, stock lists and card indexes, thus saving much time and space.

In telegraphing such a code as this two words are always connected regardless of meaning, thus, KEDOBKABMO becomes KEDOB, KABMO, for decoding.

Standard Code Modification

Economy and secrecy are also obtained in cabling by modifying one of the standard codes according to a prearranged plan. This involves using the numbers which are attached to all the words in the code book. Looking through the Western Union, Liebers, or A B C 44th, or 5th. edition, it will be seen that a small proportion of the words are numbered from 100,000 up. This system will only apply to the first 99,000 words so those eliminated should be carefully noted; in any event the method covers the most useful part of the code book. By the use of the following table it will be seen every number from 0 to 99,000 can be represented by a pronounceable word:

	B	C	D	F	G	H	J	K	L	M	N	P	R	S	T	V	W	X	Y	Z
A	00	05	10	15	20	25	30	35	40	45	50	55	60	65	70	75	80	85	90	95
E	01	06	11	16	21	26	31	36	41	46	51	56	61	66	71	76	81	86	91	96
I	02	07	12	17	22	27	32	37	42	47	52	57	62	67	72	77	82	87	92	97
O	03	08	13	18	23	28	33	38	43	48	53	58	63	68	73	78	83	88	93	98
U	04	09	14	19	24	29	34	39	44	49	54	59	64	69	74	79	84	89	94	99

In above table, each number is represented by a vowel and a consonant, in other words by a pronounceable syllable; for instance 36 is KE (or EK). 53 is NO (or ON). To use the table let us take an actual message from the Western Union Code.

34628—Goods were improperly packed.

44162—Will not hold ourselves liable.

Putting these two numbers together in this way, 34-62-84-41-62, and substituting the proper letters from the table, we obtain JURIWULERI, which in one word carries the same message as the two words in the code. The receiver of such a message will just substitute the figures for the letters, divide the ten integer number into two of five integers each, and look up the meaning in the Code Book. It will be seen that, to represent such a number as 83, the symbol 00083 must be used so as to leave no blank spaces.

ELECTRIC LIGHT AND POWER AT EDMONTON, ALTA.

THE new C.N.R. shops and roundhouse are now electrical, the installation of a complete electrical power plant having been completed this week. The plant has a capacity of 125 horse-power withing the next three months. All the machinery in the repair and car shops will now be driven by current from Edmonton city service. A similar installation has recently been completed in the shops and roundhouse of the Grand Trunk Pacific at Calder, where 200 horse-power is now in use. The G.T.P. shops have also been electrified for lighting.

The addition of the two railway shops to the list of the city's customers indicates a somewhat general move on the part of local manufacturers to substitute electrical for steam power. Since last July the commercial section of the civic light and power department has installed electrical power plants totalling over 900 horse-power, including the factories and shops of the Western Canada Flour Mills, Edmonton Brewing Co., Cushing Bros.' woodworking mill, P. Burns Co., J. J. McLaughlin Co., and Edmonton Steam Laundry. The largest of these installations is that of the Cushing plant, which has 400 horse-power. A number of other firms are interested.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

SOLVING A MECHANICAL PROBLEM

By D. O. Barrett.

THE mechanism to be discussed in the following article is that of an oil engine governor. While the oil engine, itself, has no direct bearing on the subject, yet in order to fully understand some of the principles involved, an understanding of the operation of the engine will be of assistance. In this type of engine, not only gasoline and kerosene, but the heavier oils, such as fuel oils and crude oil, may be used. The fuel is injected directly into the combustion chamber of the engine, by means of the fuel pump, against some heated surface, this vaporizing the oil and firing the mixture. The timing of the injection of the oil corresponds to the timing of the ignition in the ordinary gasoline engine. These engines are governed by varying the quantity of oil which is injected into the cylinder during each working stroke. In nearly all cases, the fuel pump is operated through the medium of an eccentric located on the engine crankshaft.

There are several well-known and successful methods of governing the amount of fuel injected, but the simplest, and the one most commonly used is that in which the stroke of the fuel pump is varied to suit the load; in other words, with a heavy load, the fuel pump will have a longer stroke, while at the lighter loads the stroke of the pump plunger will be shortened in proportion. To accomplish this result, there are also several successful methods, but the one most commonly employed is that in which the eccentric on the engine shaft is moved across the shaft so as to increase or decrease its effective throw. In the discussion following, only the mechanical problems pertaining to the governor mechanism itself will be discussed and not its relation to the engine proper.

Single Arm Design

In Fig. 1 is shown an outside view of the first governor used, also the eccentric proper; and in Fig. 2 is shown a cross-section through same, from which the principle of operation may be plainly understood. As the governor arm moves out, this angular motion is imparted to the governor crank which will in turn force the eccentric in toward

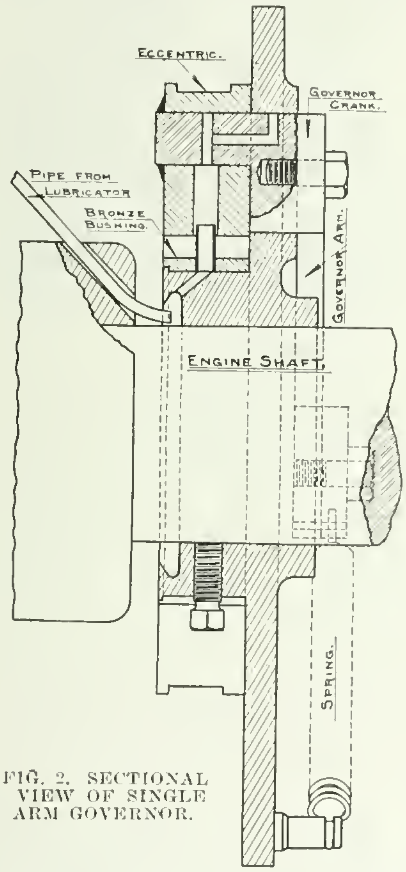

FIG. 2. SECTIONAL VIEW OF SINGLE ARM GOVERNOR.

the shaft, decreasing its throw. This governor was of fairly simple construction, as is evidenced from the few parts used. The governor plate or main body was bored out to slip over the engine shaft and was held in place by two set screws. Around the turned hub of the plate was a bronze bushing which is shown quite clearly in Fig. 8. Two opposite sides of this bushing were planed parallel to fit the inside of the eccentric. In order to maintain the bushing in position and not interfere with its freedom of movement, a groove was turned at the outer edge to conform to a slight shoulder at the end of the governor plate hub. This bushing, being open at the one side, could be spread apart slightly and then slipped over the shoulder. The eccentric was a solid casting and was machined on both sides. A groove was turned around the outer face leaving a slight shoulder on either side to maintain the eccentric strap in position, this being also of cast iron. The primary purpose in leaving the centre of the eccentric entirely open was for ease in machining, this operation being performed on the shaper. The opening, being relatively large, would, quite naturally, interfere with the lubrication of the strap to some extent, as the sharp edges would wipe off the oil.

Development of Excessive Wear

The holes for the governor crank in both the plate and eccentric were drilled and reamed directly in the castings. Over the small end of the crank was riveted a steel washer, this keeping the parts together. As the total angular movement of the governor arm from full load to no load was over 60 degrees, there was considerable wear in the crank holes both in the plate and eccentric, and these were later brass-bushed. Stock tubing was purchased one-eighth inch in thickness and, after being pressed into the previously reamed hole, was again reamed to fit the crank.

The system of lubrication is quite clearly shown in the sectional view. Around the inside of the governor plate is turned a groove, clearing the shaft sufficiently to allow the insertion of a small copper tube from the force feed lubricator; from this groove a hole is drilled at an angle up to the centre of the bronze bushing into which is tapped a short piece of one-eighth inch

FIG. 1. VIEWS OF ECCENTRIC AND EXTERIOR OF FIRST GOVERNOR WITH SINGLE CRANK ARM.

FIG. 3. VIEW OF ECCENTRIC BRIDGED, AND GOVERNOR WITH TWO CRANK ARMS.

pipe, this extending up into a larger drilled hole in the eccentric proper. As the eccentric and bushing move around the shaft in unison, the eccentric will have an in-and-out movement over the pipe. Holes are drilled through the governor crank as shown so that the oil reaches both the eccentric and the plate. This system of lubrication has worked very satisfactorily and has not been changed on any of the succeeding types of governors.

Dummy Arm Introduced

These governors proved fairly satisfactory for the ordinary run of work, such as irrigation or for factory purposes. It was found, however, that they were not sufficiently sensitive for exacting service such as electric lighting. One disadvantage which soon became evident for this class of work and especially with alternating current, was that the engine would be allowed to race or

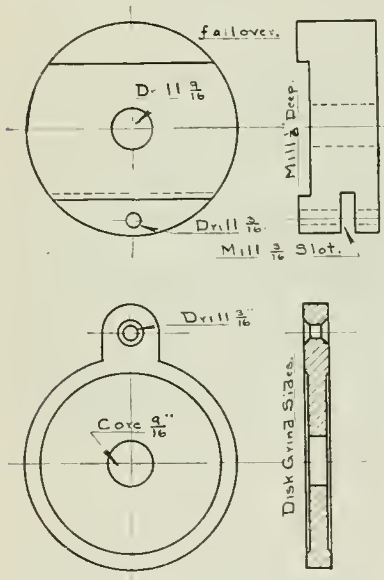

FIG. 4. GOVERNOR WEIGHTS.

"peg-leg," producing a flickering in the lights which was decidedly uncomfortable to the eyes. An effort was made to overcome this by adding a frictional device which prevented the free movement of the eccentric relative to the plate, but the relief was only temporary. Finally, another governor arm was introduced, as shown in Fig. 3; as this arm and its crank was not directly connected to the eccentric, it acted merely for balancing purposes, and was known as the dummy arm and dummy crank. The dummy crank was in reality no crank at all, but merely a straight piece slotted for the arm at the one end and provided with a shoulder at the inner end. In order that the two arms should work in unison, the central gear was placed on the extension of the plate hub and smaller gears placed over the ends of the cranks and governor arms, the same screw extending through both. These gears, in the beginning, were all of cast iron with cast teeth. Over the smaller gears were placed steel washers, these acting as shrouds to hold in the central gear. Due to sudden changes in the load, the teeth in the central gear broke quite rapidly and these were then cast of brass. The method of fastening the springs was still as shown in Fig. 1, where the outer loop was simply slipped over the end of the

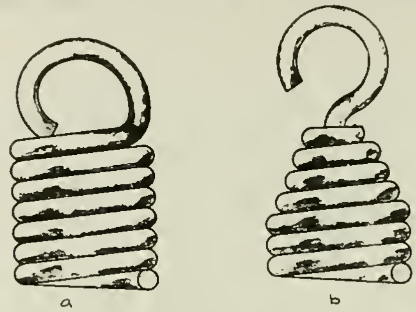

FIG. 5. (a) TYPE OF SPRINGS FIRST USED. (b) IMPROVED TYPE.

stud in which was turned a groove.

The weights used on the first governors are shown in the upper drawing in Fig. 4. These weights were quite expensive to make as they were machined all over, and were also milled-out to slip over the governor arms, these arms being of ½-in. by 2-in. cold drawn steel. A slot was also milled into the weight at the one side into which the loop of the spring could be slipped and held by a cotter pin, through the drilled hole. To change the speed of the engine, weights of various diameters were used, the thickness of the weight remaining the same. There was, thus, no adjustment directly on the spring. After the balancing arm was used, it was found that the momentary variation was taken care of, but there was still quite a drop in speed from no load to full load, due, no doubt, to the extreme distance through which the weights moved. After considerable experimenting it was found that, by attaching the stationary end of the governor spring to the end of the opposite governor arm, this condition was to a large extent remedied. To accomplish this in the easiest manner, a heavy link chain was attached to the end of spring, and extending partly around the small gears, was held in place by a small cap screw. The steel washer, formerly used on the end of the gear was replaced by a shroud cast directly on the gear. Not shown clearly in the view of the first governor was the method of keeping the eccentric and plate together; in Fig. 3 will be noticed the two cap screws which extend through the plate, and are tapped into the eccentric. Shoulder bushings are used on these screws, the plate being spot-faced for the shoulders, and also slotted sufficiently to allow for the throw of the eccentric.

After putting out a large number of these governors to operate under practically all conditions, considerable trouble was reported from the breakage of loop ends of the governor springs. Should the spring happen to break on the dummy arm, the sudden strain on the gear teeth would cause them to break, and if damage were done to the larger gear, it was necessary to remove the flywheel to replace it, so that this was more serious than might at first appear. In Fig. 5 are shown the two types of springs used. That shown at (a) would continually break at the beginning of the loop just after leaving the coil. In the later type, the loop was entirely separate from the coils, the inner end of the loop being provided with an eye around which the coils were closed. Of course, this decreased slightly the effective length of the spring, but the trouble from breakage was entirely eliminated.

Eliminating Noisy Operation

After adopting the new spring, it was found possible to change the style of weight used; as shown in the lower drawing in Fig. 4. These weights were cast in various thicknesses, three being ordinarily used. They were relieved at the centre and disk ground on the sides. The position of the weights on the arm could be changed so as to increase or decrease the tension of the springs, so that quite wide changes of speed were possible without changing the weights. Of course, only one of the weights was provided with the extension into which the spring was hooked.

After being in operation a short time, these governors became exceedingly noisy; this was occasioned from the extreme wear which occurred, due to the short bearings which were necessary on the main crank, both in the plate and eccentric, as well as on the dummy crank. The oil fuel was injected into the engine cylinder under a pressure of about 2,000 pounds per square inch, which, on a plunger of three-fourths inch diameter, gives a total pressure of nearly 900 pounds against the eccentric and strap. As this occurred at every revolution, the engine being of the two cycle type, it will be seen that the governor was subjected to extremely heavy service. Not only the brass

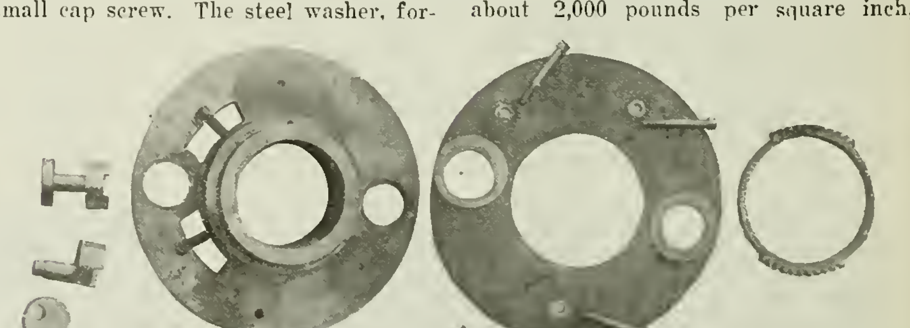

FIG. 6. FRONT AND MAIN PLATE.

bushings gave trouble, but it was also impossible to keep the shoulder bushings in adjustment; this caused a separation of the plate and eccentric at every revolution with a characteristic "knock."

The only possible solution seemed to be to arrange the cranks with a bearing at each end so that the pressure would be absorbed between these two points, thus avoiding the twisting strain which proved so detrimental. To do this it was necessary to add another plate. The main governor plate was moved to the back and the removable plate placed at the front where it would be more accessible. These are shown in detail in Fig. 6. The front plate was machined on the inside surface and bored to the same diameter as the large brass gear. The main hub still carried the same two diameters, one for the gear and the other for the bronze eccentric bushing, which was bored the same as before, but with the groove omitted, as it was securely held between the two plates. It was also possible to omit the shoulder at the side of the eccentric, allowing the strap to run freely between the two plates; this also allowed the bearing surface to be widened a corresponding amount. The front plate was fastened to the main plate by the three screws shown, around which were placed bushings of the same length as the hub, and providing a slight clearance for the eccentric and the bronze bushing. A single dowel pin was used at the centre to insure proper alignment of the plates. The plates were drilled and reamed for the cranks after being bolted together, and with the dowel pin in place.

In Fig. 7 are shown the two cranks, the method of constructing the live crank being quite clear. The outer end was placed on the crank and the two pieces inserted in a jig bored to the same diameter where the hole through the two was drilled and reamed for larger taper pin. In order to insure the throw of each being the same, both crank and end piece were finished in the same lathe fixture. The dummy crank was first made from cold drawn steel of the proper diameter, but as this material became extremely difficult to secure, it was later made from cast iron, and no breakages occurred.

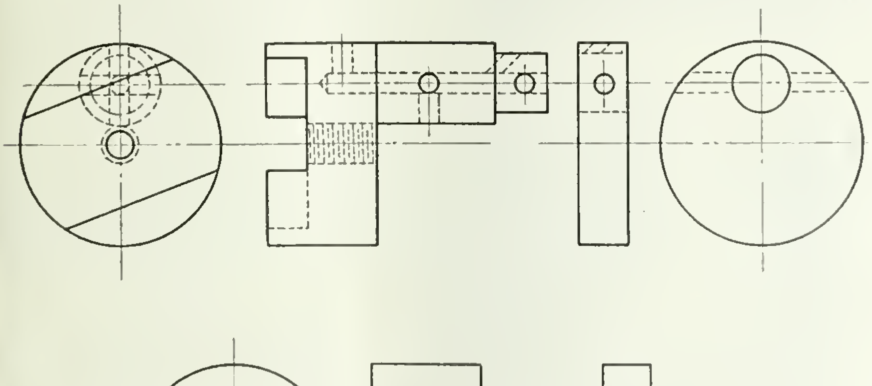

FIG. 7. CRANKS FOR DOUBLE PLATE TYPE GOVERNOR.

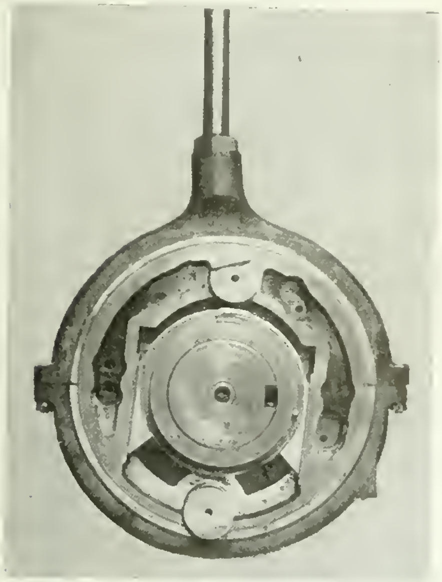

FIG. 8. ASSEMBLED GOVERNOR.

Eccentric Opening Bridged

The open portion of the eccentric was now bridged and relief for the tool cut at each end. The castings were also lightened by coring out on either side. Slots were cored sufficiently large to clear the screws holding the plates together. The bridge across the eccentric also served the purpose of holding in the dummy crank, as the inside edge never cleared the crank even at its outer position.

In Fig. 8 is shown the assembled governor with the front plate, and arms and weights removed. The eccentric strap was of cast iron, although many designers would object to the use of this metal in the above instance. Where the bearing surfaces are properly lubricated no better combination can be obtained, as is evidenced from an examination of many of the older machine tools. The two halves were cast in the one piece, and after boring and facing, were split on the milling machine, liners being used for adjustment. While the improved governor still retained the elements of mechanical simplicity, yet the many added features quite naturally increased the shop cost to a considerable extent. The results obtained in the field, however, amply repaid for any additional cast, as the replacements and repairs have been reduced to a minimum.

SIMPLE MULTIPLE CLAMPS

By F. Scriber.

IT is almost invariably an objective point in designing tools to grip as many parts as possible with the least effort, or with the least amount of rigging, but seldom is it possible to accomplish this in an effective manner, as the general run of work is of such a character as to call for a clamp on each part or its equivalent.

The purpose of this article is to describe three simple arrangements for clamping a number of pieces. Referring to Fig. 1, the illustration shows a

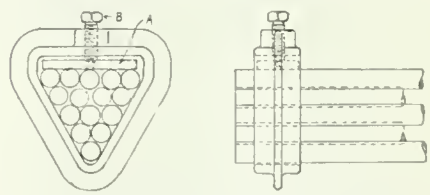

FIG. 1. VEE TYPE OF BOX CLAMP FOR GRIPPING ROUND BARS.

number of round bars which are to be cut off. These are held in what is known as a vee clamp, and the manner of using this clamp is obvious, as in gripping the work the strap A which is brought into contact with the work by the screw B, forces all the bars down until the parts are wedged one against the other and in this manner they are all held by the one screw.

A rather convenient clamp for gripping a number of flat strips of stock is illustrated in Fig. 2. In this illustration the stock is shown in section and the number of strips illustrated is eight, the clamp is made up of a number of rolls, the illustration showing fifteen, eight in the lower row which bear on the stock, and seven staggered between these rolls and the upper portion of the clamp. All of these rolls are permitted to float up and down in the clamp and are prevented from falling out by two plates, at the bottom of the clamp, upon which the lower rolls rest when the clamp is not in contact with the work, this object being attained by having pins in the lower set of rolls B, which protrude about ⅛ of an inch beyond the rolls and thus prevents the rolls from falling out of the box portion of the clamp C.

In gripping the work the nuts D on the two screws which fit into the tee slots of the machine table are tightened;

this causes the upper set of rolls to be forced against the plate E and the lower set of rolls are thus wedged against the nuts of the box portion of the clamp F, and the upper set of rolls. This con-

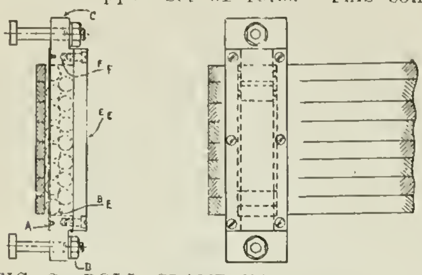

FIG. 2. ROLL CLAMP FOR GRIPPING A NUMBER OF FLAT PIECES.

struction makes a floating clamp and in this floating condition one strip cannot be bound until all of the strips are gripped. This clamp is very efficient and can be made to grip successfully quite a number of flat strips.

Having described a clamp for gripping round bars and a clamp for gripping flat bars, the concluding illustration shows a jig for drilling balls. In the lower part of Fig. 3, a ball is shown which has been drilled. In drilling these balls, it is necessary to handle more balls than what are actually being drilled. The jig used for this purpose is simple in construction and consists of the base A, which is chambered to receive the balls, In addition to this there is a plate B which contains a number of holes countersunk on the under side, the other parts of this jig are a washer C, a binding nut D, and a screw E.

Having arranged the balls in the chamber of the jig in the manner shown the ring is placed over the screw and is tightened by the nut. In doing this a number of balls are centralized in each countersunk hole until all the balls are clamped in place, when we proceed to drill in the usual manner using the holes through the plate to guide the drill through the centre of the ball.

While primarily these three parts, namely Round Bar, Flat Bar, and the Ball, are parts which can be easily machined one at a time, with the tools

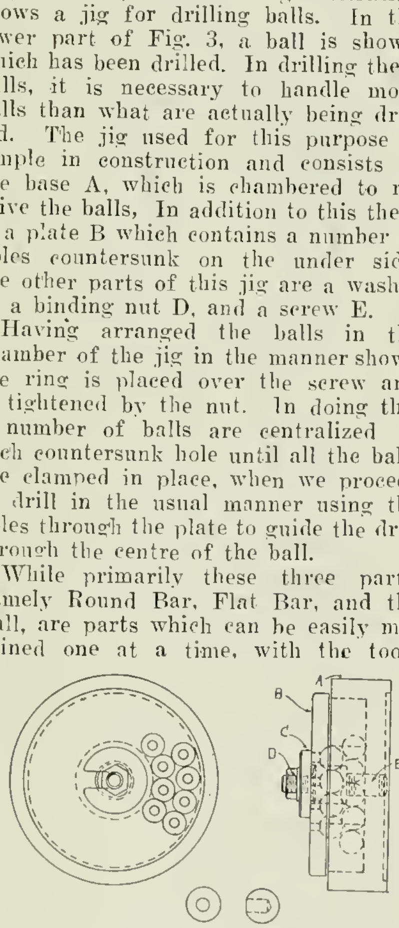

FIG. 3. JIG FOR DRILLING HOLES IN BALLS AND SHOWING BALL AS DRILLED.

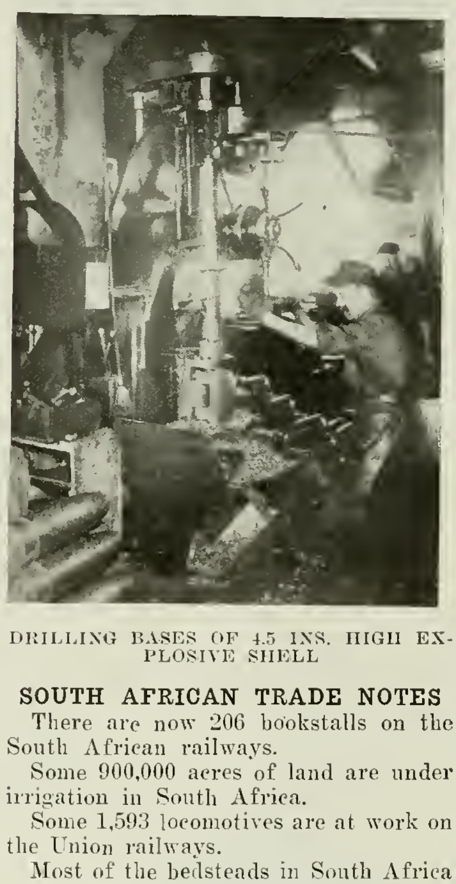
shown, the various illustrations make it evident that these parts can also be machined in quantities even more economically.

DRILLING BASES OF 4.6 INS. H.E. SHELLS

By R. Hamilton

WHEN the manufacture of 18 pdr. high explosive shell was being discontinued, many firms were somewhat at a loss as to the disposal of much of their equipment. Where machinery could be adapted to the production of the heavier shells the problem was easily solved, but to find a satisfactory use for the heavy upright drills required special ingenuity on the part of plant executives. The accompanying cut shows a Foote-Burt drill fitted up to bore out the base of the 4.5 inch high explosive shell. A special swing clamp chuck is secured to the table of the drill press; the upper end being fitted with a ring plate to steady and align the cutter while operating. The cutter is of the multiple type removing all the metal at one sitting. Three of these drills have been equipped in this manner and their average production is about 160 shells per day.



DRILLING BASES OF 4.5 INS. HIGH EXPLOSIVE SHELL

SOUTH AFRICAN TRADE NOTES

There are now 206 bookstalls on the South African railways.

Some 900,000 acres of land are under irrigation in South Africa.

Some 1,593 locomotives are at work on the Union railways.

Most of the bedsteads in South Africa come from the United Kingdom.

Facilities for handling coal at the Cape Town docks are to be materially increased.

The largest explosives works in the Cape Province pays over $500,000 a year in wages.

The gold industry of South Africa distributed in 1915 over $67,500,000 in wages and salaries.

One Natal firm is now treating 50 tons daily of green bark in the manufacture of wattle extract.

The railways now being operated in what was German Southwest Africa have a total length of 1,521 miles.

The total value of the gold output of the Witwatersrand since discovery to the end of 1915 was $2,270,000,000.

There is a good business done in Cape Town in the construction of motor-car bodies and side-cars for motor-cycles.

The National Bank of South Africa, Ltd., have now opened branches at Mombasa, Nairobi, Tanga, and Dar-es-Salaam.

All ordinary harness is now being made in South Africa. This is a local industry which will probably show surprising growth.

The demand for heavy boots in South Africa is increasing enormously now that the natives are generally adopting footwear.

In normal times, Joburg drew a lot of its sugar from Mozambique, but the bulk of the crop has now been diverted to London.

At Blantyre, Nyasaland, the cotton and tobacco markets are strong, rubber is stationary, and tea is lower than it was early last year.

It is expected that the production of citrus fruit within the Union will reach 1,000,000 boxes in 1917. The export trade is steadily growing.

Cape Town has ample funds in hand to meet all capital expenditure for some years. The new drainage and water schemes will involve contingent liabilities.

The Livingstone (Northwest Rhodesia), Farmers' Co-operative Society are now responsible for the purchase of all implements, dips, salt, grease, oil, etc., required by members.

Much South African cheese is finding its way to the Joburg market now, and, owing to the gradual improvement in the make it is largely taking the place of the Dutch imported article.

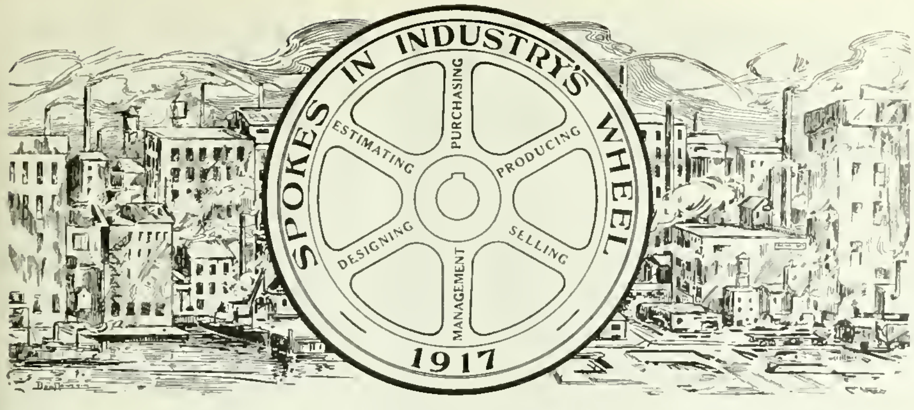
As indicating the commercial importance which British East Africa is assuming, no fewer than 34 travellers' licenses were issued at Nairobi during the quarter ending September last.

The cost of iron and steel, Baltic timber, and galvanized iron, imported from oversea for the use of the South African railways has increased 100 per cent. during the war. Pitch pine is 150 per cent. dearer.

A few years ago, South Africa imported annually $1,600,000 worth of butter and $500,000 worth of cheese. Imports of cheese are now diminishing, and the imports and exports of butter nearly balance.—British and South African Export Gazette.

CYANIDE IN CANADA

AT the meeting of the Society of Chemical Industry in Montreal recently, a report on the cyanide situation, important to the gold mines of the country, was read. It was shown that this important chemical could be made available in Canada, and the hope was expressed that some of our Canadian manufacturers would avail themselves of the shortage in the market to establish plants in Canada. Mr. Wardleworth, chairman of the Canadian section, stated that word had been received by Sir George Foster from the British Government to the effect that enough cyanide to keep the mines going would be exported to Canada provided the shipping facilities permitted.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

KARL E. BARRETT

IT was among the green hills of Vermont-State, in the town of St. Johnsbury on the 4th day of October, 1886, that Karl E. Barrett, superintendent and chief engineer, E. & T. Fairbanks Co., Sherbrooke, Que., was born. Being born and brought up in the town which is the home of the Fairbanks scale, it is not strange that we find him to-day an expert in scale design and manufacture.

In 1903, after leaving the public schools, he started his technical training in St. Johnsbury Academy, from which he graduated in 1907, ranking high in his studies as well as in athletics. He had been captain of both the baseball and basketball teams, and, through his enthusiasm and determination, winners in both cases had been placed in the field.

He took his first business appointment by engaging with the E. & T. Fairbanks Co., during his summer vacation in 1905, being employed in their valve department. Although but 19 years of age, he applied himself so efficiently in operating the turret lathes on the manufacture of valves that his efforts showed increased production comparatively; consequently when an operator was off on his annual holiday, Barrett was given the particular machine to run during the interval. When given these opportunities, he did not content himself with turning out the same production as the regular operator, but put his entire energy and resourcefulness into increasing the output where possible. In this way he made a reputation for himself during the two summers devoted to this work and showed that he was as big as the jobs given him. After graduating in 1907 he started to serve a two year's apprenticeship with the Fairbanks Co., on the manufacture of scales. Having his mind made up however, to become a mechanical engineer, and not being financially equipped to enter college, he set out to obtain by long hours of hard study what knowledge he would have secured could he have entered a college for training.

When he had served his apprenticeship in the shops, he was given an opportunity in the engineering department, and while there his shop experience and the engineering knowledge being acquired soon won distinction for him; as a result, after six months time, he was advanced to that branch of the engineering department which handled the designs of scales for Foreign Countries, as also scales for special purposes. While serving in this department he compiled original data relating to scale designs, also data on the Section Moduli of rectangular forms which he submitted to *Machinery*, of New York, for publication. After this data had appeared in that journal, it was found so useful to designers that it was given four pages in *Machinery Handbook*, published by the Industrial Press, 53,000 copies of which have been sold.

KARL E. BARRETT.

During the fall of 1911, he was transferred to the E. & T. Fairbanks Co., plant at Sherbrooke, Que., in order to institute and take charge of an engineering department there. With a view to developing a higher grade quality of mechanic, and to foster a greater intimacy with scale manufacture, Barrett started a night school during the winter of 1912, at which, every Monday night, from 75 to 100 employees gathered for instruction. Here they were taught the reasons for the different operations in the shop, how and why these should be carried out as directed, and concerning the part each piece played in the welfare of the scale. A small model for demonstration purposes, one-twelfth (1-12), actual size was built by our "Spoke" in his spare time illustrative of a 20 ft. two section track scale, from which, when finished and erected, and a miniature loaded freight car run on, actual weights were obtainable.

In 1914, Mr. Barrett was given the title of Chief Engineer; his systematic handling of the work in that capacity resulting in the establishment of an efficient engineering department. Among the new designs of scales developed by him for special weighing purposes might be mentioned the 300 lbs., Even Balance Shell Scale for weighing the 6 ins., 8 ins. and 9.2 ins. high explosive shell. This apparatus, we are informed, represents a remarkable achievement in scientific scale construction, enabling the operator to weigh three shells per minute by the rolling process. The scale being provided with a relieving attachment is preserved from hard use due to the impact of the shell as it rolls on-to and away from the platform, thus ensuring maximum life to the various component members, and enabling the sensitiveness of the mechanism as a whole to be retained. The scale when fully loaded is sensitive to 1 dram. A similar design of scale is manufactured for weighing 18 pdr. shrapnel, 4.5 ins. and 60 pdr. high explosive shells. Our "spoke" was appointed Superintendent, in addition to Chief Engineer, in 1916.

Mr. Barrett's pleasures in life are shared by his wife, who became Mrs. K. E. Barrett, 8 years ago. Outdoor sports claim a place in his life, as he enjoys motoring, fishing and hunting. To Y.M.C.A. work he devotes much of his spare time. His fraternities are Passumpsic Lodge, No. 27 A. F. & A. M.; Haswell Royal Arch Chapter No. 11, R.A.M., Palestine Commandry, No. 5 K. T.; and Mt. Sinai Temple No. 3 A.A.O. N.M.S., the third oldest shrine temple in North America.

Mr. Barrett attributes his success to the systematic reading and study of technical and industrial magazines, and technical books. He encourages his men to do likewise and makes a point of seeing that they take copies of such publications as bear both directly and indirectly on their work and welfare. He is strong in his encouragement of men to take Correspondence School Courses.

MECHANIC'S INSTRUCTION COURSE—XIV

By J. Davies

IN some cases there are two gears built into lathe, which are practically fixtures, one on lathe spindle and the other gearing with it inside the frame; there gears are never or very rarely removed and must be taken into consideration in figuring out the gears. When a lathe is made with a pair of gears that are not intended to be removed, they are invariably made a definite proportion to each other usually 2 to 1 or perhaps 3 to 1. In cases of this kind the easiest and simplest way to work out change gears is to multiply the number of threads per inch in guide-screw, by the ratio of the two fixed gears, proceeding as mentioned in previous articles.

Example: Find wheels to cut 6 threads per inch with a leading screw 5 threads per inch, with a fixed wheel on the lathe spindle of 30 teeth, gearing with a wheel containing 60 teeth. The ratio of the fixed wheels is 30/60 or 2 to 1. Rule: multiply threads in lead screw by ratio of gears 5 $\times$ 2=10. Ignore the fixed gears from now on, and assume that the leading screw has 10 threads per inch, proceeding as before. Thread to be cut 1/6, lead screw 1/10 invert and multiply

$$\frac{1}{6}\times\frac{10}{1}=\frac{10}{6}=\frac{100}{60}$$

If the pitch to be cut is exceptionally difficult or if you are doubtful as to whether you can get any combination to cut the pitch required try this method of using prime numbers.

Prime Numbers and How to Find Them

This method of finding prime numbers or excluding the numbers that are not prime was invented by Eratosthenes 194 B.C. and is called Eratosthenes' sieve. To find the prime numbers in any series of numbers write in their proper order all the odd numbers contained in the series. Then reckoning from 3 place a dot over every third number in the series; reckoning from 5 place a dot over every fifth number; reckoning from 7 place a dot over every seventh number, and so on—the numbers remaining without dots over them together with number 2 are the prime numbers and cannot be divided by any other number.

Example: For a series of numbers up to 40, write down all the odd numbers in their order 1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, 27, 29, 31, 33, 35, 37, 39. Start to count at No. 3, placing a tick over every third figure and so on as explained, the number unticked are 1, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, these together with No. 2 are the prime numbers. The following table of prime numbers will be found very useful:—

1, 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89, 97, 101, 103, 107, 109, 113, 127, 131, 137, 139, 149, 151, 157, 163, 167, 173, 179, 181, 191, 193, 197, 199, 211, 223, 227, 229, 233, 239, 241, 251, 257, 263, 269, 271, 277.

Application of Prime Numbers

Required, wheels to cut .654 in. pitch, with a lead screw 3 threads to the inch: (1) Find ratio according to preceding rule, $\frac{.654}{1000}$=Pitch to be cut. $\frac{1}{3}$=Pitch of lead screw. Invert pitch of lead screw, and multiply, $\frac{.654}{1000}\times\frac{3}{1}=\frac{1962}{1000}$=Ratio. Take the numerator and divide it by the least prime number given in the table as many times as you can. Then by the next prime number and so on until you have exhausted the possibilities of further division; you have then got all the factors contained in that number: 1962÷2=981; 981÷3=327; 327÷3=109.

2$\times$3$\times$3$\times$109=1962.

Treat the denominator in the same way.

1000÷2=500; 500÷2=250;
250÷2=125; 125÷5=25;
25÷5=5.

2$\times$2$\times$2$\times$5$\times$5$\times$5=1000. In this example one of the factors is 109. It would therefore be impossible to cut the above pitch without a gear containing 109 teeth or a multiple of 109, as by referring to table of prime numbers we see that 109 is a prime number and cannot therefore be further divided.

Having found all the factors, arrange them into an equal number of groups for the driving and driven wheels, using as many wheels as is most convenient

$$\frac{(2X3\times3)\times109}{(2\times2\times2\times5)\times(5\times5)}=\frac{18X109}{40X25}.$$

An 18 wheel would be too small, so multiplying by 2= $\frac{36\times109}{80\times25}$ wheels required.

Here is another example which is taken from actual practice. It is required to cut a thread .7854 in. pitch with a leading screw ½ in. pitch. Proceed according to rule $\frac{.7854}{10000}\times\frac{2}{1}=\frac{15708}{10000}$ ratio.

Using prime numbers to collect factors, take the numerator first:

15708÷2=7854; 7854÷2=3927;
3927÷3=1309; 1309÷7=187;
187÷11=17.

2$\times$2$\times$3$\times$7$\times$11$\times$17=15708.

Collect factors of denominator the same way:

10000÷2=5000; 5000÷2=2500;
25000÷2=1250; 1250÷2=625;
625÷5=125; 125÷5=25;
25÷5=5.

2$\times$2$\times$2$\times$2$\times$5$\times$5X5X5=10,000.

From these factors a number of different sets of gears can be obtained. Arrange them in any order and in any number of groups, taking care not to alter their relative values:

$$\frac{(2X2)X(3X7X11X17)}{(2X2X2)X(2X5X5)X(5X5)}=\frac{4X51X77}{8X50X25}$$

multiply the 4 and the 8 by ten = $\frac{40\times51\times77}{80\times50\times25}$ wheels required.

Cutting Millimeter Pitches With Inch Guide Screws

As given in most text books, 25.4 millimeters=1 inch, or one millimeter= $\frac{1}{25.4}$ of an inch, multiplying by 5 to get a whole number $\frac{1}{25.4}\times5=\frac{5}{127.0}$ in. According to Government standards, the error in this fraction is less than 1-10th of one thousandth of an inch, so that for all practical purposes this standard can be considered as absolutely correct.

To find wheels for millimeter pitches, first find fractional parts of an inch by multiplying the number of millimeters by $\frac{5}{127}$ then proceed exactly as before. Example: (1) required wheels to cut 10 millimeter pitch with a lead screw 4 threads to inch. $\frac{5}{127}\times\frac{10}{1}=\frac{50}{127}$ in. pitch of screw to be cut. Invert pitch of lead screw and multiply

$$\frac{50}{127}\times\frac{4}{1}=\frac{200}{127}=\frac{2\times100}{1\times127}=\frac{80\times100}{40\times127}.$$

It will be seen by reference to table that 127 is a prime number and cannot therefore be further divided, so that the only change necessary to adapt a British lathe to cut millimeter pitches would be to have a special wheel of 127 teeth. Example: (2) Find wheels to cut 7 millimeters with a lead screw ½-in. pitch. $\frac{5}{127}\times\frac{7}{1}=\frac{35}{127}\times\frac{2}{1}=\frac{70}{127}$ wheels required.

In exactly the same way inch pitch threads can be cut on a lathe with a metric leading screw. Example: It is required to cut 8 threads to the inch on a lathe with leading screw 10 millimeters. Thread to be cut ⅛-in. pitch. Pitch of leading screw $\frac{5}{127}\times10=\frac{50}{127}$. Invert and multiply, $\frac{1}{8}\times\frac{127}{50}=\frac{127}{400}=\frac{1\times127}{4\times100}=\frac{20\times127}{80\times100}$.

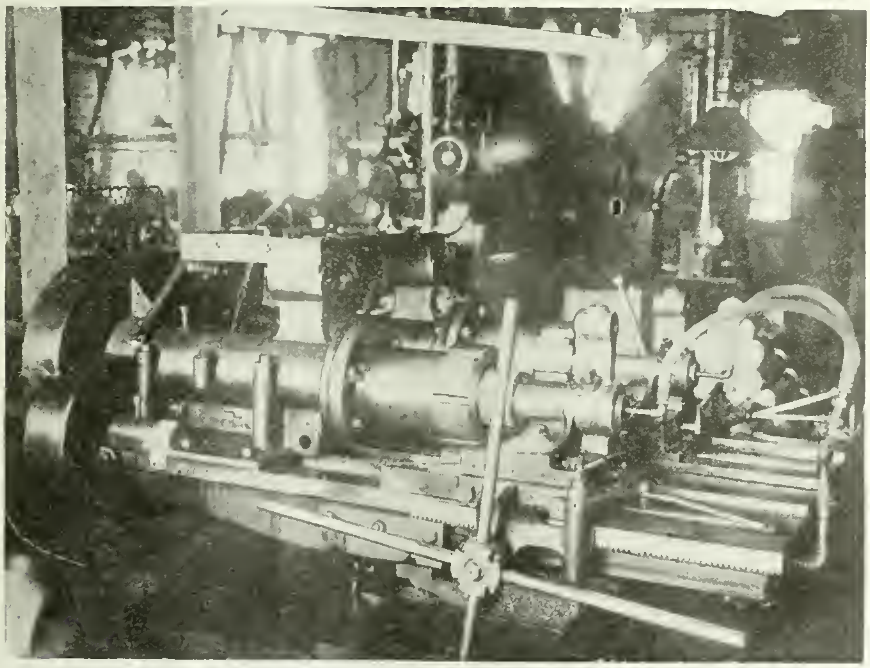
It may happen that after working out a set of gears it is impossible to gear them up. A simple method of testing whether a doubtful set of gears can be used or not, is with a rule and a small pair of compasses. Take an ordinary rule and let each 1/8-inch represent 10 teeth; draw circles to this scale, of all the wheels intended to be used, in their relative positions, and it will be seen at once whether the wheels can be geared up or not.

Do not mesh the wheels too deeply. Many mechanics have an idea that the wheels must be meshed tightly to prevent backlash; this is a mistake and is a very fruitful source of broken teeth.

IMPROMPTU SHELL BORING MACHINE

By C. M.

SPECIAL shell machinery is undoubtedly the feature of present day activity, and hardly a week goes by without the advent of some addition to the large variety of tools now used for shell operations. In connection with these developments, the cut herewith may be of special interest, not as a new departure, but as featuring a Bertram shell boring machine designed originally for service on the production of the 18 pdr. H. E. projectile. The machine here shown has been overhauled and adapted for rough boring 4.5 inch, mark VII. shell. The machines have two spindles operating at the one time, the companion to that shown being designed so that each spindle can be operated independently; providing thereby increased facility for more rapid production. These tools are only used for roughing out the parallel portion of the bore, the finishing being completed on other machines. The lubricant is forced through the bar in sufficient volume to wash the cuttings clear. Automatic stops are provided, and only one man is required to keep the four spindles in constant operation. The two machines produce approximately 250 shells per day.



IMPROMPTU SHELL BORING MACHINE.

FRENCH SUPPLIES OF RECONSTRUCTION MATERIALS

THE U.S. Commercial Attache C. W. A. Veditz, Paris, in a report to his Government published in the Commerce Reports, states that the French Minister of the Interior has just published the results of an investigation made under his direction concerning the supplies of building materials likely to be available for reconstruction work in France upon the conclusion of peace. Among the materials thought to be available in sufficient quantities are stone, brick, sand, cement, tile, building hardware, wall paper, and certain others of minor importance. It is believed that, for lime, iron pipe, street-paving materials, and sandstone, French production may be increased to a point that will meet the demands. In the groups of materials in which a shortage may be felt are plaster, timber and lumber, slate, structural iron and steel, heavy hardware, tin, zinc, lead, plumbing supplies, pumps, sanitary appliances, heating apparatus, paint, and glass of all sorts.

It is reported by the Government that the necessary steps will be taken promptly to encourage the larger production of those materials of which there will undoubtedly be a very considerable need as soon as building operations are resumed on a large scale. These measures consist mainly of: The provision of facilities for obtaining the necessary equipment for producing building material; the resumption of operations in plants that were shut down; the resumption of the exploitation of mines and quarries; the reopening and improved equipment of brickyards, tile works, and establishments engaged in the manufacture of lime and cement and other basic building materials; finally the adoption of measures to increase the available supply of labour. It is, furthermore, stated by the Government that every effort will be made to have the work of reconstruction undertaken as far as possible by local concerns. It is of course generally understood that the Government will give financial assistance to all manner of reconstruction work in the devastated regions of France.

RUSSIA BUYING IN CANADA

RUSSIA will hereafter be represented in Canada by a Commissioner authorized to make purchases of war supplies of various kinds here on behalf of his country. The Commissioner, Col. Kovaleff, has arrived in Ottawa, and is opening up offices. Russia has been making large purchases of munitions and other materials on this side of the Atlantic through the Russian Supply Committee, whose president is General Zaluboffsky, and whose headquarters are in New York. She has, moreover, obtained a considerable quantity of goods, munitions and freight cars required in her military operations.

The Canadian Government has made representations to the Imperial Russian Government as to the opportunities for supplying its requirements to a greater extent by purchases in Canada and the advantages of trade between the Allies. Its efforts have been rewarded by the appointment of Col. Kovaleff, which is an event of importance to Canadian producers. The Canadian Government will give the Russian Commissioner all possible assistance in his work.

CANADA'S TRADE INCREASES RAPIDLY

CANADA'S trade for the month of January, according to a return issued at Ottawa on Feb. 20, increased by \$38,000,000 over January last year. Total trade for the month was \$177,946,907. Total trade for the ten months of the fiscal year amounted to \$1,878,284,697, an upshoot of approximately \$718,000,000 over the corresponding period of 1915-16.

January imports totalled \$72,323,074; increase, \$22,000,000. Ten months' imports, \$674,964,548; increase, \$280,000,000.

January exports, \$99,106,259; increase, \$16,000,000. Ten months' exports, \$1,203,320,149; increase, over \$437,000,000.

The big item of increase in domestic exports was agricultural products, which in the ten months grew from \$217,909,912 to \$340,002,369, and manufactures, which increased from \$166,414,552 to \$368,655,496. Of coin and bullion, which are computed in the grand total, the imports were \$2,928,278 in January and \$2,592,701 in the ten months, while the exports were \$1,423,489 in January, and \$196,200,607 in the ten months.

In the same period, mineral exports increased by seventeen millions to seventy millions, fish by two millions to a total of \$20,860,000, and forest products by four millions to \$49,833,800.

Safe Practice at Blast Furnaces and Its Development-V.

By Frederick H. Willcox

In its efforts to increase safety in the metallurgical industries, the Bureau of Mines, Washington, D.C., has been studying the causes of accidents at blast furnace plants also methods for their prevention. This article describes the known dangers and makes suggestion of means whereby the risk of accident may be lessened or, better still, wholly avoided.

PIPPE FITTERS AND TUYERE GANG

Do not go up on the bustle pipe or stack platforms until you have notified the blower, keeper, or stove tender. When going above the bustle pipe it is safest to have a watcher. Before repairing sprays on dust catchers or on skips, skip-pit siphons, steam, air, or oil lines on top of the furnace, or sprays on the furnace jacket, notify the furnace foreman as it may be necessary to stop charging or to check the furnace.

FIG. 38. WORKMAN THROWS DOWN BOARD WITH NAILS IN IT.

Leaking steam, where the men have to work, is always annoying and is frequently a menace on account of the noise and the mist, and the possibility of scalds. You can do much to prevent the danger from this cause by promptly attending to the leaks. Warn other men of the danger of attempting to stop steam leaks on pipes under pressure by tightening flanges.

A blast-furnace plant is different from other plants in that, if an emergency requires a quick shutdown, the operation may be very hazardous, unless everyone knows what to do and does the work assigned to him promptly and accurately. Make it your first duty to learn the layout of the water and the steam lines leading to the gas mains, and the water lines leading to the water-seal valves. It is up to you to see that these lines are always in working order. Try them frequently by testing the steam line to the main for gas, and, if the line is plugged, clean it. Try the lines from the water and also from the steam supply for delivery; keep them drained to prevent freezing, and be sure the valves are not stuck. Do not let the water collect in the water-seal valves.

Successful and safe furnace operation depends in part upon the cooling-water system being kept in proper condition. Careful testing of tuyeres, coolers, plates, regularity in flushing the mud and sediment out, and regular inspection of the strainers, will do away with much of the disagreeable, difficult, and, at times, dangerous work caused by chilled or slipping furnaces, "messes," and bursting tuyeres due to water leaks.

Bricklayers

Inspect a scaffold before going up on it, and do not let your helpers or laborers go up unless you are satisfied that the scaffold is safe; many of them probably do not know whether it is safe or not, and must rely upon your judgement. In piling brick on a scaffold be careful not to overload it. Don't permit your helpers to drop the bricks on the flooring; make them set the bricks down carefully, and don't let buckets of clay or loads of bricks down heavily. Avoid overloading the hoist buckets, so that the material can not fall off; use safety hooks for hoisting buckets and pails. Don't throw brickbats down promiscuously when you are on a repair job; rope off a danger place, and place a danger sign to warm the men. Be careful not to leave your tools or bricks where they can be easily dislodged and fall, whether there are men below or not.

Before going into inclosed places where gas has been used or contained satisfy yourself that the gas valves are tightly shut. Remember that in such places there is always an odor of gas unless ventilation is very ample and pronounced. It is sometimes necessary to go into these places, and although you may feel assured that there is no gas leak, come out at once if you begin to feel dizzy or ill. Gas may come from old brickwork, flue dust, bulkheads, or wet surfaces in amount sufficient to overcome you, and when ventilation is difficult the slightest odor of gas is a warning for you to exercise the greatest caution. Always wear a belt and life line and a breathing apparatus where ventilation is weak or lacking and there is reason to expect gas. Use electric lights when working inside gas mains; torches make the air unfit to breathe. Use goggles when you are cutting brick, and if you get a bruise, abrasion, laceration report it at once.

Carpenters

It is your duty to use sufficient and strong enough lumber to make every scaffold, staging, railing, gangway, and ladder safe. The men may not know whether they are safe or unsafe; but whether they are competent or incompetent to judge, you can not evade responsibility for unsafe construction. Temporary ladders, runways, and other wooden constructions not intended for permanent use often are used when they have become unsafe. Make it your duty to condemn any unsafe equipment of this kind and to promptly remove temporary scaffolds or ladders when the need for them has passed.

Avoid leaving lumber with projecting nails about the plant, and hammer flat or remove all projecting nails that you notice on scrap lumber or lumber used in construction. (See Figs. 38 and 39). In laying planks for temporary floors, walks, or runways place the ends so that men in stepping on them will not tip the planks up.

Most of the accidents that happen to men doing carpenter work are caused by their hitting themselves with hammers and hatchets, from saws slipping, and in handling lumber. In working on lumber piles watch that you do not fall. In handling rough, heavy, or splintered lumber be careful not to drop it on your

FIG. 39. RESULT OF LEAVING BOARD LYING ABOUT WITH NAILS IN IT.

hands or foot or lacerate your hands. Be watchful and careful in the use of hand tools, and observe danger signs and the directions and warnings of foremen acquainted with the dangers at the different parts of the plant. By so doing a large proportion of the injuries commonly encountered will be avoided.

FIG. 40. SAFE WAY TO OPEN A SWITCH. USE ONE HAND AND KEEP OTHER BEHIND BACK.

Electricians

The insulation on electric wires and on tools and rubber gloves can not be depended on to prevent shock, as the insulation may not be in good condition. Do not work on live circuits unless absolutely necessary, and if necessary and you are in doubt as to the voltage of the circuit, consult the foreman and obtain his permission.

Try to observe the following precautions: Use only one hand if possible (Figs. 40 and 43): work on only one wire at a time and insulate it before starting on the next one; insulate parts of opposite polarity within reach of tools; do not touch electric conductors when you are standing on iron plates, structural iron, wet ground, or pavement—get a dry board or rubber mat to stand on; use tools with the handles adequately wound with tape, and wear rubber gloves without cracks or holes. Take the same precautions with supposedly dead circuits, as there is always a chance of such circuits being crossed with a live circuit. Low-voltage system, telephone wires, and signal wires may similarly be crossed with high-voltage lines.

When power has been cut off by opening a switch place a danger sign bearing your name on the switch and lock it open. Do not remove the sign and lock unless the work is completed, everybody and everything clear of the circuit, and no one in a position to be injured by the machinery starting up. Do not attach wire or cord for lights to iron pipes or structural parts. Neglect of this precaution may lead to charging of equipment or parts so that a man may receive a shock when least expected. Make frequent inspection of flexible cord for hand lights, portable clusters, or electric drills. The various crews frequently handle them when standing on wet places where, should the insulation be defective, a serious burn or shock might result.

Remove all dead circuits not likely to be used. Avoid installing temporary wires in a slipshod manner. Do not let inexperienced men handle electrical equipment, and do not set bad examples of careless familiarity with electrical equipment for inexperienced men to follow. Always attend immediately to an electric burn. Such burns are often misleading; a third-degree burn which may not be immediately painful may later result in gangrene.

Cranemen

Never carry a load over a workman's head. If men are working in the path of a load, run the trolley out to avoid them, or give them warning. Before moving a crane be sure that no one is in a position to be injured. Open the main switch before leaving the cab, and do not go or allow another to go on top of the crane runaway without opening the main-line switch and attaching to the switch a notice bearing his name. If the switch is found open and no notice on it, notify the foreman instead of shutting it yourself; there may be a reason for its being open.

Do not hoist without a signal when men are hooking on or slinging material. If possible be sure that their hands are not inside the hook or sling. Place the trolley directly over the load to avoid swinging it against the workmen. In hoisting heavy loads test the brake when the load is a few inches clear of the floor.

After a repair job is finished go over the crane carefully and pick up any tools, bolts, or parts left behind. Watch for loose parts; see that the brakes, warning bells, and switches work properly and report at once insecure or dangerous parts or places. Don't leave chains, hooks, or buckets hanging at heights that do not clear a man's head.

Notes on First Aid

In plants where the continual presence of a doctor or nurse is not feasible it is advisable to have at least one emergency first-aid box. These boxes are furnished by various manufacturers and associations and contain materials designed or recommended by advisory boards of physicians and by the American National Red Cross. They are admirably adapted for use at isolated plants and primarily are for the prevention of infection. A first-aid box in the charge of the chemist, storekeeper, or watchman will encourage the workmen to form the habit of seeking immediate first-aid treatment for slight injuries. Such treatment, if correctly performed, may prevent infection or illness, but further treatment should be by a physician.

When a man is so badly injured that he needs immediate relief before a physician can arrive or before he can be taken to the first-aid room it is essential that some one with a knowledge of first-aid should assume charge, preferably the foreman, first-aid man, member of safety committee, or ranking employee and direct the work of caring for the injured man until the doctor arrives.

Transportation of Injured

Do not move an injured person or move any part of his body until you are sure of the nature of the injury. If the injured man is unable to walk use the greatest care in placing him on the stretcher. Stretchers are now so universally available at plants that mention of other means of carrying men should be unnecessary; however, familiarity with methods of handling injured men is essential.

Eye Injuries

Any object in the eye that irritates the lid or eyeball probably makes a cut which may be infected just as easily as a cut on the hand or foot, and more so if a toothpick, match, knife, or handkerchief is used to remove the object. Moreover, infection of a wound in the eye is a very serious matter, because the eye is the most delicate external organ of the body. If any injury to the eye is neglected or wrongly treated, not only may the eye become inflamed, involving loss of time, but the sight may be lost. If you get something in your eye, do not try to remove it from the eye at your

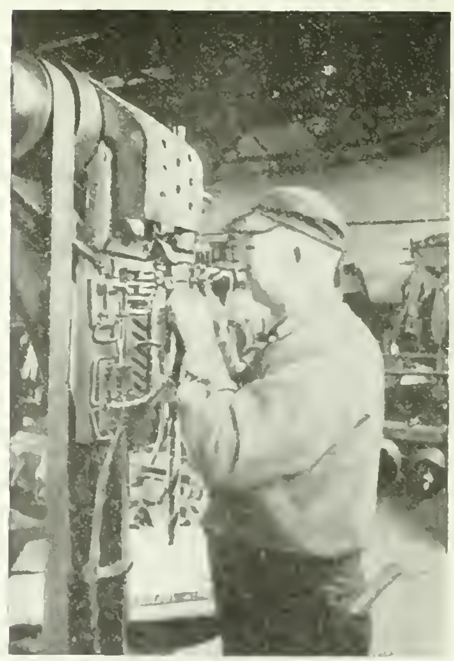


FIG. 41. ELECTRICIAN REPAIRING WIRES WITH SWITCH IN; A DANGEROUS PRACTICE.

working place; go to the first-aid station and have your eye examined at once. If the object can not be removed by cotton rolled on the end of a match or toothpick or by a loop of sterile horsehair, it is probably imbedded in the eyeball or eyelid, and the injury should be examined by a physician immediately.

FIG. 42. RESULT OF REPAIRING WIRE WITH SWITCHES IN. SHORT CIRCUIT BURNS ELECTRICIAN.

Cuts, Lacerations, and Punctures

Whenever the skin has been cut accidentally, it is safe to assume that germs have been introduced, because tools, clothing, or other material, the dust in the air, or the skin itself may carry disease germs. Every wound should be primarily looked upon as infected and receive immediate attention. A fresh cut should not be washed, even by the first-aid man; leave that for the physician. Unsterilized water is dangerous, for it may contain infectious germs. For the same reason waste, cobwebs, tobacco, or dust should not be put on a wound, nor should the open wound be touched with the fingers.

If a fellow workman gets hurt and the wound bleeds profusely, or in spurts, apply a tourniquet or constrictor and notify the first-aid man. Immediate first aid by fellow employees is imperative in such cases, as the man may bleed to death before the first-aid man can arrive. A belt, suspender, handkerchief, rope, or any immediately available material that can be tied with a knot and twisted will do for a tourniquet. The man should be made to lie down and the injured part be kept elevated as high as possible by some one. If a limb is crushed or badly mangled, the tourniquet should be placed above the knee or elbow, near the crotch or arm pit, and twisted until just enough pressure is obtained to stop the blood. Every 20 or 30 minutes the tourniquet should be loosened a little; if bleeding recommences, it should be tightened again. If the circulation is stopped completely for upwards of three hours gangrene may develop. Many severely bleeding wounds may be stopped simply by pressure in the wound with a clean bandage.

Puncture wounds, such as are caused by nails, slivers, and small sharp objects are perhaps the most dangerous of all small wounds. Such cuts are always larger on the inside than on the outside on account of the elasticity of the skin, and the danger of infection is greater because the puncture closes, little bleeding occurs, and there is less chance of any dirt and germs that may have gotten into the wound being flushed out by the flow of blood. Puncture wounds of the foot, and the palm of the hand, the thumb, and the little finger are especially dangerous.

Burns

A burn is not readily infected when first inflicted unless it has been broken open accidentally or by careless or improper handling. A burn should not be washed by anyone except the physician. For small burns picric-acid gauze or sterile gauze with vaseline spread on it, placed over the burn and fastened with a roll bandage, is efficacious. The use of carron oil, which is a mixture of linseed oil and lime water, is not recommended. Soda and sterilized water may be used, but is not as soothing to burns as picric acid.

When a large burn is caused by clothing ignited from hot metal or cinder, or by electric flashes, steam, or boiling water, it is better not to remove any but the outer clothing. The injured man should be handled as little and as carefully as possible. It may be necessary to cut away part of the clothing, such as a sleeve or trouser leg. In case medical or hospital attention is not immediately available, the entire burned area should be covered with picric-acid gauze or vaseline-covered gauze. If a hospital is near, the clothing may be saturated with a soda and water solution (one-fourth pound soda in a half gallon of clean water). After such treatment, the injured person should be wrapped closely in a blanket.

FIG. 43. SAFE WAY TO REPAIR A WIRE; SWITCHES OUT.

All burns should be reported immediately to the foreman or first-aid man. Sometimes a second or third degree burn—that is, one in which the inner and outer skin, or skin and flesh beneath, are destroyed—may not, although a serious burn, be immediately painful, but later may lead to gangrene.

Fractures

For the purposes of first-aid, fractures may be classified as "simple," when the broken bone does not come through the skin, and "compound," when the broken bone sticks through the skin. Unless a broken limb is handled carefully a simple fracture may be converted into a compound fracture; therefore, a man with a fracture should

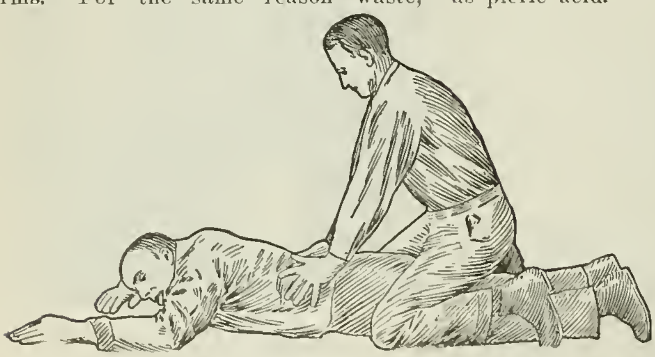

FIG. 44. SCHAEFER METHOD OF ARTIFICIAL RESPIRATION—EXPIRATION.

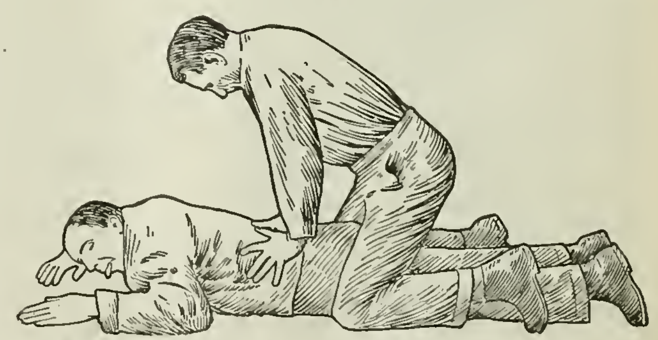

FIG. 45. SCHAEFER METHOD OF ARTIFICIAL RESPIRATION—INSPIRATION.

not be moved until a splint has been applied. A compound fracture requires a longer time for recovery than a simple fracture.

A splint is simply a light stick or piece of wood for keeping the injured part in a fixed position by means of bandages. A broken arm or leg can be placed in a straight position, and if no splint material is available, a coat may be rolled from each side toward the center over the sleeves, placed about the broken limb, and tied there. An injured arm may then be tied to the body or a broken leg to the uninjured leg.

In case of a broken back, neck, or severe crushing and internal injury a patient should not be lifted until a physician comes. Unnecessary handling is harmful, causes needless suffering, and as a physician is generally immediately available at furnace plants, first-aid in such cases is, as a rule, of questionable value. The patient may be kept flat on his back and covered with a warm blanket.

Blows on the Head or Abdomen

When a man receives a blow on the head or abdomen, first-aid is not usually possible. Avoid rough handling, loosen the clothing, do not give liquid stimulant, and call a physician at once. Don't let the patient go home alone. After receiving a severe blow on the head men have continued work, or stopped work for the day, and then suddenly became seriously ill or died. Similar developments are possible after a heavy blow on the abdomen.

Bruises and Strains

Such injuries as bruises and strains should always have the attention of a physician rather than first-aid only, for although the injury may at the outset seem very slight, it may develop into a deep-seated injury with permanent total or partial disability.

Asphxiation or Shock

To remove a victim from contact with an electric circuit, cut the current off if there is a switch handy. If not, roll or push the man's body from the circuit with a dry piece of wood or wrap your hands in a dry cloth stand on dry wood, grasp his clothing and lift his body from the wire, or place a loop of dry cloth or rope over the man's head or feet and jerk him from the wire.

In case a man has been asphyxiated or "gassed," or has received an electric shock, carry him into the open air, send for a doctor, and then proceed as follows: Feel with your finger in his mouth and throat and remove any false teeth, tobacco, etc. Lay him face downward, with one arm extended out straight beyond his head. Place his other arm under his head, and turn his face to one side, so that mouth and nose are free for breathing. Have someone draw his tongue forward. Put a folded jumper or coat under the lower part of his chest if he is thin. Straddle him on your knees, facing his head (see Fig. 44), with your knees a little below his hips; then with fingers outstretched place your hands at the lower part of his ribs with your thumbs nearly joining.

Hold your arms straight and rigid, swing forward slowly so that the weight of your body is gradually brought to bear on the subject's body; then swing back, removing the pressure, but keep your hands in place; repeat 16 to 20 times every minute. (See Figs. 44 and 45). If you have not a watch, follow the rate of your own deep breathing. Keep it up for 3 hours unless natural breathing is resumed. Keep the man warm and do not try to give liquid stimulant until he is conscious and able to talk and drink. Do not hold ammonia bottles under his nose or mouth. It is important that every foreman and every member of a safety committee in the plant should understand this method of resuscitation.

MINERAL RESOURCES OF BRITISH EMPIRE

A PAPER was read on December 11, 1916, by Dr. C. Gilbert Cullis, Professor of Economic Mineralogy in the Imperial College of Science and Technology, on "The Mineral Resources of the British Empire with regard to the Production of the Non-Ferrous Industrial Metals." The particular metals dealt with were: Copper, lead, zinc, tin, and aluminum. The object was to demonstrate the Imperial position with regard to each of these, and to show in respect of which of them the Empire was, on the one hand, self-sufficing, or, on the other, dependent upon foreign countries. In the latter case, the extent of the dependence was indicated, and methods suggested by which it might be diminished. The situation with regard to four out of the five metals was shown to be wanting in independence and scarcity, and the necessity for a full investigation of the British mine and smelter-production was insisted upon.

With regard to copper, not only were the ore-resources, as at present exploited, deficient, but the smelting facilities also were seriously inadequate for the Empire's metal requirements. The production both of ores and metal could be substantially increased by suitable organisation and administration.

Lead and zinc ores, raised in British territory, had in the past been exported on a large scale to foreign countries, notably Germany and Belgium, for metal recovery, with the result that the Empire had been placed in an anomalous position of dependence which ought never to have arisen. The shortage of zinc, in the early days of the war, and the consequent jeopardising of supplies of cartridge-brass were referred to. The mine-production of lead and zinc was more than sufficient for the Empire's requirements, but the smelting facilities were lamentably deficient, especially in the case of zinc. It was urged that all the lead and zinc concentrates of Broken Hill should in future be smelted within the Empire.

In the case of aluminum, while the actual bauxite resources of the Empire were so small that dependence had to be placed upon the French or American deposits—which were being more and more utilised in their countries of origin—large potential supplies, in the form of laterite, had a very wide distribution is the tropical colonies, but were almost untouched and untried. The systematic examination of these and other potential sources of aluminum, with a view to their utilisation, should have serious consideration.

The only metal with regard to which our position was really strong was tin. The British mine-production of tin in 1912 was 66,000 metric tons out of a world's total of 125,000, and its smelter-production 85,000. Estimating the consumption at 32,500 tons, there remained 53,000 tons for export. Now that the German market for Bolivian tin ore was closed, an opportunity had arisen of securing the whole of the Bolivian output for British smelting.

In a series of general conclusions, a plea was put forward for the elimination of wasteful methods in ore and metal recovery, for the fuller utilisation of by-products from ores, and for the adoption of large scale operations of high engineering efficiency by which capital and labour might be advantageously used. The wide-spread export of raw or partially smelted materials, produced within the Empire, to foreign countries for the recovery of the finished products was condemned, and the promotion of industries making for independence as regards essential products advocated.

The expediting of geological and mineral surveys of all British territory, and the organisation of advance investigations with the object of improving current processes, or of dscovering new ones by which geological materials hitherto unexploitable might be made productive, were urged.

The development of the mineral resources of the Empire had taken place in the past without any constructive Imperial policy: it had lacked co-ordination and control and was in need of scientific and business-like administration, and the suggestion that a Government Department of Minerals and Metals should be established to foster and safeguard mineral resources and to promote the welfare of related isdustries was strongly supported. If formed and properly conducted, such a department should do much to give security and order to what was now full of danger and disorder.

Generally speaking, each metal and alloy has a particular temperature at which it possesses maximum fluidity, this temperature usually being only slightly higher than the fusing point. Metal should always be poured as soon as ready, as it deteriorates if held too long in a molten condition.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

GEAR DRIVE PIPE THREADING MACHINE

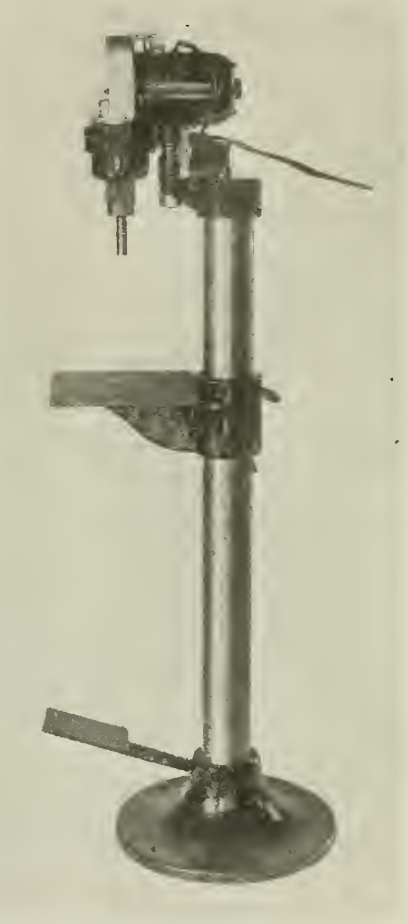
THE illustration shows a pipe threading machine having a capacity of from 2½ in. to 8 in., a feature of the machine being an all gear drive from single belt pulley, by means of which 8 changes of speed are obtained. The gear box is located at the back of the headstock and the belt pulley drives through a friction clutch controlled by the long hand lever in front of the chuck. The controlling levers for the different speeds are arranged in front of the headstock with speed plates indicating the proper position for the various sizes of pipe.

The die head is of the sliding type, with conveniently arranged handles and cam lever, and is equipped with Peerless die mechanism. The die-head can be quickly removed so as to allow very short ends or lengths of pipe to be cut off, the cutting-off tool and steady slides being on the other side of the carriage from the die-head. Renewable hardened steel facings support the pipe in the steady slides, that opposite the tool having an extra large face. The cutting-off slide is attached to one of the steady slides so that the tool is supported near the cutting edge; the reaming tool is held in a tool post on the cut-off slide.

Duplicate chucks are employed on each end of the spindle, with three independent jaws, graduated on the face for pipe sizes, the jaws on the rear clutch having special flange grippers for use in making up flange fittings. The front chuck is bolted direct to driving gear. All gears in speed box are of steel running in oil.

When equipped with motor drive, a 5 horse-power constant speed motor is used, with silent chain drive to clutch; reversing switch is fitted for cutting left hand threads. The lathe type bed is of ample strength and has a closed bottom forming drip pan, arranged at an angle to drain off compound. Ample provision is made for lubrication of all wearing parts, chain oiling bearings being provided on the spindle, and splash lubrication in gear box.

Regular equipment is complete with oil pump and connections, nine sets of dies, die cabinet and tool tray, countershaft, wrenches and extra cutting-off tool. This machine is built by John H. Hall & Sons, Brantford, Ont., weighs 7,400 lbs., and occupies a floor space 3 ft. x 9 ft.



ELECTRIC RIVETER FOR SHELL BASE PLATES.

ELECTRIC RIVETER FOR SHELL BASE PLATES

THE adaptation of electric power to the work of riveting shell base plates has been successfully accomplished by the machine shown in the accompanying engraving. The operating mechanism consists of a standard type of electric hammer which has proven highly efficient in all classes of work to which power hammers are adapted.

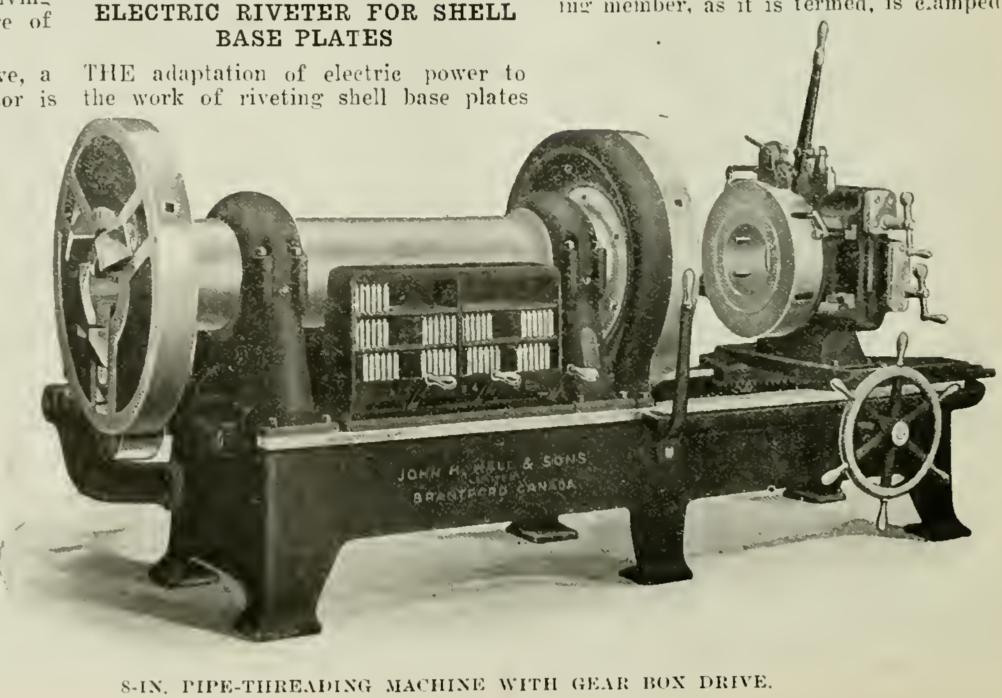
The principle member of the device is the electric motor, which is specially designed and constructed for this particular service, and is carried in a spring base pedestal, mounted on the top of the column. The striking mechanism and tool guiding device is of standard design, while an adjustable work table is carried on the turned column, the height of which is ample to allow of using any fixtures for supporting or revolving the two sizes of shells operated on, viz. 4.5 in. and 18 pdr.

Pedal control is provided for starting and stopping the hammer, which strikes 1,800 blows per min. with a force of forty pounds per blow, the net weight of the machine being 250 lbs.

This riveter as well as the complete line of regular electric hammers is marketed by R. E. T. Pringle, Ltd., Toronto.

SQUARE HOLE DRILLING DEVICE

A UNIQUE addition to existing machine shop accessory tools has been made in the production of the Radbore Head for drilling square holes. This device makes the production of square holes a commercial proposition, high quality of work, low cost of operation, and wide field of application being outstanding features of the apparatus. In drilling square holes, the flanged housing, or main guiding member, as it is termed, is clamped



8-IN. PIPE-THREADING MACHINE WITH GEAR BOX DRIVE.

to the column of a milling machine, and a drill of the required size is set in the head, after which the work is done as in ordinary drilling. See Figs. 1, 2 and 3.

The cutting of the hole is performed by a special drill made in two types, which produce either full square holes with sharp corners, or with filleted corners having a radius one-eighth the size of hole. Several sizes of drill of either

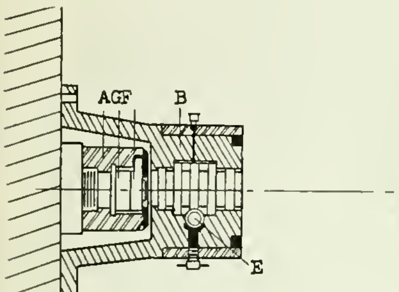


Fig. 1.

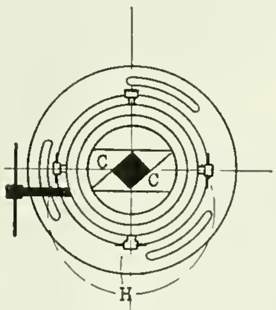

Fig. 2.

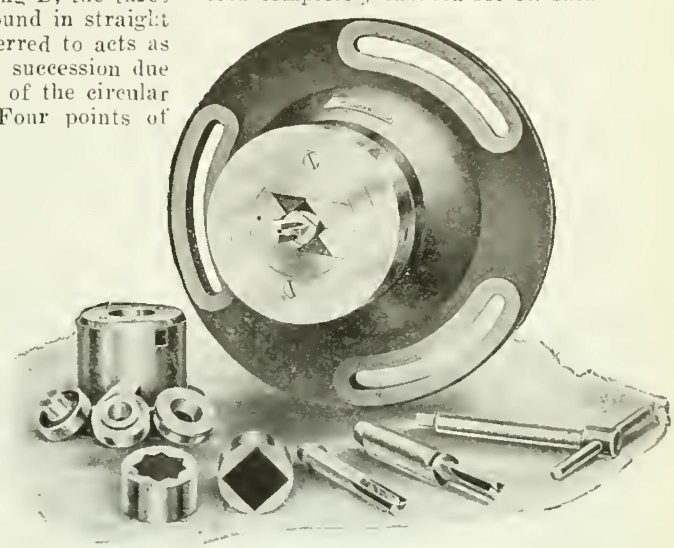

FIG. 3.

type can be used in the one head, the depth of hole possible being great enough for nearly all commercial requirements. In addition, the device will drill blind holes with a perfectly flat bottom; grinding is done on the end only, giving long life to the drill, and constant accuracy to the product.

Retctangular or oblong holes are pro-

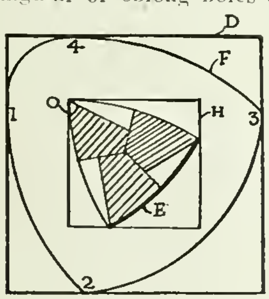

Fig. 4

duced by either feeding the stock side ways or drilling overlapping holes.

The principle on which the filleted hole is produced is shown in diagram, Fig. 5. The curved lines show the outline of the drill body which revolves in a square guide bushing the same size

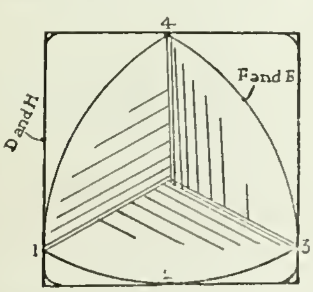

Fig. 5

as the hole. The four points of contact are present at any stage of the revolution, point 2 changing its position to the other curved lines in rotation. In drill-ink sharp corners a similar drill is used, see Fig. 4, the shank F of the drill being of such a size that the centre O of the rounded corner coincides with one of the cutting edges. As the shank revolves in the guide bushing D, the three cutting edges are led around in straight lines, while the edge referred to acts as a pivot at each corner in succession due to it being on the centre of the circular corner of the shank. Four points of support are also obtained at all times with this drill, preventing any slipping or sliding away from the fixed line of the work.

A special grinding attachment or vise can be supplied for facilitating the accurate grinding of the drills on ordinary grinding or milling machines.

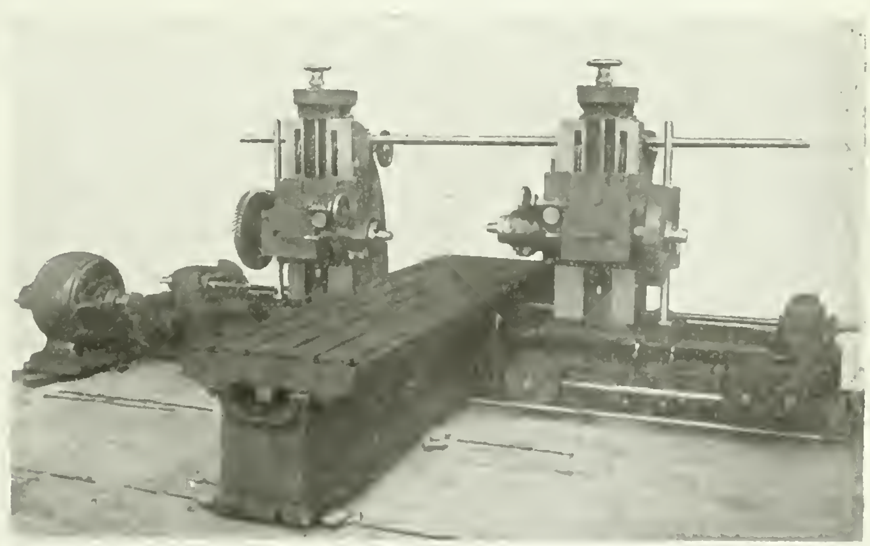
This device is being placed on the market by Aikenhead Hardware Ltd., Toronto.

SPECIAL DUPLEX MILLING MACHINE

THE machine illustrated in the accompanying engraving is interesting in that the design provides a greater degree of power control than it has hitherto been customary to provide in tools of this type. It is a recent production of the Newton Machine Tool Works, Philadelphia.

The spindles are carried in counterweighted saddles, adjustable vertically on two upright columns carried on the wings of the bed. These spindles are driven through worm and worm wheel, both completely encased for oil bath lubrication, control of the drive to each spindle being had through a clutch on the inner end of the worm wheel sleeve; the clutch lever is arranged in front of the saddle in a position convenient to the operator. Spindles are bored in the nose to accommodate a 3 in. dia. straight plug, and are arranged to drive cutters by means of $1\frac{1}{4}$ in. wide face keys: they are large enough, however, to allow of being bored No. 6 Morse taper, and having a hole through for cutter retaining bolt.

The counterweighted spindle saddles have provision for simultaneous or independent vertical adjustment with reversing vertical feed and reversing fast power traverse. They have narrow guide, alignment control bearings on the uprights, and provision for bolting rigidly at any desired height. The uprights, also, have independent and simultaneous adjustment, with reversing fast power traverse on the wings and provision for

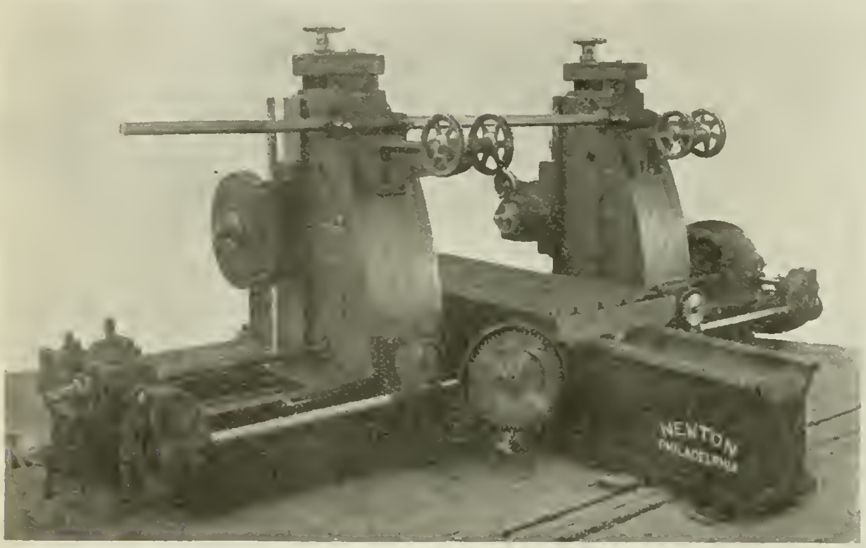


DUPLEX MILLING MACHINE WITH SPECIAL POWER CONTROL, BRACED UPRIGHTS AND SQUARE GIBBED TABLE.

bolting rigidly in any desired position. All vertical adjusting screws have bearings at each end to insure their operation under tension.

The work table has square lock bearings on the base with overlapping gibs and has angular rack and worm pinion drive, hand adjustment, 9 changes of feed through sliding gear feed box, and also has reversing rapid traverse by power.

The machine is designed to carry cutters up to 16 in. dia. when working on cast iron, is provided with suitable scales for accurately adjusting the spindle sleeve horizontally and the saddles vertically, and both spindles can rotate independently or in unison.



REAR VIEW OF DUPLEX MILLING MACHINE SHOWING ANGULAR DRIVE TO WORK TABLE.

A 20 horse-power Fort Wayne motor is employed for driving purposes, operating at 300 to 900 revs. per min., and giving spindle speeds of from 5.4 to 55.2 revs. per min.

The maximum distance between ends of spindles is 90 in., minimum 12 in.; distance, centre of spindle to table, max., 25 in., min., 2 in.; work table, 14 ft. x 42 in.; max. length, milled, 12 ft. 6 in.; dia. of spindle in worm wheel sleeve, 4 in.; dia. of spindle flange, 9 in..

TO DEVELOP RESOURCES OF THE DOMINION

EXPERIMENTS having for their object the utilization of the vast quantities of lignite to be found in Western Canada, for the production of fuel for industrial and domestic purposes, have been recommended by the Council for Scientific and Industrial Research, which has been in session at Ottawa. Investigation by the Forestry Branch of the Department of the Interior, with a view to devising methods by which the threatened destruction of the forest resources of Eastern Canada will be prevented and the forests will be made a permanent source of wealth to the Dominion, are also advocated. A proposal that industrial research bureaus, with properly equipped laboratories, be established in industrial centres in Canada, in order to assist in the solution of problems which present themselves to the manufacturers, received the support of the Council, and plans were laid for developing in Canada a body of men trained in science, and its application to industry.

Collecting Data

There was further considered at the recent meeting the various lines of work which the Council might undertake, also some forty projects which had been submitted to it. It will, within the next few weeks, issue questionaires, these being addressed to manufacturers, to technical societies, to various Government departments, and to the universities of the Dominion. They will ask information with reference to the laboratories and other agencies of research now in operation in Canada, the men now engaged in, or available for, research industries, and the bye-products produced but not at present utilized.

The Council will recommend the foundation of twenty or more scholarships or fellowships in Canadian universities and technical schools to be given to men who have completed their regular courses of study and have displayed a special aptitude for scientific research. The men to whom these scholarships or fellowships are awarded will be enabled to pursue a course of advanced work at college. Arrangements will also be made whereby students will be placed, after graduation, in the larger manufacturing establishments in Canada, to continue their training under conditions of actual commercial practice.

Body of Practical Scientists

By these measures the Council hopes to build up in the Dominion a body of practical scientists similar to that which has aided so greatly in industrial development in Germany in recent years. To furnish immediate direct assistance to manufacturing industries the Council proposes the establishment of industrial research bureaux at such centres as Toronto, Montreal and Winnipeg. These would be supplied with a complete set of technical and trade journals, would have a competent technical staff and properly equipped laboratories. In cooperation with the Provincial Government and other bodies these bureaux would be able to solve the problems which arise in their factories.

The Council has decided to examine carefully a number of the specific projects which have been submitted to it and to recommend that certain of them be taken up at once. For instance, it decided to recommend that investigations be continued with a view to utilizing the lignite to be found in Saskatchewan. Lignite in its crude state is an inferior fuel which possesses a relatively low heating power and which moreover will not stand shipment or storage. It is, therefore, of comparatively little value for domestic or manufacturing purposes. The Council, however, believes that from lignite can be produced two grades of high-class briquetted fuel, one similar to anthracite coal and the other resembling soft coal in general character, and that at the same time certain very valuable by-products may be obtained.

The Council has taken cognizance of the fact that the forests of Eastern Canada have been seriously depleted and are rapidly deteriorating in character. It has recommended that investigations be made by the Forestry Branch of the Department of the Interior with a view to ascertaining the best methods for preserving those forests and making them a permanent source of wealth to the people of the Dominion. In European countries the forests have been improved in character by the application of scientific knowledge and have been converted into assets of enormous value, yielding large revenues to the Government or their owners, and, at the same time, retaining unimpaired their capital value.

The Council has before it other important projects, but requires to examine them further before taking action with reference to them.

Purely Personal.—The commercial traveler met Sandy, the canny one, emerging from the post office.

"Ah! Sandy!" cried the traveler, "it is good to see a prosperous farmer as yourself—not forgetful of his country. You have been in the post office to purchase war bonds?"

"Nay," said Sandy easily.

"Oh! Then, perhaps you have put a little money in the savings bank that it may help the country?"

"Nay."

"Well," said the traveler as a last resort, "I suppose that you have bought a postal order to send to some poor acquaintance?"

"Nay, I've been in to fill my fountain pen."

Vol. XVII. MARCH 1, 1917 No 9.

LAST MONTH'S HAPPENINGS—THIS MONTH'S SACRIFICE AND SERVICE

THE month just closed cannot be said to have been uninteresting, lacking as it did in its twenty-eight-day span neither thrilling episode in the war activities, nor drastic legislation towards larger service and greater sacrifice in swaying the war fortunes. Germany's advised submarine propaganda against merchant vessels trading to British ports, although to a very great extent successfully combated, has nevertheless been far from barren of results, much tonnage, and not a little of it of commercially superior quality, and all of it ill-spared, has been ruthlessly sunk, together with valuable cargoes carried. The loss of life, fortunately, has been light, comparatively.

The big event of the month was, of course, the speech of David Lloyd-George, Britain's Prime Minister, in the House of Commons on February 23, to the variety detail requirement of which the nation as such was asked to submit patriotically. Neither from a superficial glance at existing conditions, nor from a deep study of the portent of events leading up to his declarations, can other than the conclusion be come to that the welfare of the people of the Motherland and the effectiveness of our arms in conjunction with those of our Allies are being menaced in most threatening degree. Vessel tonnage of commercial rating has been, all through the War, disappearing from the Register, and during the past month has been doing so at a much accelerated pace. Much of that now available—as has been the case since hostilities commenced, is a prime essential of troop, munitions and general supply transportation, and at this writing may be reckoned as more than ever of paramount importance. The decision then to put into immediate effect import restrictions of the most drastic nature, while somewhat of a shock because of their comprehensiveness, has occasioned less surprise and resentment than might have been expected, not only among Britishers themselves, but among those exporters in other countries, against whom specific enactments will exert considerable economic pressure. A list of restricted imports appears in another section of this issue.

The presence of our Prime Minister, Sir Robert Borden, in the distinguished strangers' gallery during the greater part of Lloyd-George's speech, and the reference in the latter to the conference between Britain's Colonial Secretary and Canada's Premier preceding the speech, are of more than passing interest, because of Sir Robert's statement of expressed readiness on behalf of this Dominion to sacrifice our trade share to minimize the tonnage lack emergency. That Canada is behind its Premier and is prepared to go all the way in the path he has mapped out, there is not the shadow of doubt.

Indication has already been given that Germany's submarine activity is being to a large extent combated, and in more than one sense this is true. It is a well-known fact that notwithstanding grievous losses of vessels—large and small, of valuable commercial tonnage, the percentage of ships destroyed to those entering and leaving British ports is relatively small. In this respect the measures taken to offset Germany's ruthlessness may be said to be achieving considerable degree success. Even a low percentage or gradual vessel loss is, however, neither meantime healthful nor comforting, nor will its ultimate outcome—be the war of long or short future duration—lead to anything approaching British pre-war sea-borne trade ascendency. Merchant shipbuilding, following the outbreak of war, was for many months at a standstill on Britain's river shores, so to speak, same having given place to warship construction of type, service, size and quantity that only those extremely close to headquarters administration are in a position to fully appreciate and grasp. It may, however, safely be assumed that the margin now for every fighting contingency is alike stupendous and effective. Germany's submarine effectiveness has, therefore, had to be combated in another direction—that of new freight vessel construction, and in this feature Britain may be said to be protecting herself without restriction or hindrance.

This, however, does not exhaust the possibilities of procuring additional tonnage, and its myriad supplementaries, if we rightly judge the situation. Canada's co-operative effort in munitions making has been so well and fully appreciated by the responsible authorities in the Motherland, that still greater—because of a more permanent nature, opportunities are to be made available to her. In a word, shipbuilding and marine engineering in both their basic and accessory essentials are, we understand, in process of being developed in our midst by the Imperial authorities, and on a quite comprehensive scale. As a result, it may easily be assumed that the dreaded transition period from war-time to peace-time business enterprise will be wholly negligible.

It is calculated that Canada's export trade will be affected by the import restrictions announced. On the basis of last year's exports of the affected commodities, the restrictions to be applied will cause Canadian trade diminution to amount to upwards of thirty million dollars. In a purely domestic sense the effect may be beneficial inasmuch as there will be largely conserved for the home market the commodities whose importation into Britain is now prohibited. The tendency should be towards somewhat lower prices.

Available figures for the first eleven months of 1916 show that exports of a number of the now restricted articles were valued as follows: Agricultural implements, $2,334,239; boots and shoes, $4,585,563; clocks, $1,445,313; photographic goods and motion picture films, $4,968,727; leather and tanned skins and products, $31,089,650; canned salmon, $9,380,000; wood, timber and products, $8,843,-640; typewriters, $2,952,516; books, music, maps, engravings and other printed matter, $1,138,586.

The General Market Condition and Tendency

THE possibility of the United States entering the war and the effect of such an eventuality on business in Canada is still the subject of considerable speculation in manufacturing circles. This contingency and the freight congestion are tending to unsettle the industrial situation. While business generally continues very good, particularly in the steel trade, production is being restricted owing to poor shipping facilities; in consequence deliveries of manufactured products are falling behind. Manufacturers are still suffering from a shortage of fuel and raw materials, while the scarcity of suitable labor is also causing much inconvenience. Assisted by improved weather conditions the railways have been able to move a larger volume of freight recently, thus relieving the congestion to some extent. It will, however, be some time before conditions are normal. The iron and steel market continues very strong and indications point to higher prices on all steel products. The principal advances this week include boiler and structural rivets, wire products, including wire nails, pressed steel spikes, and cut nails. Export demand for steel products continues heavy, but production is still being restricted, owing to the shortage of coke and pig-iron. The ingot metal markets are strong, reflecting the expectation that the United States will declare war on Germany, in which event an increase in demand for war metals would result. Copper, lead and spelter have advanced, due principally to a scarcity of spot metal in the East, resulting from the railway embargoes. The scrap metal market is strong and prices have been well maintained. The machine tool market is quiet and demand light.

Montreal, Que., Feb. 26.—The industrial situation is suffering from a lack of all classes of commodities, due to lack of transportation facilities. The wave of freight congestion has passed from the Atlantic seaboard back to the Middle West, thus reducing railroad communication to a minimum. The effects have been all too apparent in lack of fuel, while materials for manufacturing have been so scarce that many plants have had to close down temporarily. A spell of mild weather afforded some slight relief, but only a change in basic conditions can ameliorate to any considerable degree the present unfortunate conditions.

Pig Iron

The outlook for a stronger market in pig iron seems apparent owing to the curtailment in production that has resulted from the lack of raw materials. Prices on American pig are already advancing, and prospects of early relief are not encouraging. Developments now in progress may still further affect the situation.

Steel

The paralyzed condition of trade generally is probably more emphasized in the steel industry than in any other, owing to the dependency that at present is placed upon this commodity. Instead of improvement, the trade is anticipating a still more serious condition, and transportation facilities are daily becoming more demoralized, rapidly approaching a stage where a crisis appears imminent. The non-delivery of raw materials is placing the mills and furnaces in a very serious position, and shutdowns are reported daily. This results in a material decrease in production, which must naturally be transmitted to the other lines of activity, affecting not only the output of manufacturing plants, but creating a situation that may have a serious effect on early future conditions. Steel dealers here report a situation that is rapidly becoming serious, and they look forward to an early revision of prices that will reflect the actual condition of the market. While no local price changes have been put into effect, the early future is expected to show some interesting developments in an upward direction. The production of billets and sheet bars has been curtailed owing to the non-delivery of raw material, and higher prices are not unlikely. Pittsburg quotations on rolling billets show an advance of $2 per ton. The demand for ferro-alloys has quieted down, but prices are very firm. The situation in plates continues tense, as the mills are unable to supply the abnormal requirements of shipbuilders and general manufacturers. The sheet situation is unchanged and very firm, with early future prices depending on current developments. Wire and wire products retain an even tone, but owing to the high cost of wire rods, an early advance on wire products is not unlikely. Activity in bars is better, the demand having improved. Inquiries for wrought iron pipe and boiler tubes are good, and further advances may be looked for.

Metals

The general metal situation is without change, being still affected by the freight situation and the continued political uncertainty. Metals coming from the West are greatly delayed, and the spot supply is scarce. With the exception of tin, all metals are in a strong position. Copper is firm, but inactive. The knowledge that tin is easier would indicate that the marine risk has been lessened. Spelter is quiet, but prompt metal is scarce. Lead is very strong on the outside market. Delayed delivery of antimony has created a stronger market.

Copper.—The quiet state of the market gives little opportunity to get a definite line on the situation. Little activity is taking place, and the trade is apparently awaiting developments on which their future operations may be based. The London market is a little easier, while quotations in New York are higher; lake is quoted at 36c, with electrolytic at 37c, these prices being 1c and ½c higher than last week. Local conditions remain firm and unchanged, with quotations steady at 40c for lake and electrolytic, and 39c for castings.

Tin.—Conditions exist throughout the market that tend to irregularity in price quotations, as each transaction is considered on its own merits. The market on the whole is lower than last week, both in London and New York; the latter being ⅝c easier than a week ago, the current price being 49⅜c per lb. Dealers here report an easier market, but prices are unchanged at 51c per lb.

Spelter.—There is little activity in spelter, and buying and selling are almost at a standstill. A stronger tendency is noted, due to the scarcity of spot metal, caused by freight congestion. New York is quoting 10⅞c, this being an advance on last week of ⅝c per lb. Spelter remains firm locally at 15c per lb.

Lead.—While prices are higher in the open market, all quotations are of a nominal nature. The trust continues to quote 8½c, but independents are asking as high as 10¾c. An undertone of strength is noted in local circles, but the nominal quotation is still 12½c per lb.

Antimony.—This metal is again advancing owing to the apparent scarcity arising out of the delay in shipments now en route from the East. The situation here is strong on an advance of 4c, the quotation being 34c per lb.

Machine Tools and Supplies

While the present activity is not abnormal, the trade is experiencing great inconvenience owing to difficulty in obtaining supplies and inability to ship their product with any degree of definite delivery. Greater interest is being shown by shell manufacturers regarding machine equipment, due to the prospect of further renewals of munition contracts. While no definite information on this point is available, it is expected that additional orders will be placed in the near future for increased quantities of shells, involving still further additions to plant. Prices continue to hold firm, and prospects indicate still higher prices. The situation in the States is still subject to political influences, and manufacturers are cautious about closing contracts for future business.

Scrap

The freight situation is reflected in the stronger position of all scraps, and prices have an upward tendency, which may be still further pronounced unless relief is given to the present railroad congestion. Dealers report good business, but the volume is light. From one half to one cent has been added to New York quotations. The local changes are confined to copper and brass scrap and machine composition. Coppers have advanced 1c on the week, the current price being 23c and 27c per lb. Machine compositions are now 22c, and brass clippings 18c, these showing an advance of ½c per lb.

Toronto, Ont., Feb. 27.—The industrial situation continues to be affected by the shortage of fuel and raw materials. Although the movement of cars has been heavier, assisted materially by the milder weather, there still remains a considerable volume of freight to move before the congestion is relieved sufficiently to bring about reasonably normal conditions. The extensive embargo which has been placed on imports into Great Britain by the British Government will affect Canadian export to some extent on a number of lines. As the bulk of the export trade consists at present of foodstuffs and war materials, the effect will not be serious. The exportation of most of the manufactured goods regarded by the British Government as non-essentials and included in the prohibited list has steadily declined during the past two years.

Steel

Although the railways have been able to relieve the congestion to some extent aided by more favorable weather, the situation as it affects the steel trade in this section of the country cannot be said to have improved materially. The amount of coke and pig iron received at the furnaces has been quite inadequate and it has not been possible to extend operations. Output at the furnaces has therefore not increased, and steel production as a result has been curtailed. It is reasonable to suppose however that during the next three or four weeks, provided the weather is not too severe, there will be a considerable improvement effected and result in more favorable conditions at the mills and foundries. The export demand for steel continues insistent, the mills having already booked considerable business for 1918. The steel market is thus very strong and prices are advancing. Pressed steel spikes have advanced 50c and are now quoted at $4.60 per 100 lbs. It is understood that the Dominion Government has an enquiry out for 6000 kegs for delivery from June 15 to Sept. 1, this year. Boiler and structural rivets are higher being now quoted at $6.35 and $6.25 per 100 lbs. respectively. Cut nails have advanced 20c to $4.70. There has been a sharp advance recently in wire products, including wire nails, as a result of the continued high price and scarcity of wire rods. A sale, it is reported, of soft Bessemer or open hearth wire rods was made recently to Canadian interests on a basis of $80 f.o.b. mill, Pittsburgh. Smooth steel wire No. 0-9 gauge is now quoted locally $5.25 base, and wire nails $4.95 per keg base. The demand for plates continues very heavy and prices are very firm with a decided upward tendency. Higer prices on boiler tubes are also looked for in the near future owing to the heavy demand and sold-up condition of the mills.

The sheets mills continue to operate at reduced capacity owing to the shortage of sheet bars and lack of fuel. On this account many mills are working part time or are closed down altogether. Deliveries are consequently falling behind and prices are tending upwards. It is fully expected that there will also be an advance on galvanized sheets shortly.

The shortage of fuel continues to be the principal feature in the steel trade in the United States. Although there has been quite recently an improvement in the railway situation, there is no real measure of relief to the mills and the output of semi-finished and finished steel this month is bound to show a heavy falling off as compared with January. The congestion at the seaboard is as acute as ever and railway embargoes are operative in all directions. Prices on all steel products continue very firm and advances have been made on billets and sheet bars. Forging billets are now quoted at $90, open hearth billets $65, and wire rods $80 per ton, Pittsburgh. Tank plates are up to 5c and steel hoops to 3.75c Pittsburgh.

Pig Iron

The pig iron market continues very strong with very little improvement in freight conditions. The difficulty being experienced in getting coke and other raw materials, combined with a shortage of labor is checking furnace production. A large number of furnaces in the

States are banked owing to the shortage of coke, while this material is also increasing in cost. The situation in Canada is still acute with no immediate relief in sight.

Scrap

The market is strong and active with good demand particularly for steel scrap. No price changes have been made during the week, but advances on some lines of old material are looked for in the near future. Low phosphorous steel scrap is in good demand and prices are high owing to the high cost of low phosphorous pig iron. There is a moderate demand for steel borings and turnings at prices last quoted. Supplies of this material are in good volume. Prices of old copper and brass are firm at unchanged quotations.

Machine Tools

There is practically no change in the situation. The market is inclined to be dull as demand is comparatively light at the present time. Fuse manufacturers have been in the market for single tools to balance up equipment to increase production. There is also a fair demand for tool-makers' equipments. The embargo which the British Government has placed on a large variety of imports may affect the trade in Canada, unless the tools are urgently required for munitions plants and cannot be obtained in Great Britain.

Supplies

Business continues active and prices on practically all lines of machine shop supplies are very firm. There have not been many changes of importance announced during the week, but indications point to higher values all round. Lead wool is up 1c, and is now 15c per lb. Some new discounts on twist drills and reamers will be found in the selected market quotations.

Metals

The possibility of the United States entering the war is the principal feature in the metal markets. Such a development would doubtless result in an increased demand for metals for war purposes, and consequently prices would advance. This expectation is giving a strong tone to the markets and prices are very firm, although nominal for most of the metals. Copper, spelter and lead are higher, prices of other metals being unchanged. Business locally continues very good, and there is an optimistic feling in the trade.

Copper.—The market continues strong and quotations are nominal as there is not sufficient business to establish prices, there being very little copper actually offered for sale. Copper has advanced 1c locally and is now quoted at 39c per pound.

Tin.—The situation is very strong and prices have an upward tendency. The possibility of cargoes of tin being lost through submarine activities is affecting the situation and will tend to keep prices firm. Local quotations unchanged and nominal at 56c per pound.

Spelter.—The higher cost of zinc ore is reflected in an advance in spelter, producers having marked up quotations. Spelter has advanced ½c, and is quoted at 14c per pound.

Lead.—The continued scarcity of lead in the East on account of the freight situation has resulted in a further advance in price as fixed by independents who are quoting 10.25c to 10.75c New York, although the "Trust," price is unchanged at 8.50c New York. Lead has advanced ½c locally, and is now quoted at 12½c per pound.

Antimony.—The market is quiet, but firm. A scarcity of spot antimony has developed which is tending to advance prices. The freight congestion is affecting the situation. Local quotation unchanged at 35c per pound.

Aluminum.—Quotations are firm, spot metal being at a premium in the East on account of the railway situation. Local quotation firm and unchanged at 68c per pound.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

BARRED FROM IMPORT BY GREAT BRITAIN

THE Official Gazette gives a list of articles, the importation of which is prohibited into Great Britain as from Feb. 24, 1917. The list includes agricultural machinery, boots and shoes of leather, raw fruits except lemons and oranges, hides, leather, gloves, glass manufactures, linen and yarns and manufactures thereof, canned lobsters and salmon, manufactured silk and skins, furs, food articles containing sugar, except condensed milk; tomatoes, typewriters, wine of all kinds, wood and timber, aerated, mineral and table waters; antimony ware, apparel not water-proofed, works of art, baskets and bamboo, basketware, books, and other printed matter, including posters and daily and weekly and other periodicals exceeding 16 pages; materials for the manufacture of leather boots and shoes, brandy, clocks, and parts thereof, cloisonne ware, raw cocoa and preparations thereof, coffee, cotton hosiery, cotton lace and articles thereof, curios, diatomine and infusorial earth, embroidery and needlework, fancy and ornamental feathers and down, fire extinguishers, flowers, artificial and fresh; hats and bonnets, incandescent gas mantles, raw jute mats and matting, mops, painters' colors and pigments, perfumery, photographic apparatus, pictures, prints, engravings, photographs and maps, plated and gilt wares, live quails, quebracho, hemlock, oak and mangrove extracts, rum, Soya beans, stereoscopes, straw envelopes for bottles and straw plaiting, tea. Both wet and dry hides and dressed and undressed leather are included. Silky yarns are exempted. The prohibitions do not apply to goods imported under license given by the Board of Trade.

TORONTO HARBOR DEVELOPMENT PROGRAMME

OVER $3,000,000 may be spent on harbor development work this year by the Toronto Harbor Commission in addition to $1,000,000 which the Dominion Government has placed in the estimates for 1917. Detailed plans are now in process of being worked out by the engineering staff of the Commission, and will shortly be submitted to the city by the Commissioners for approval. There is, however, just a possibility that very little work can be undertaken this year, owing to the scarcity of timber, due to export and labor shortage. All timber used this year will have to be brought from British Columbia and present prices are such that the cost may be considered prohibitive. It was originally intended that the new harbor would be completed some time during the year 1921. This is no longer considered possible.

This Year's Plans

Plans for this year contemplate a beginning on the cribbing and piling for the docks in the central district between John and Cherry streets. This work will have to be undertaken in piecemeal fashion so that present dockage facilities will not be interrupted. This year the sinking of piles will, it is expected, only be proceeded with as far east as Spadina avenue. There will also be work along this line, beginning at the old Queen's wharf.

Further reclamation work will be undertaken in Ashbridge's Bay, the industrial district, providing several hundred additional acres for new industries. The Government will be asked to proceed with the retaining wall opposite the Exhibition Grounds and the Harbor Commission will then undertake the work of pumping sand over and filling in.

About $400,000 is to be spent on reclamation work at Centre Island and Hanlan's Point. A block of about fifty acres is to be reclaimed at Centre Island on the immediate west side. Twenty-five acres is to be reclaimed at Hanlan's Point north of the wharf and baseball park. Both of these sections were commenced last year and will, if possible, be completed during 1917.

Estimates for 1917

The estimates of the Harbor Commission show the following contemplated expenditures for 1917:

Construction and acquiring of property, and its equipment, $2,997,763.21; stores and rotary, $41,580; insurance $23,346; engineering and management,

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—H. R. Poussette, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—Acting Trade Commissioner, Lonja del Commercio, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—G. B. Johnson, P. O. Box 109, Yokohoma. Cable address, Canadian.

HOLLAND—Acting Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrivskaya. Ploshch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 27-28 Pearl Building, East Paradise, Leeds. Cable address, Canadian. F. A. C. Bickerdike, Canada Chambers, 36 Spring Gardens, Manchester. Cable address, Cantracom. J. T. Lithgow, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.

SPECIAL TRADE COMMISSIONER—LUMBER

H. R. McMillan, visiting Europe, Africa, Australasia and the Orient.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin, Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum Grubbeged No. 4, Christiania, Norway. Cable address, Sontums.

CANADIAN HIGH COMMISSIONER'S OFFICE

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

$180,290; revenue producing service, $32,120; upkeep of property and equipment, $11,000. The revenue and proceeds of the Harbor Commission from 1912 to 1916, inclusive, total $6,672,466.78, and the expenditure for the same period was $6,311,775.81, leaving a surplus of $340,690.97. The estimated revenue for 1917 is placed at $160,000.

This year's estimates provide for $60,000 for freeholds in Eastern avenue properties, and $20,000 for the Boulevard-Cliff Road, and $2,000 for a long-time lease hold of the Eastern sandbar. The sum of $150,000 is provided for a new office building. Bath houses, including public protection, are to cost $5,000.

Improve Industrial Area

For roadways there are the following expenditures: Boulevard drive, Cliff Road, $15,250; Boulevard drive, Wilson to the Humber, $87,984; 150 foot roadway, Cherry street to the Don, $10,000, and in the industrial district, $10,000. Sidewalks and curbs call for the following expenditures: Boulevard--Cliff Road to the Humber, $55,000; 150-foot roadway, Cherry street to the Don, $5,000, and in the industrial district, $25,000.

The Cherry street bascule bridge is to cost $50,000, and the Don railway bridge $43,280. Piers, docks, and quays call for $750,369.64, being four sections of the harbor head walls, two of which are under contract, Just where these will be located has not yet been made public. In addition to the above there is an appropriation of $65,000 for the Humber bastion wall.

Underground service appropriations provide for storm sewer overflow extensions at Keele street, Garrison Creek, and Bathurst streets, Booth, Logan and Carlaw avenues, and for a storm sewer in the industrial district, the total estimated cost being $281,591.10. Railways, tramway embankments and tracks will require $60,000.

$708,333 for Dredging

Estimates for non-structural improvements include $658,333 for dredging under the Canadian Stewart Co. contract, and $50,000 for the Harbor Commissioner's plant. An even $100,000 is provided for general retention work and $7,000 is due to be spent on surfacing in the industrial district, in the vicinity of the Sunnyside pavilion and at the Parkdale Canoe Club. The sum of $15,200 is set aside for razing structures and removing obstructions.

Payment of debts and payment to sinking fund will take $296,000. Initial construction of pile drivers, scows and betterments to dredges, derricks, pile drivers, and to tug, will, it is estimated, require $30,000. The sum of $25,000 is in the estimates for a marine railway and $2,350 for power tools. There is also $15,000 for the Sunnyside pavilion and $1,500 for dockyard fences. Plant operation will require $18,080, and stores, comprising construction, stationery, motor service and commissariat, $20,900.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Montreal, Que.—It is understood that the G.T.R. is in the market for twenty-five locomotives.

Ladysmith, B.C.—It is proposed to start operations at the smelter here, also to extend the plant.

Kitchener, Ont.—Fire did $475 worth of damage to the Gies Foundry, on Water street, on Feb. 23.

Sherbrooke, Que.—Mackinnon, Holmes & Co. will rebuild their plant which was recently destroyed by fire.

Port Hope, Ont.—The Brandon Machine Co., is installing machinery at the new plant here. The tool room is already in operation.

Oil Springs, Ont.—The Canadian Oil Products Co., will replace its oil-pumping machinery recently destroyed by fire with a loss of $5,000.

Chignecto, N.S.—The Maritime Coal, Railway & Power Co., proposes to purchase electric pumps, motors, etc., for to plant. R. J. Bell is general manager.

Fredericton, N.B.—Fraser Ltd., of this town are building a bleached sulphite pulp mill at Edmunston, N.B., which will have a capacity of about 100 to 125 tons per day.

Three Rivers, Que.—The Quebec Steel Foundries, Ltd., are building a plant here. Messrs. Massicotte and Gagnon, of Ste. Anne de la Perade, are interested in the company.

Eburne, B.C.—The British Pacific Iron & Steel Co. has placed an order for open-hearth furnaces for the steel plant they will erect on the Fraser River, near Eburne. A site of 10 acres has been secured.

Vancouver, B.C.—The Pacific Mills, Ltd., Ocean Falls, B.C., is erecting a pulp and paper mill of 100 tons a day capacity to be ready for operation by April. It is owned by the Crown Willamette Paper Co. of Vancouver.

Guelph, Ont.—In a few weeks the International Malleable Iron Co., expects to proceed with the erection of a large addition to their plant. The new building will be 216 feet long, one storey high. Tenders are now being received for the construction.

Trenton, Ont.—The British Chemical Co. have extended their plans and have purchased a large block of land in Patricia Park. Messrs. Fraser, Brace & Co., of Montreal, have a contract to erect between thirty and forty buildings on this property for a smokeless powder plant.

Windsor, Ont.—Preparations for the development of the quarries at Amherstburg by the Solvay Process Co. are already under way. Gordon S. Rutherford, newly appointed general resident manager of the company, has already taken charge and has planned his campaign.

Port Arthur, Ont.—Arrangements are being made by the Grain Growers' Grain Co., which recently erected a hospital elevator here with a storage capacity of 200,000 bushels, for the doubling of that storage capacity. This will necessitate the construction of nine or ten new tanks. Work is to be started as soon as possible.

Montreal, Que.—The Montreal Locomotive Co. have taken out permits for the erection of four distinct additions to their plant. All of these buildings will be located on Notre Dame east, and together will cost in the vicinity of $6,300. There will be one 45 x 290 to cost $1,400, a second 84 x 32 to cost $1,400, a third 84 x 32 to cost $1,300, and a fourth 100 x 200 to cost $1,800.

Campbellford, Ont.—Work has begun on the rebuilding of the Dickson Bridge Co.'s plant here, which was burned some weeks ago. It is stated that the National Mfg. Co., of Ottawa and Brockville, have purchased a controlling interest, but that the firm will still be known as the Dickson Bridge Works Co. Men are now at work reconstructing the buildings. A. H. McKeel has charge of the work.

Toronto, Ont.—The Local Board of Health has granted to W. Harris & Co., Danforth avenue, a permit to establish in the Ashbridge's Bay harbor industrial area 175 feet east of the diversion of the River Don, a plant for the manufacture of gelatine, glues and renderings. The initial unit of the plant will cost about $50,000, but extensions will be made at a later date.

Montreal ,Que.—The Thomas Davidson Mfg. Co., have taken out a permit to erect a plant near the Lachine Canal, between the Canada Car and Dominion Mahogany factories, to cost in the vicinity of $25,000. This plant will have dimensions of 200 x 50 and will be used for the manufacture of munitions while the war lasts and then will be used in the manufacture of the company's ordinary product.

Hull, Que.—The Hull Iron & Steel Foundries are making considerable extensions to their plant, including a machine shop extension, 40 ft by 90 ft.; office building to cost $20,000; two 20-ton, open-hearth furnaces, approximate cost $50,000. New equipment to be installed will consist of one 30-ton overhead traveling crane for the main foundry; one 10-ton crane, 40 ft. span, with 800 ft. runway, into the yard. Three heavy duty engine lathes will also be required.

Cornwall, Ont. — The Town' Council who for some time past have been endeavoring to obtain power, believe that 5000 additional horse power will be supplied by the Cedar Rapids Transmission Co. The company's engineers are now at work on plans for a transmission house and plant to be erected near here as soon as it is possible to get the project under way. It is expected that a unit of 3,000 horse power will be installed. The plant will be designed and built so as to permit additional units being quickly installed.

MUNICIPAL

Sudbury, Ont. — The Town Council proposes to spend $7,000 on extensions to its power plant. W. J. Ross is clerk.

Winnipeg, Man.—The City Council are considering enlarging the Point du Bois power plant to 100,000 h.p., at a cost of $150,000.

Englehart, Ont.—The Northern Ontario Light and Power Co. have now completed their transmission line to Kirkland Lake, a distance of approximately sixty-five miles.

Merrickville, Ont.—A by-law to grant a bonus of $30,000 to the Rideau Power Co., was carried by a large majority by the ratepayers on Feb. 26, only five votes being cast against it.

St. Vital, Man.—The Rural Municipality of St. Vital have for sale approximately 7,000 feet of 6 in. cast iron pipe, specials hydrants, valves and boxes. J. Desourdis is sec-treasurer.

Chatham, Ont.—The City Council has endorsed the proposition of the Public Utilities Commission whereby it is proposed that the city purchase the electrical business of the Chatham Gas Co. for $115,000, thus extending the present hydro system and removing all competition.

Montreal, Que.—The Board of Control may sanction an increase in cost of the Lasalle bridge. T. O'Sullivan was awarded the contract for the work at $209,000 but claims that $30,000 more than that sum would be required to cover the increased cost of materials.

Chatham, Ont.—The City Council has endorsed the proposition of the Public Utilities Commission whereby it is proposed that the city purchase the electrical business of the Chatham Gas Co. for $115,000, thus extending the present hydro system and eliminating all competition. The matter will now be referred to the Ontario Municipal and Railway Board without a vote of the people.

ILLINOIS TOOL WORKS
CHICAGO
A Helpful, Technical Service for Gear Makers
THIS Company maintains a completely equipped department for the designing and execution of SPECIAL hobs and cutters: a broad, constructive work which our engineers have been developing since the founding of this business. It has become an important, permanent feature of our service, now at the disposal of all who are confronted with perplexing tool problems, especially hobbing.
We would welcome the opportunity to demonstrate how you could use this service to advantage, and cordially invite you to confer with our Engineering Department in person or by letter.

GENERAL

Stratford, Ont.—The McLeod Milling Co. are in the market for electrical equipment.

London, Ont.—The Quaker Oats Co., of Peterboro, propose to erect a $100,000 addition to the local plant, which they recently acquired.

Winnipeg, Man.—Fire on February 22 in the premises of the Great West Saddlery Co. here caused damage to stock and building estimated at $40,000.

Belleville, Ont.—The Maple Leaf Rubber Co., are building a factory here for manufacturing tires and rubber goods. The buildings will be completed early this summer.

Ste. Rese, Que.—Damage exceeding $15,000 was done here on February 17 by a fire which partially destroyed the saw mill of Cyr & Freres.

Windsor, Ont.—The Canadian Oil Co., proposes to erect a factory for the manufacture of oils, paints, etc. A by-law will be prepared and a vote taken on the question of the city selling a site on Howard Ave. to the company.

Montreal, Que.—A factory of 190 x 100 is now being completed for the Thompson & Norris Co. of Canada in the vicinity of Masson street and the Canadian Pacific tracks. This company formerly sold goods, corrugated paper products, in Canada through their factories in Brooklyn, Boston, and even London, England.

Westport, Ont.—The Dominion Cutlery Co. of Montreal, have taken over a plant to manufacture cutlery. The property is situated at Westport, Ont., and consists of two buildings, three storeys each, containing 22,000 square feet of floor space, a machine shop, plating plant and water power equipment. Additional machinery is now being installed, and the plant is now in operation. The officers of the company state that a general line of cutlery such as pocket knives, scissors, razors will be turned out for which a large number of orders are on hand.

TENDERS

Toronto, Ont.—Tenders, addressed to the chairman of the Toronto Electric Commissioners, will be received until March 28, for synchronous condensers Specifications may be obtained at the office of the purchasing agent, 15 Wilton Avenue, Toronto.

Toronto, Ont.—Tenders will be received up to March 7, for the supply of road oils, asphalts, tars, and four oil wagons for the York Highway Commission. Specifications may be secured from E. A. James, township engineer, 57 Adelaide street, Toronto.

Victoria, B.C.—Tenders will be received up to March 5, for the following electrical supplies: — 5,000 carbons, solid; 5,000 carbons, cored; 3,000 nitrogen lamps; tungsten lamps. Specifications may be obtained from W. Galt, city purchasing agent.

Winnipeg, Man.—Tenders will be received up to March 15, by R. D. Waugh, Chairman of Commissioners, Greater Winnipeg Water District, for the supply of approximately 12,500 feet of 48-in. and 1,300 feet of 60-in. cast iron pipes, together with specials and gate valves. Specifications on application to the offices of the District, 501 Tribune Building, Winnipeg.

Hamilton, Ont.—Tenders will be received by the Board of Control up to March 5, for the supply of ordinary and special castings, iron pipe, hydrants, valves, extension boxes, lead pipe, pig lead, rubber hose, rubber boots, road oil, lubricating oil, flux, fuel oil, coal oil, gasoline, brass work, including ordinary and special brass castings for water department, hardware, etc. Specifications may be obtained at the office of E. R. Gray, city engineer.

Quebec, Que.—Tenders will be received at the Quebec Harbor Commissioners' offices up to March 12, for the construction and delivery, in complete working order, in accordance with the exhibited plans and specifications, of a grain storage annex (of about 1,000,000 bushels capacity), to the commissioners' present concrete elevator No. 2. Plans and specifications of the proposed work may be seen, and forms of tender obtained, at the Harbor Engineer's office, Quebec.

REFRIGERATION

Chatham, Ont.—By a vote of 846 to 105, the ratepayers on February 20 sustained a by-law to grant a site of eleven acres, valued at $5,500, to Libby, McNeil & Libby Co. of Canada, for the establishment of a large packing and pickling plant. The company is a Canadian branch of the Chicago packing house of the same name. They will expend, to begin with, more than $100,000 on a plant to care for business in Canada and British possessions.

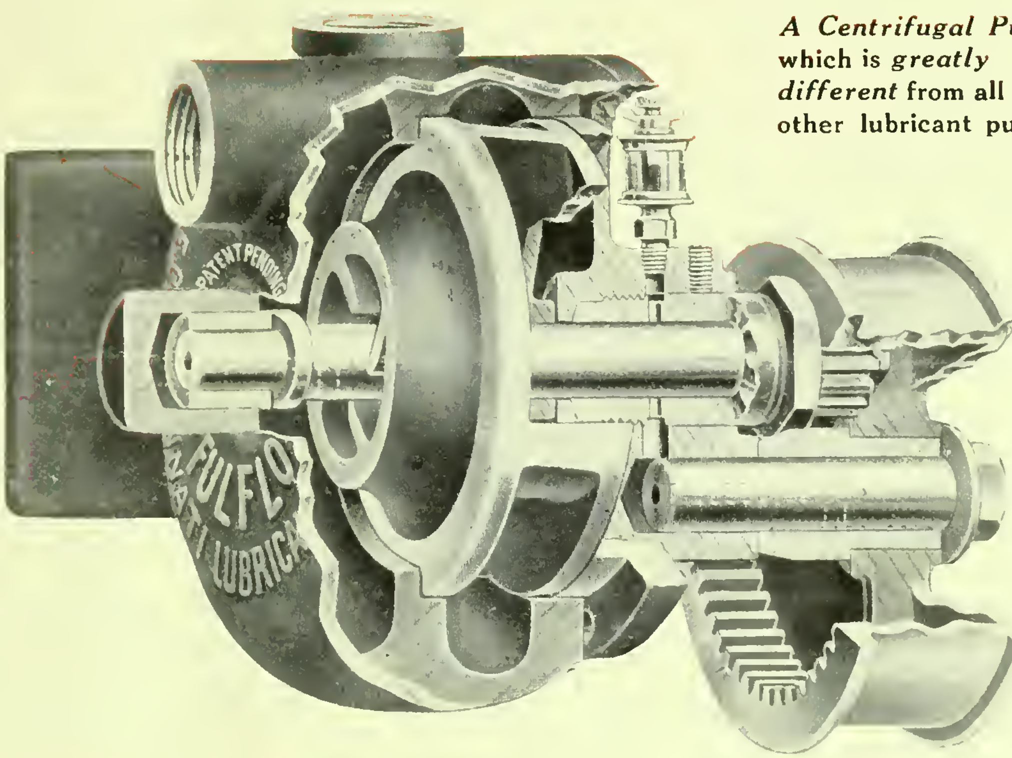
INCORPORATIONS

The Mount Elgin Milk Products Ltd., has ben incorporated at Toronto to manufacture butter, cheese and milk products of all kinds at Mount Elgin, Ont. The provisional directors are John A. Morrison, James W. Stoakley and Emerson Moulton all of Dereham Township, Ont.

McCallum-MacLaren Ltd., has been incorporated at Toronto with a capital of $40,000 to manufacture sash, doors, vehicles and implements etc. with head office at Toronto. The provisional directors are B. George McCallum, Harvey L. McCallum and Charles D. MacLaren all of Toronto.

Metal Specialties Ltd., has been incorporated at Toronto with a capital of $40,000, to manufacture metal products of all kinds, aeroplaues etc., and to carry on a general engineering business with head office at Toronto. The incorporators are Edwin G. Long, Harry S. Sprague and Joseph E. Belfry all of Toronto.

The Lubricant Pump You've Looked For



A Centrifugal Pump which is *greatly different* from all other lubricant pumps

Fulflo Lubricant Pump

"The Pump Efficient"

1 ***GREATEST CAPACITY.*** 50% more volume than any other pump its size. 1 to 20 gallons per minute according to speed.

2 ***CANNOT LOSE ITS PRIME.*** Water has to run uphill before the Fulflo can lose its prime. All other pumps depend on valves to hold their prime.

3 ***LONGEST LIFE.*** There is but one pumping part—the impellor—and it touches nothing but the liquid, therefore retains its pumping efficiency indefinitely.

4 ***WON'T CLOG.*** Anything that can get in will go right through without injury to the pump. No passage smaller than intake which is ¾ inch.

Send for a copy of "Scientific Lubrication of Cutting Tools." It is FREE to all mechanical executives.

The Cincinnati Lubricant Pump Company

Why do you suppose such people as these are replacing the gear-type lubricant pumps which came with their machines with FULFLOS-- *the new centrifugal type* lubricant pumps?

The Dayton Engineering Laboratories Co

Dayton Ohio May 20 1916

The Cincinnati Lubricant Pump Co.
126 Opera Place
Cincinnati, Ohio

Gentlemen:

We are enclosing herewith copy of a letter to the ———— Co. requesting them to equip ten of our machines on order with your pumps.

Yours very truly,

F. L. Walter

THE DAYTON ENGINEERING LABORATORIES CO

D*EAR

Nothing but Fulflos will be used here.

E. C. ATKINS & COMPANY
SILVER STEEL SAWS

The Cincinnati Lubricant Pump Company
Cincinnati, Ohio

Gentlemen:

We are pleased to state that we have in operation at the present time a number of your Fulflo pumps and are having excellent service from them. We were a little skeptical about placing the first order sometime ago but after testing the first pump out thoroughly we were very much pleased with its performance and gave you two additional orders on the strength of the results we obtained. We have had no trouble at all so far in the operation of the pumps and are frank to say that you certainly have a very efficient pump for machine shop practice.

Yours truly,
E. C. ATKINS & COMPANY
Wm. A. Atkins
Supt.

Troubles Overcome

Orders More Fulflos

They Insisted on Getting Fulflos

COPY

The ———— Co
———— Ill.

Gentlemen:-

Referring to our order 8-5C622 for ten No.—— machines, we would like to know if it would be possible for you to furnish a "Fulflo" Lubricant Pump instead of the geared pump which you are furnishing at the present time. We have found this pump to be much better than the geared pump and we are at the present time replacing many of our geared pumps with this style of pump.

We are enclosing a circular giving a description of this pump and are also sending a copy of this letter to the Cincinnati Lubricant Pump Co of 126 Opera Place, Cincinnati, Ohio.

Thanking you in advance for anything you can do for us in this matter we are

Yours very truly,

FL* EAH THE DAYTON ENGINEERING LABORATORIES CO

The Cushman Chuck Company
CUSHMAN CHUCKS
Hartford Conn.

Gentlemen:

We are using your "Fulflo" Pump with great success and we consider them 100% better than the best type of Geared Pump which we have used heretofore. All our future orders will be for the "Fulflo" Pump and we recommend them to anyone who wishes to use a pump that will give them the least amount of trouble.

Yours very truly,
THE CUSHMAN CHUCK COMPANY
A. P. Sloan
Vice-President.

ARS/B

Fulflo Found to be the Best

Here are the names of several concerns in America which have in use from 100 to 600 Fulflo Lubricant Pumps.

Buick Motor Company	Flint, Mich.
P. Lyall & Sons Construction Co.	Montreal, Can.
Northway Motor Company	Detroit, Mich.
Wagner Electric Company	St. Louis, Mo.
Dayton Engineering Laboratories	Dayton, Ohio
Remington U.M.C. Company	Bridgeport, Conn.
Richmond Radiator Company	Philadelphia, Pa.
Pennsylvania Railway Company	Pittsburgh, Pa.
American Clay Machinery Company	Bucyrus, O.
Russel Motor Car Company	Toronto, Can.

and there are hundreds of others.

Send for a copy of "Scientific Lubrication of Cutting Tools." It is FREE to all mechanical executives.

C. H. Rooke Ltd., has been incorporated at Ottawa with a capital of $50,000 to carry on the business of manufacturers and distributors of Delco-Light products, gasoline engines and electrical devices etc. Head office is at Toronto and the incorporators are Francis P. Dawson, John E. Corcoran and William B. Horkins all of Toronto.

BUILDINGS

Toronto, Ont.—City Architect Pearse has granted a building permit to A. P. Morton to erect a brick garage at 248 Victoria Street at a cost of $12,000.

Hamilton, Ont.—The Board of Control have decided to give the Board of Education the extra $30,000 needed to build the proposed addition to the Adelaide Hoodless School. Debentures to that amount will be issued.

Toronto, Ont.—The Board of Education have received a permit from the City Architect to erect a three-storey brick school on the north side of Orde Street, near McCaul, at an estimated cost of $75,000. This is an addition to the Orde Street School.

Toronto, Ont.—The Board of Education has made the following appropriations:—The sum of $90,000 for the erection of a new school building, to contain at least 15 class rooms, for the relief of Winchester and Rose Avenue Schools; $12,000 for the completion of the assembly room at the North Toronto High School; while $15,000 was passed for the erection of a building to furnish more room for the supply department of the Board. An additional item of $50,000 for six additional rooms at Dewson School was inserted, and a total amount for sites and enlargements, amounting to $647,000, was passed.

RAILWAYS—BRIDGES

Calgary, Alta.—The C.P.R. will build a number of section houses and stations and also lay 8½ miles of pipe lines in this district.

Toronto, Ont.—The C.P.R. has filed the preliminary plans with the city for the construction of the double track from the new North Toronto station to Leaside. The plans include a new bridge at Summerhill Ave.

Toronto, Ont.—The Provincial Department of Highways will shortly be in a position to place at the disposal of municipalities standard bridge plans that will mean a saving of thousands of dollars every year. For some time past the engineers of the department have been at work preparing model plans of different types of bridges used in connection with county and township road construction, and these when ready will be supplied wherever needed.

CONTRACTS

Ottawa, Ont.—The General Supply Co. have been awarded a contract by the Works Department for two motor flushers, to cost $7,815 each.

PERSONAL

Tracey E. Freeman, B.A.Sc., who has had charge of the Montreal sales office of Canadian Hoskins, Ltd., for the past eighteen months, is being transferred to the head office in Walkerville, Ont., as assistant general manager.

Capt. James Murray, one of the oldest captains on the lakes, passed away on February 21, at Clayton, N.Y. The deceased was born about 75 years ago in Ireland, but came to Canada at an early age and went into the marine business. For many years he was known in marine circles as one of the most capable of officers in handling boats for the Montreal Transportation Co. During the past year he had been retired.

J. H. Pillsbury, superintendent of the drydock at Prince Rupert, B.C., has been to Vancouver to arrange for engaging a staff and buying ship chandlery general stock for the plant. Mr. Pillsbury came from Winnipeg, where he was authorized by the G. T. P. officials to supervise the installation of a permanent staff. This will enable the plant to bid for all ship repair and overhauling jobs, construct wooden ships, and smaller types of steel craft.

Brig.-Gen. W. A. Whyte, of the Imperial service, was in Toronto recently on a special mission for the British Government concerning the manufacture of munitions in Canada, and about which he is preparing a report for the British Minister of Munitions. Before leaving for Montreal, Gen. Whyte expressed himself as being well pleased with the result of his examination so far, and declared that the work of munition factories here was immensely satisfactory.

T. McHattie, master mechanic, Eastern Lines, Grand Trunk Railway System, Montreal, has resigned. He will be succeeded by **W. H. Sample**, formerly master mechanic at Battle Creek, Michigan. Mr. McHattie has been a prominent figure in Montreal railway circles for many years. He came to Montreal nineteen years ago as master mechanic of the Grand Trunk shops, and after nine years' service in that position took up the post of superintendent of motive power on the Central Vermont Railway. He returned to Montreal as master mechanic of the Grand Trunk Eastern Lines in 1910.

MARINE

Victoria, B.C.—The Cameron Genoa Mills Shipbuilders expect to launch the Laurel Whalen, the second of the auxiliary powered schooners, which they are now building, on March 19.

Victoria, B.C.—Capt. J. W. Troup, manager of the C. P. R. Coast steamship service, states that he had been authorized to call tenders for the construction of two car barges to be used in the local trade. The car barges will be of wooden construction, each with a capacity of nine cars. They will have a length of 150 feet and a beam of 46 feet. Plans are now being prepared and bids will be called shortly.

TRADE GOSSIP

The Hull Iron & Steel Foundries, Ltd., of Hull, Que., have opened a sales office at 165 Broadway, New York City, to take care of their export business.

Trade Enquiries.—The Department of Trade and Commerce, Ottawa, has received the following enquiry, No. 579 for carbon twist drills. A London firm invites offers from Canadian manufacturers of carbon twist drills who can fill orders for export, particularly to Russia.

Japs Building Ships.—It is reported that a Japanese shipbuilding firm building stock boats on speculation has sold seventeen of them to British owners for delivery within the next six months. The tonnage involved is stated at 159,000 tons dead weight, the transaction being completed at a rate of about $215 a ton or more than $30,000,000 in the aggregate.

Lake Boats Change Hands.—W. C. Richardson & Co. has added two more boats to its fleet, having purchased the steamer Frontenac and the barge Chattanooga from the Grand Island Steamship Co. The boats which have been operated by the Cleveland Cliffs Iron Co. have been turned over to the new owners. The Frontenac has a carrying capacity of about 3,200 tons and a keel length of 270 feet, a 40-foot beam, and is 24 feet deep. The Chattanooga is a wooden vessel with a 308-foot keel, 45-foot beam, and is about 4,000 tons gross.

B. C. Wood Products Export.—The export of shingles from the port of Vancouver to the United States in 1916 amounted to $4,050,078, as against $3,790,763 in 1915. Pulp also showed a large increase, the figures being $554,397 in 1916, as against $203,620 in the previous year. There was a drop in shingle bolts from $15,195 to $7,522. Logs showed a falling off from $895,344 to $579,218, and lumber, which includes ceiling, flooring, siding and ties, amounted to $1,127,888 in 1916, against $1,711,498. Paper increased to $1,209,466, compared with $1,002,557 in 1915. The total value of the wood products was $7,666,461, compared with $7,698,707 in 1915.

Mineral Resources Near Kingston.—Mineral resources of the Kingston district in Ontario are attracting increased attention, according to United States Consul Felix S. S. Johnson. The iron mine near Trenton, closed for many years, has been reopened and large shipments of ore made to the United States. This ore is mixed with other ore in the manufacture of steel. Export figures for the district show several thousand tons shipped. Large bodies of mica have been discovered north of Kingston recently. American capital is interested in several properties in the Sydenham district. Since the war began there has been a greater demand for Canadian mica than heretofore.

Business With Russia.—Owing to the special importance, at the present time of establishing commercial connections, on a firm basis, between the allied countries, with the object of ousting German intervention and competition, the Russo-British Chamber of Commerce at Petrograd requests all British firms wishing to trade with Russia now or after the war to send their catalogues and price lists (not less than 10 copies) to the Chamber. The catalogues in question will be placed in the special library of the Chamber, and will be distributed to Russian merchants interested in the development of their trade connections with England. They are to be addressed to the Russo-British Chamber of Commerce, 4 Gorochovaia, Petrograd, Russia.

Lake Steamers for Ocean Trade.—Advices from Cleveland, Ohio, state that, according to the Shipping Act, American ships cannot be transferred to foreign registry without approval of the Shipping Board, but, if that can be secured, a number of lake steamers will be sold for salt water service before opening of navigation and will be placed under British registry. Options have been taken by unnamed Canadian interests on eight package freight steamers and, if the Shipping Board approves, sales may be closed at an early date, as the boats will have to be cut in two so as to pass through the Welland Canal. It is understood a good price has been offered for package freighters.

Russian Buyers Arrive.—A Russian purchasing commission has arrived in Ottawa and opened offices to secure supplies for Russia, both for military forces and the civil population. It is expected that Russian orders placed in Canada this year will aggregate millions. For some months the Canadian Government has felt that of Russian orders being placed in America a great proportion was not reaching Canada. Sir Robert Borden made representations to the British authorities and they pressed the claims of Canada on the Russian Government. After many months negotiating, the result is an imperial Russian purchasing commission for Canada with authority equal and similar to the corresponding body in the United States.

Hurts Canadian Trade.—Canadian manufacturers, importers and exporters are being hit rather hard by the trade restrictions of the British Government which the war developments has made necessary. Nine-tenths of the mail in the Trade and Commerce Department these days refers to the prohibition or restrictive methods in force, and while they are not new, many firms apparently are only awakening to the fact that such regulations have been imposed. The restricted import of machinery and machinery parts, and the export of wood and paper, give rise to the greater number of complaints. All the department can do is handle each case through the High Commissioner, but, generally speaking, the regulations are being adhered to.

Canadian Firm's Activities in Latin-America.—Jenkins Bros., Ltd., Montreal, the well-known manufacturers of brass and iron body valves of every description, have more securely entrenched themselves in the leading markets of

South America, having lately sent a special representative to look over the situation with a view to extending trade relations there. The territory having been traversed successfully, a follow-up system has been inaugurated whereby their products will be given all publicity possible. In this connection they have issued new catalogues, one No. 8-S., printed in the Spanish language, and another, No. 8-P., in Portuguese, both of which fully describe and illustrate valves and mechanical rubber goods suitable for the requirements of up-to-date power and industrial plants, mines and office buildings.

Train Returned Soldiers at McGill.—The Faculty of Applied Science of McGill University, Montreal, has, subject to one week's notice, agreed to place its workshops and drafting rooms at the disposition of the Military Hospitals Commission, for the training of those returned soldiers who, through their loyalty to their King and country, are no longer fitted to follow their former occupations, and must be trained into other occupations that they may be self-supporting. The work has, to the present, been carried on at the Grey Nunnery with success, but so great has become the demands on the Military Hospitals Commission that other classes and other schools must be had. The new hospital, formerly the Loyola College, on Drummond Street, will be available shortly, and, besides the McGill workshops, the Technical School, on Sherbrooke Street, will also be utilized to carry on the work of re-educating the convalescent soldiers.

The Carbon & Alloy Steels Co., Ltd., has obtained a Dominion charter, with an authorized capital of $1,500,000, and will erect furnaces and a foundry plant in Hamilton, Ont., for the manufacture of steel castings, ingots, etc., by the Moffat electric process. The company will also take over the Moffat-Irving Steel Works of Toronto, which will be moved to Hamilton and added to the new plant. Plans have been prepared by Prack & Perrine for buildings that will cost about $100,000. The main building will be 60 ft. wide and 400 ft. long, while subsidiary buildings will cover an equal area. Another $200,000 will be spent on furnaces, electrical equipment, conveyors, cranes, compressors, and general machinery. The plant when fully equipped will give employment to about 250 men, and will have a gross capacity of 32 tons of molten steel per 24 hours. The incorporators are: J. B. O'Brien, K.C., president, Moffat-Irving Steel Works, Toronto; H. J. Waddie, Esq., President, Canadian Drawn Steel Co., Hamilton; J. W. Moffat, Esq., vice-president, Moffat-Irving Steel Works, Toronto; John G. Gauld, K.C., Gauld, Langs & Cresthwaite, Hamilton; W. E. Vallance, Esq., late of Wood, Vallance & Co., Hamilton.

CATALOGUES

Sight Feed Lubricators.—Two bulletins have been issued by the Penberthy Injector Co., Windsor, Ont., describing and illustrating the "Peerless" and new "Polar" sight feed steam lubricators.

Ball Bearings.—The Rochester Ball Bearing Co., Inc., Rochester, N.Y., have issued Bulletin No. 10, which is a descriptive price list covering the "Rochester" ball thrust bearings. The bulletin contains a description of the bearings and tables giving the principal dimensions and prices.

Automatic Plate Valves.—The Mesta Machinery Co., Pittsburgh, Pa., are distributing a new bulletin dealing with the Mesta automatic plate valves (Iversen Patent). The principal features and general construction of the Mesta valve are described in detail accompanied by illustrations. The suitability of this valve for use in air and gas compressors and blowing engines is mentioned in this bulletin.

Water Heaters.—The Alberger multihead water heater for hotels, office buildings and factories, is described in a Bulletin No. 201 recently issued by the Alberger Heater Co., Buffalo, N.Y. The principal constructional features of the multi-head heater and their advantages are described fully, special reference being made to the method used in the heater to accommodate unequal expansions. The bulletin is illustrated.

Drilling Machines. — The Rockford Drilling Machine Co., Rockford, Ill., have issued a series of circulars in a loose leaf binder featuring an interesting line of Rockford drilling machines, ranging from sensitive drills to gang drills. The various types are illustrated, accompanied by a brief specification covering the principal dimensions. Other lines illustrated and described include the "Rockford" Hi-Speed auxiliary heads, horizontal drilling, boring and tapping machines, and tool grinders.

Galt Sprinkler Stoker.—The Galt Foundry Co., Galt, Ont., have issued an attractive catalogue dealing with the economic and smokeless burning of coal, including lignite, and at the same time featuring the Galt sprinkler stoker. A full description is given of this type of stoker, and its principal feature dealt with in detail, accompanied by numerous illustrations showing the construction and application to various types of boiler. The concluding pages contain some useful engineering data covering evaporation formulae, heat values of coal, feed water calculations, miscellaneous tables, etc. The catalogue also contains instructions for reading the slide rule, accompanied by diagrams. The McNaughton rocking sectional grate bar is also described and illustrated. The catalogue is well gotten up, being printed on coated paper, with exceptionally clear half-tones.

Realism in Calendar Art.—Armstrong, Whitworth, of Canada, Ltd., have had prepared for distribution to their clients a Wall Calendar which is at once realistic of a departmental activity of their plant at Longueuil, Que., and a highly creditable example of the art of calendar production. We understand that only a limited number of the calendars are now available, but these will be mailed on request while the supply lasts. The calendar, which has a monthly "tear-off" slip covering each month of 1917, measures 14 ins. by 21 ins. A facsimile on a reduced scale of the pictorial feature of the calendar will appear in the "Armstrong, Whitworth" advertisement on the outside front cover of our March 8 issue.

Black Sheets.—An interesting booklet has recently been published by the American Sheet & Tin Plate Co., Pittsburgh, Pa., entitled "Black Sheets and Special Sheets." The several products are briefly described in conjunction with the trade designations, covering numerous grades of varying degrees of finish, tenacity and other distinctive qualities. For the convenience of the trade, such finishes as are of special qualifications have been grouped under the industry responsible for their origin. The booklet contains some useful tables, including weights of painted roofing and siding, U. S. standard gauge, thicknesses of steel sheets, and a bundling table of black sheets, etc. An interesting feature of the booklet is a diagram of the manufacture of steel as used for sheet and tin mill products.

Bellevue Furnaces.—The Bellevue Industrial Furnace Co., Detroit, Mich., have issued an attractive catalogue No. 3, describing and illustrating an interesting line of stock sizes of "Bellevue" furnaces and accessories designed to supply standard equipment for all methods of metal heat treating. The principal features of the various types of furnace, which are adapted for use with oil or gas, are dealt with and the essential dimensions given for each size. Some of the uses to which these furnaces can be put include, melting all kinds of metals, brazing, case-hardening, forging, heat-treating tempering, rivet heating, tilting and tool furnaces, etc. The catalogue contains 68 pages with index and is fully illustrated.

BOOK REVIEW

"The Tractive Resistance on Curves of a 28-Ton Electric Car".—The subject has been investigated by the Railway Department of the Engineering Experiment Station of the University of Illinois. The results which are set forth in bulletin No. 92 of the station establish, for this car, the relation between curve resistance and speed, and between curve resistance and rate of curvature; the ratio in both cases is direct. Tests were conducted upon each of seven curves on the lines of the Illinois Traction System, the curvature of which varied from 2 to 14½ degrees. Test runs were also made over tangent track adjacent to the curves. The tests were made by Professor E. C. Schmidt, and H. H. Dunn. Copies of this Bulletin may be obtained gratis by writing W. F. M. Goss, Director of the Engineering Experiment Station, Urbana, Ill.

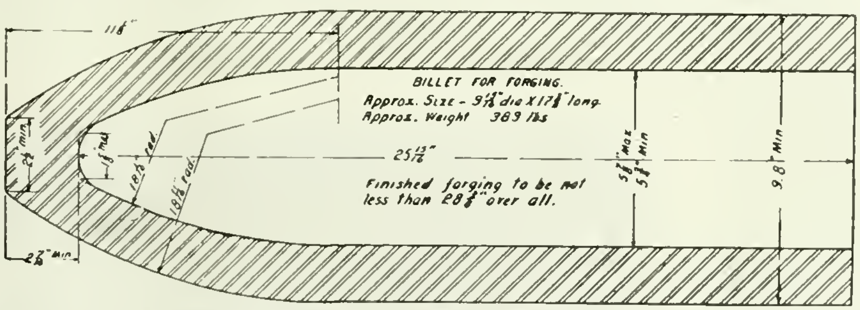
Machining 9.2 ins. H. E. Shell in a Structural Steel Plant

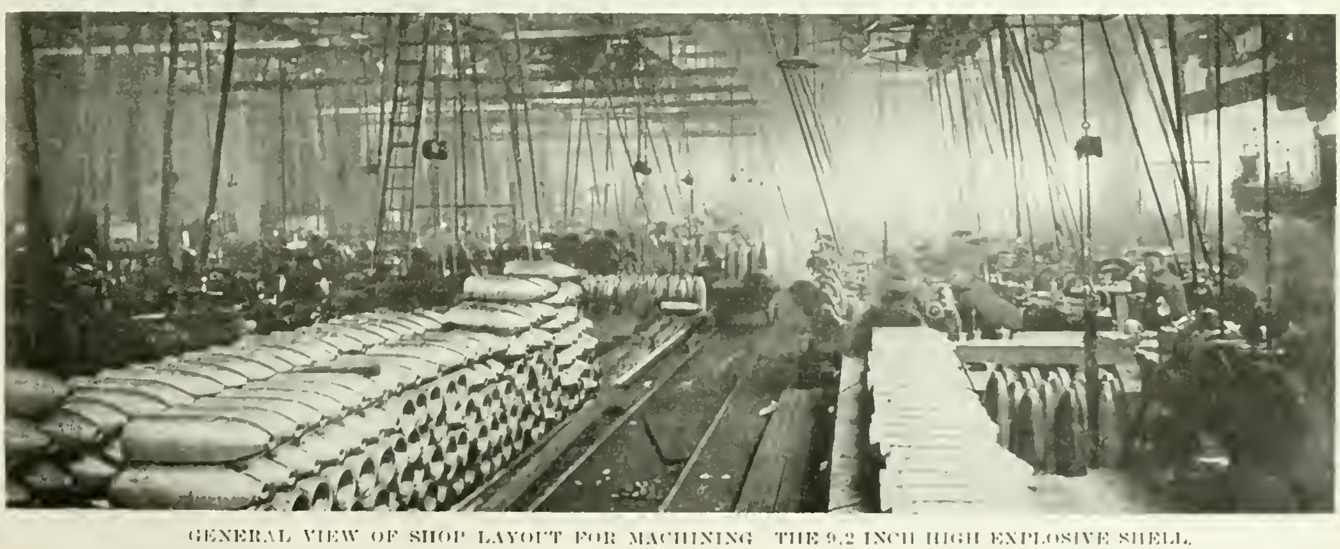
Staff Article

The success that has attended shell-making in Canada has been unrestricted in the sense that neither size nor type of shell, nor their accessories, have proved themselves in the nature of stumbling blocks to any extent, and that where difficulty has been experienced, it has been overcome quite promptly and permanently. From the known variety of plant engaged in munitions production, such a state of affairs, is, to say the least, highly satisfactory.

MACHINING the 9.2 inch high explosive shell is, in many respects, similar to that on the smaller sizes; as a matter of fact, certain details, such as nose operations, are more or less identical. However, owing to the increased weight and dimensions, the methods of achieving the desired results are such as to call forth the best in individual ingenuity and necessitate, as well, high standard plant equipment. On account of the wire range of engineering ability and experience that has been drawn upon and furnished unreservedly for the work, together with the local color that distinguishes each individual plant, the methods and devices adopted and employed for specific operations are so varied, although of perhaps equal efficiency, that the production of shell—general or in detail—is seldom the same in any two shops. The plant from which the accompanying data were obtained has only been producing the 9.2 inch shell for a very short period; it is, therefore, only of recent date that they have attained to capacity production. Owing to inability to store the rough forgings under cover, the shells as first received are arranged in large piles in the yard crane runway, the crane proving very serviceable in unloading from the cars. The forgings



APPROXIMATE FORGING SIZES OF 9.2 INCH HOWITZER SHELL.



GENERAL VIEW OF SHOP LAYOUT FOR MACHINING THE 9.2 INCH HIGH EXPLOSIVE SHELL.

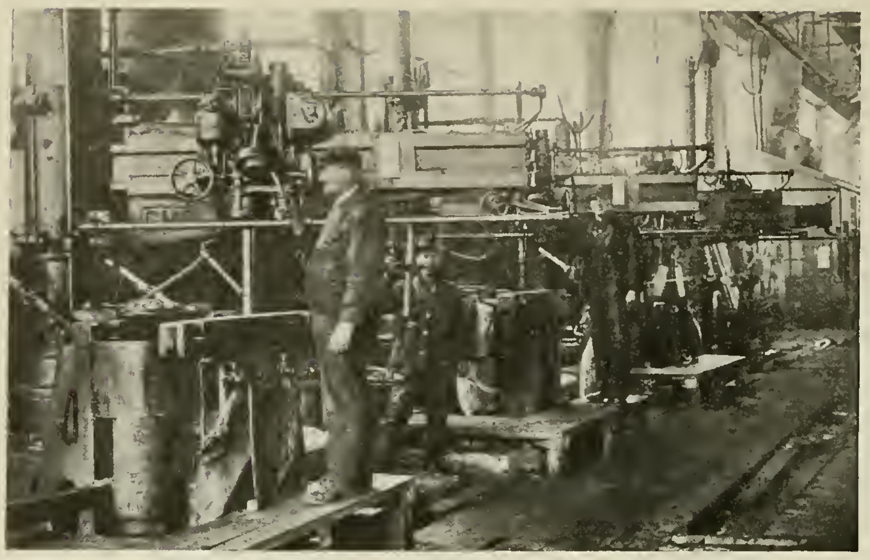


FIG. 1. BATTERY OF FOUR 6 FT. "C.M.C." RADIAL DRILLS OPERATING ON SHELL NOSES.

are piled in rows having distinct heat numbers, and, when required, are rolled on slightly graded wooden runways through openings in the wall, entering the machine shop at a point adjacent to the radial drills that perform the first operation, that of rough drilling the nose. It might be here stated that these openings in the walls are somewhat larger than the shells and are covered with stiff canvas that allow the forging to enter and then fall back to close the aperture. This method of delivery from the outer yard to the shop not only provides a convenient means of handling the shells but does away with the opening and closing of doors, which in very severe weather is not greatly appreciated by the nearby workmen.

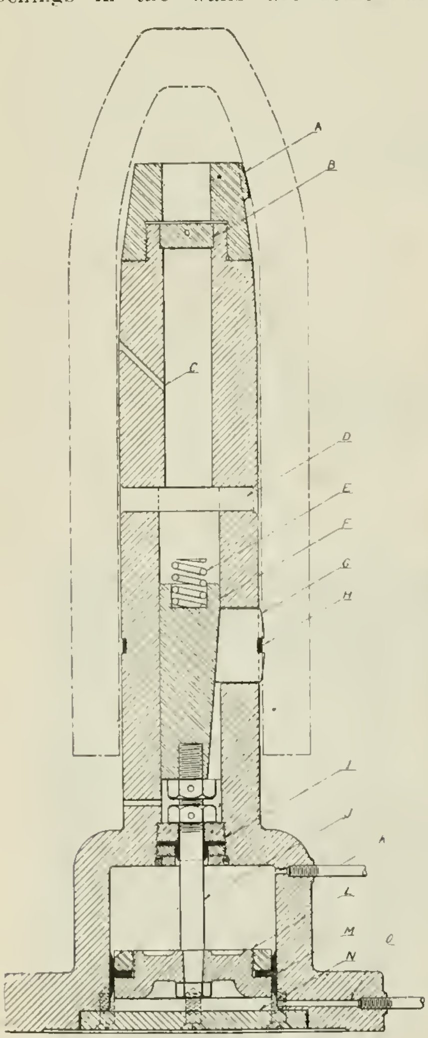

FIG. 2. AIR CHUCK FOR CENTERING WHILE DRILLING HOLE IN NOSE.

Drilling and Facing the Nose

The rough forging is approximately 30 inches long and 10 inches in diameter, and, as just stated, the first operation is drilling the hole in the nose. This is accomplished in five-6 ft. radial C.M.C. drills, fitted with special fixtures, and of ample weight and strength to eliminate all possibility of spring, thus insuring efficient accuracy when drilling. Fig. 1 shows a row of these drills working on this operation, each machine having a capacity of about 125 per day. When the shell is received from the outside, it is placed in a vertical position and by means of an air hoist, with a lift of about 40 inches, is raised and placed over a vertical post secured to the center of the drill fixture, which in turn is firmly bolted to the base plate of the machine. The jig is of the duplex type, which permits the placing or removal of one shell while the tools are working on the other. A sketch of the central post for chucking the forging is shown in Fig. 2. This is of the pneumatic type, the operating cylinder being located at the base of the post. When the rough forging has been dropped in place, the inside profile rests upon the three point steel piece A, which is screwed to the upper end; the small plug B being driven into the top to prevent the cuttings from dropping into and injuring the interior mechanism. The air is allowed to enter the opening K, thus depressing the piston L, which is secured to the wedge block F by means of the rod J, which passes through the stuffing box I. By the downward movement of the wedge, the three jaws G are forced out to grip the inner surface of the shell near the base, and are released by means of the heavy flat spring H. The coiled spring E acts as a cushion when the wedge is pushed upwards. Two small holes are drilled in the post to allow the air to escape freely. The base is sealed by the disc N, held in position by the screws shown.

Following the setting of the shell, the cross-bar which carries the central guide bushing is swung into position and locked by means of a slot at the front of the fixture. Flat twisted Celfor drills of $1\frac{5}{8}$ inches diameter are used

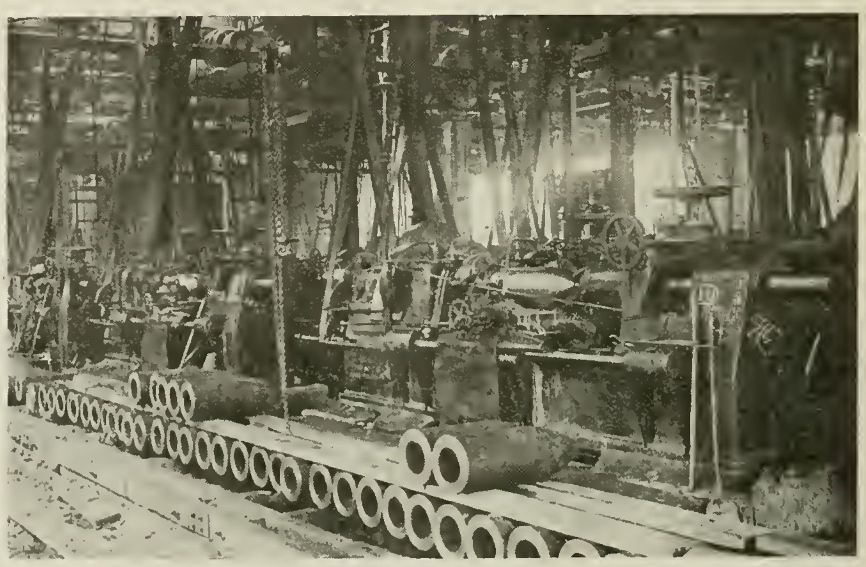

FIG. 3. ROUGH TURNING SHELL BODIES—"A.M.C." LATHES.

to perform the drilling; the operation being aided by a copious supply of forced lubrication. The thickness of the metal at this point is about three inches, but the nose is faced off so that the depth is roughly $2\frac{5}{8}$ inches, as indicated in Diagram I of the Operation Chart. After facing, the shell is removed from the fixture, the hole gauged for size, and the base marked for cutting off. The device used for this purpose consists of an inverted L shaped forging, carrying a 1⅝ ins. pin to fit the hole in the nose, and at the lower end of the

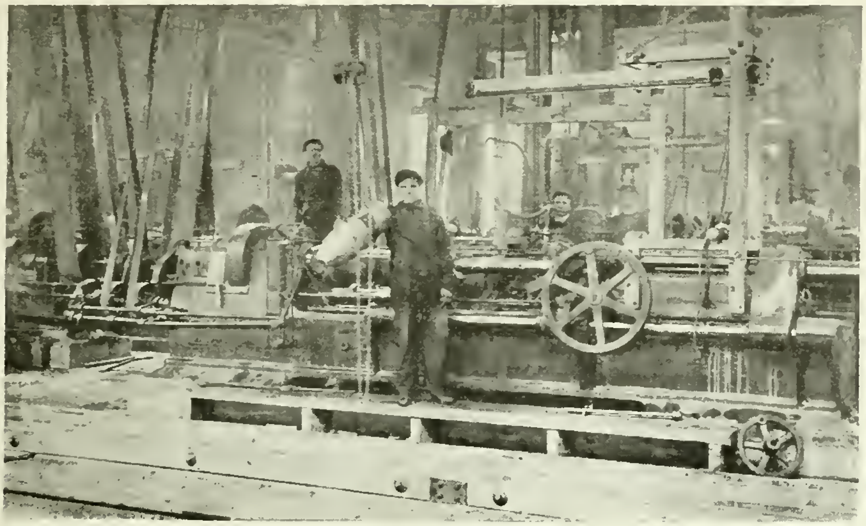

FIG. 4. "A.M.C." LATHES ON ROUGH AND FINISH BORING. ILLUSTRATION SHOWS SHELL BEING REMOVED FROM LATHE.

long arm a spring center punch is provided, by means of which several indents are made around the shell. As each shell leaves the first operation, a progress tag, secured to a piece of wire, is placed in its nose, this tag remaining with that particular shell as it passes from one machine to another.

Cut Off and Rough Turn

The second operation—cutting off the open end, is performed in five No. 12 Hall machines. The punch marks just spoken of indicate the length of the shell, which should be 27 1-16 inches, with an allowance of 1-32 inch above or below this dimension. For the rough turn operation, twenty Amalgamated Machinery Co. machines are employed, each having a capacity of over 30 shells per day. The entire length of the shell is turned at one setting; the shell being driven from the base end by means of a self acting three jaw (spring) arbor, a special split plug being placed in the nose end to receive the tail center. The contour of the nose is turned by the action of a solid point travelling on a cam placed at the rear of the lathe. Contact is maintained by means of suitable bell-crank levers having adjustable weights. Owing to the fact that accurate forging is next to impossible, all elementary machining operations are accomplished by gauging from the interior walls, thus making the work on the boring machines more uniform. It is obvious therefore, that in rough turning the outside, the cut may be irregular in proportion to the variation in wall thickness, but the average depth of cut will be from ¼ to ½ inch. The profile radius is 18.4 inches, the tangential point being 10.72 inches from the nose end, while the parallel portion has a diameter of 9.32 inches, with an allowable variation of .03 inches either way.

In passing the shells from one operation to another, very little trucking is done, as a network of wooden runways are provided upon which the shells are easily rolled from one position to another as required.

Rough and Finish Boring

Twenty special boring lathes of Amalgamated Machinery Co. make are operating on the rough and finish bore, both processes being accomplished at the one setting of the shell. Special chucks similar to that shown in Fig. 8, but longer, are used. The hole in the nose is placed over the pin secured in the center of the face-plate, while the outer end is held central by means of a three point clamp, hardened serrated jaws being inserted to grip the shell. The cutter bars are held by means of a tapered shank to the heavy tail-stock spindle; the drive being obtained by a floating clutch collar placed over the bar just previous to inserting in position. To conveniently handle these bars, a small block and tackle is provided, this being supported upon a light overhead runway, as shown in Fig. 4. The roughing bar carries four staggered notched cutters for roughing out to 6.46 inches diameter. The finishing bar is then used to rebore to 6.5 inches diameter. In order to eliminate unnecessary work at a later stage, this plant adopted a method of setting the working depth of the bars on the interior profile that has proved very efficient. This was deemed advisable owing to the difference in tolerance between the nose depth and the overall length. A special bush, having the desired depth of nose metal, was placed over the centering plug in the face-plate, and, with no shell in position, the bars were forced against the bush and suitable feed stops adjusted to the proper length. By adhering to this method, it was found that increased accuracy could be better maintained. Each bar is provided with a special quick acting coupling for connecting the lubricating hose. It might be here stated that the cutting compound for all the heavy turning and boring machines is distributed to the various sections of the shop by means of a force pump, centrally located. Half ton Reading chain blocks are furnished to each of the heavy machines.

The profile cutters used in the boring bars are first sawn from bar stock, and afterwards cut to shape in a special fixture secured to the table of a small boring mill; the use of a parting tool permitting the surplus stock to be used for tipping tools. After drilling the clamping and dowel holes in the cutters, they are placed on a milling fixture, one on either side of a master cam, and milled to the desired contour; a roller being located between the two cutters on the arbor. They are then hardened and

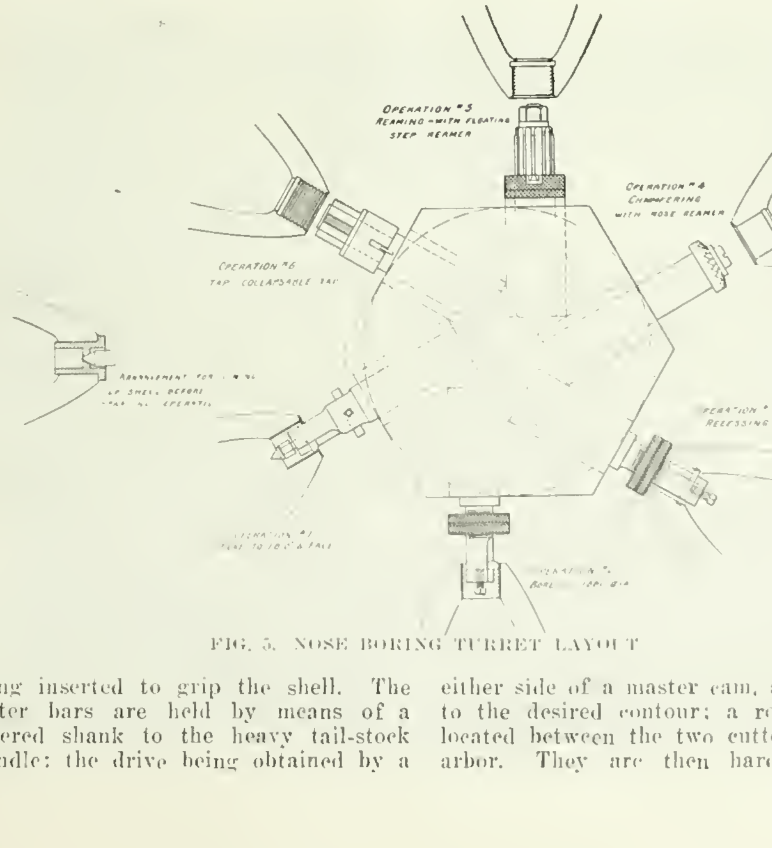

FIG. 5. NOSE BORING TURRET LAYOUT

tempered, and finally ground to gauge on a special attachment fitted with an electric grinder, the arc movement being

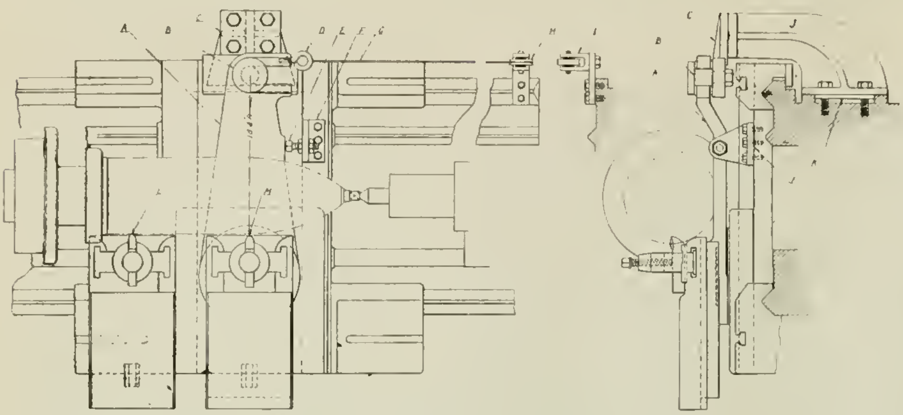

FIG. 6. LAYOUT OF FINISH TURNING DEVICE.

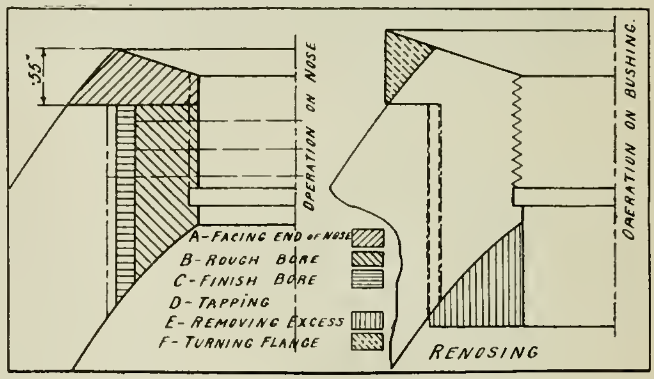
about 30 degrees and the radius $16\frac{1}{4}$ inches.

Machining the Nose

The sequence of operation at this stage is shown in Diagram V. of the Operation Chart, the tool layout being seen in the sketch Fig. 5. The different sections illustrate the progressive stages of turret operations. When placing the shell in position, a special bush is inserted in the nose for the purpose of obtaining proper alignment; this is seen to the extreme left of Fig. 5. The steady-head being adjusted, the bush is removed and the nose roughed out to 1.810 inches diameter, and the front faced. It is again bored to a diameter of 1.881 inches, following which a recess is formed, .175 inches wide at a distance from the nose of 1.8 inches, the maximum diameter being 2.008 inches. A rose reamer then faces the nose to an angle of 18 degrees. The hole is finally reamed with a floating step reamer to a diameter of 1.906 inches; the diameter below the recess being 1.825 inches. A Victor collapsible 14 thread, R. H. tap completes the operation of machining the nose.

Through defective forging or subsequent machining, it is sometimes necessary to resort to the optional method of enlarging the nose to take a separate bushing. To prepare the shell nose for this bushing, the machining shown in the adjacent renosing operation sheet, renosing is necessary. Metal is cut from the face to a depth of .55 inch, and the bore enlarged to 2.393 inches, rebored to 2.410 inches, and then tapped 14 threads per inch. When the bush is put in position, the portions shown shaded in the chart are then removed. Eleven Advance-Rumley machines are working on this operation, each having a capacity of about 90 shells per day.



RE-NOSING OPERATION SHEET.

Finish Turn and Profile

This operation is practically a duplication of the rough turning but involving greater accuracy. The method of forming the nose profile is different, inasmuch as the contour is derived by means of a radius arm in place of the stationary cam. Two tool posts are provided; the one operating on the parallel section being secured to the forward portion of the lathe saddle. A sketch of the arrangement is shown in Fig. 6. The radius arm A is an extension of the lower portion of the cross slide rest; the pin B, whose center is definitely set at a distance of 18.4 inches from the cutting tool M, being secured in a permanent position to the bracket C, the lower portion of which is rigidly bolted to the bed of the lathe. When operating on the profile (the cutting generally commencing at the nose), the radius arm is held firmly against the pin B by means of the cable G secured to the eyebolt D, the opposite end of the cable carrying a heavy weight. Secured to the saddle is the bracket F which carries the adjustable stop E which makes contact with the radius arm when the cutting tool is at the tangential point of the profile and parallel portion. As the saddle continues its forward movement, the tool M will follow in the path of the tool L, the finished surface leaving no evidence of double tooling. The radius of the profile is the same as that on the rough turn, but the tangential point is located 10.62 inches from the nose. The finished outside diameter should be 9.155 inches, with a high and low tolerance of .01 inch. For about three inches at the base the diameter is reduced to 9.055 inches with the same limit allowance.

Wave and Groove for Copper Band

This operation is performed on eight Root & Van Dervoort special machines, each of which is provided with four tool turrets and a single post at the rear. The progress of the work is clearly shown in the Operation Chart, Diagram VII. By means of the rear tool the groove is sized for width of 2.565 inches,

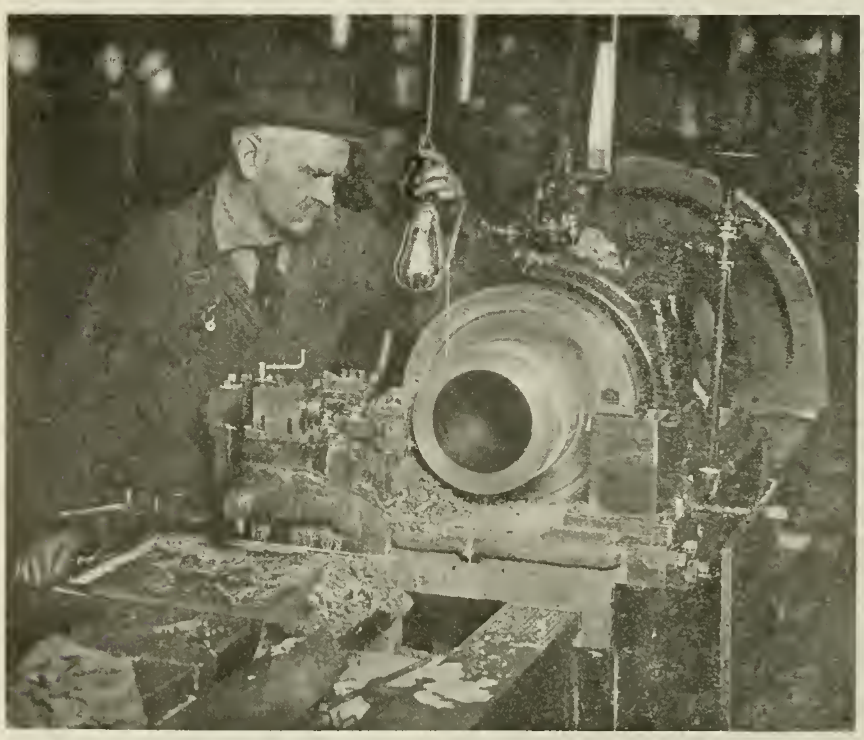


FIG. 7. WAVING AND GROOVING—"R. & V." MACHINES.

the center being 24.42 inches from the nose of the shell. These tools cut to a diameter of 8.7 inches with an allowable variation either way of .02 inch. The gang tool in the turret then cuts to the same diameter, after which the remaining stock is swept out with a broad nosed tool. The undercutting is next performed, both tools advancing simultaneously at the desired angle by means of a small hand-operated worm and gear with pinion meshing in rack cut in the top of each tool. The waving is afterwards accomplished, the oscillation being obtained by a roller in contact with a cam on the chuck face. This operation is seen in Fig. 7.

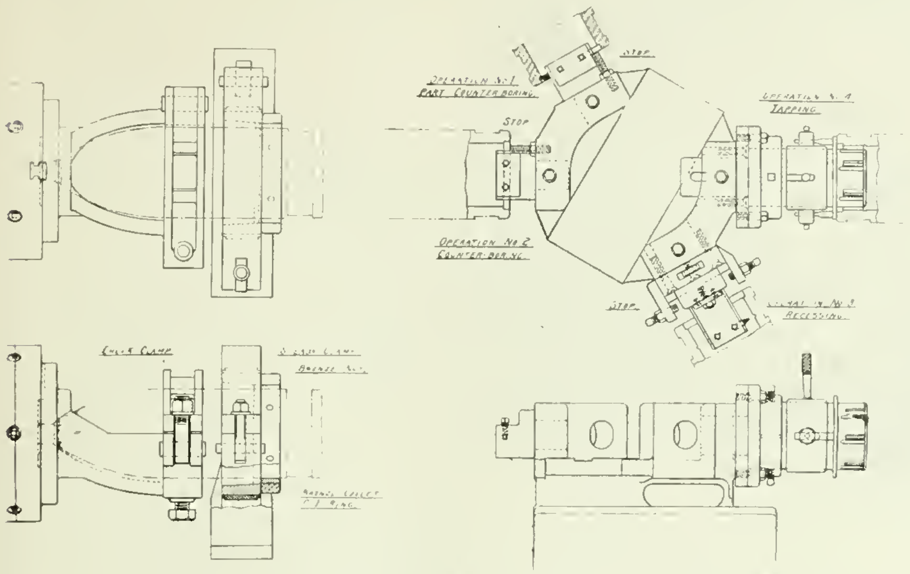

FIG. 8. LAYOUT OF TOOLING FOR BASE BORING AND TAPPING.

Base Boring for Adapters

After the groove for the copper band has been cut, the shells are machined in the base to receive the adapters. Nine Steinle turret lathes fitted with special chucks and steady-heads are employed in this operation, each machine having an output of about 70 shells per day. As shown at the left of Fig. 8, the chuck is of the semi-enclosed type, the clamp providing the necessary drive. This clamp is swung clear, while shell is being placed in or removed from the chuck. As indicated in the sketch, the nose is placed over a plug in the centre of the face-plate, while the outer end is supported in the steady-head. This steady-head is of special design, being fitted with an adjustable bronze collet bushing to allow for the slight variation that arises through the high and low limit tolerance. The three component parts of the adjustable collet are shown in Fig. 9. The outer diameter of the ring A revolves in the babbitt bearing of the steady-head, while the inner conic surface conforms to that on the outer diameter of the split collet B which is adjusted to the shell size by the movement of the nut C.

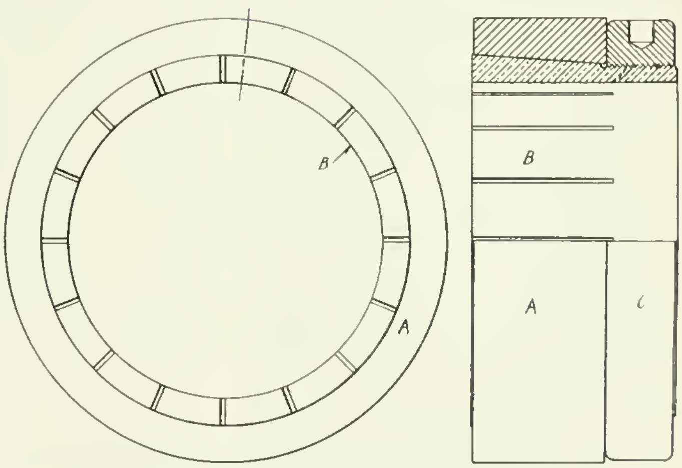

FIG. 9. STEADY HEAD BUSHING.

The turret tool layout is shown in Fig. 8, the order of operations being indicated on Diagram VIII of the Operation Chart. The end is first faced to a distance of 1.12 inches from the back edge of the rifling band groove. The interior is then counterbored for a depth of .71 inch, and to a diameter of 6.99 inches, after which the recess is cut-in at a distance from the base of 2.28 inches to a diameter of 6.675 inches: this being the root diameter of the thread. The thread is then cut-in with a Murchey collapsible tap, oil being used as the cutting medium. The clamping bolt is eased off while tapping to relieve the tap from unnecessary strain.

Turning and Fitting Adapters

Following a preliminary Government inspection, the shells are ready to receive the adapters, a short description of the work on these may therefore be in order here. While the general practice in most shops of screwing the adapters into position is by means of a pair of holes drilled in the base, the method adopted in this plant is the use of a square of about 2 inches on the side and protruding about ⅞ of an inch from the body of the forging. The blanks are first centered on either end and then turned in the lathe, the pilot and flange machined to about 1-32 inch larger than the finished size, while the portion for the thread is turned to exact diameter of 6.67 inches, after which the shoulders are squared and undercut. The gauging of the thread diameter is accomplished by means of Johansson snap gauges, which are provided with insulated finger grips to insure increased accuracy. A view of this operation is shown in Fig. 10. Eight Advance-Rumley lathes perform the necessary operations. In addition to turning, the

FIG. 10. SIZING ADAPTERS PREPARATORY TO THREADING.

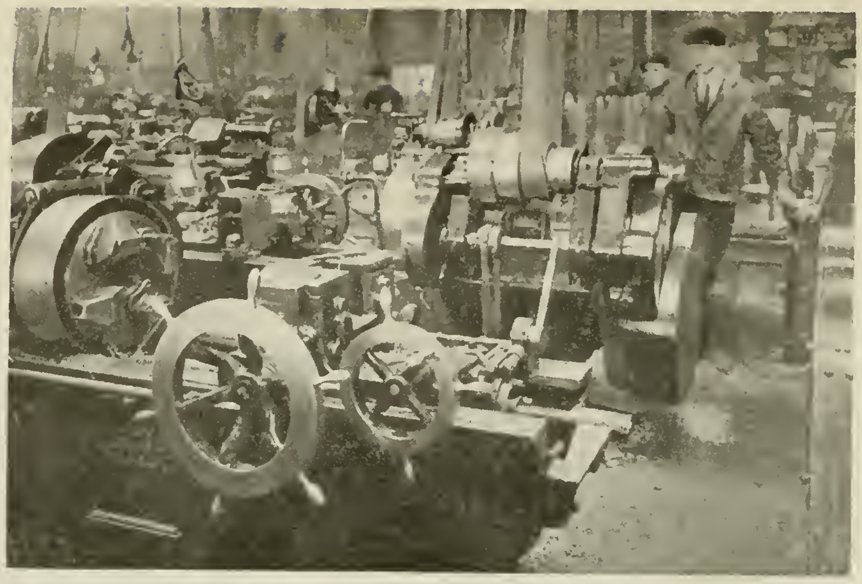

FIG. 11. "LANDIS" BOLT CUTTERS THREADING 9.2 IN. ADAPTERS.

ends are faced off at this setting. The threading is done in two Landis bolt cutting machines, these being shown in Fig. 11. Oil is used on the dies as better threads are produced. To insure the pilot and flange being concentric with the threaded portion, the adapters are gripped in a universal three jaw chuck; the jaws, which are soft, being threaded to suit the adapter.

The adapters are now ready to be fitted in, this operation being performed in the usual way of first screwing in for a trial fit and afterwards coating with Pettman cement and firmly screwing to a final position. It might be mentioned that these are threaded left hand to counteract the action of the shell should they develop a tendency to become loose, while the projectile is in flight. For the purpose of sawing off the projecting squares, three Napier band sawing machines are installed. Final facing is next performed in several Root & Van Dervoort special machines.

Copper Banding Operations

An essential feature in connection with the manufacture of shells is the necessity of securing sufficient and effective compression on the copper band when forcing same to position, and, to be certain that the copper is pressed well into the undercut and waves, the bands are thoroughly heated before being placed on the shells. The copper bands are first heated to a bright cherry red, for which purpose four Ferranti electric furnaces, especially designed have been installed. When heated to the desired temperature, the ring is placed in the press, the shell dropped over it, and a couple of applications of the pressure given, the shell being slightly turned between each movement. The pressure of 2000 lbs. per square inch, used to operate the press, is derived from a three plunger pump; the pump and the press being supplied by the Metalwood Mfg. Co. Fig. 12 illustrates the above unit in operation. In addition to the increased ductility obtained by heating the band, the shrinkage when cooling aids in taking a firmer grip upon the shell.

Machining the copper band is similar to that on all other shells, being accomplished on five Jenckes improved band turning machines made by Warden King Co. Diagram XI on the Operation Chart shows the operations in detail; roughing with a broad nosed tool and finishing with a formed cutter, the large diameter being 9.34 inches, .005 inch variation either way being permitted.

A simple, yet highly serviceable method has been adopted for stamping the base of the shells; this interesting fixture being shown in the sketch Fig. 13. The casting A is machined on one side to a free fit on the diameter at the shell base, and holes broached in the desired location of a size suited to the stencils used. Narrow slots, C are cut in the side of the stamps, and the plates D

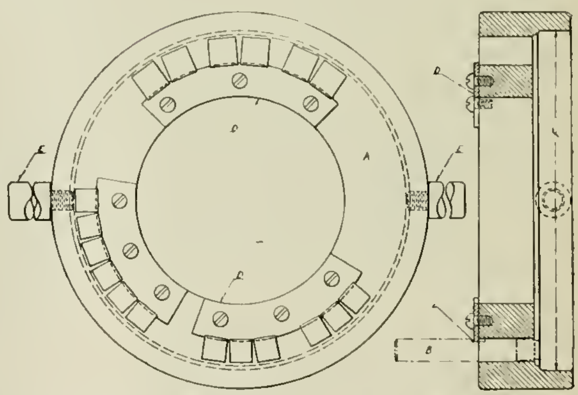

FIG. 13. STENCIL-HOLDING DEVICE.

secured in position, thus eliminating the possibility of the stencils being lost from the fixture. Handles E are provided for the convenient handling to and from the shells.

Machine work is now completed and the shells are given a final inspection preparatory to washing and varnishing. After washing in a soda solution to remove all trace of grease, the interior of the shells are rinsed by a spray of clear water, and, when dry, a bush is screwed into the nose to protect the thread from the varnish. This last process is accomplished in an efficient but rather cumbersome way. Five shells are placed on a specially constructed rack and secured in position, and then tilted beneath a trough having five outlet spouts with faucets to control the flow of the varnish as it passes into the shells. When the shells are filled, the supply is shut off and the rack again tilted to allow the liquid to empty into a receptacle below the fixture, from which the varnish is again pumped up to the higher level. The shells are again inspected, crated and otherwise prepared for shipping.

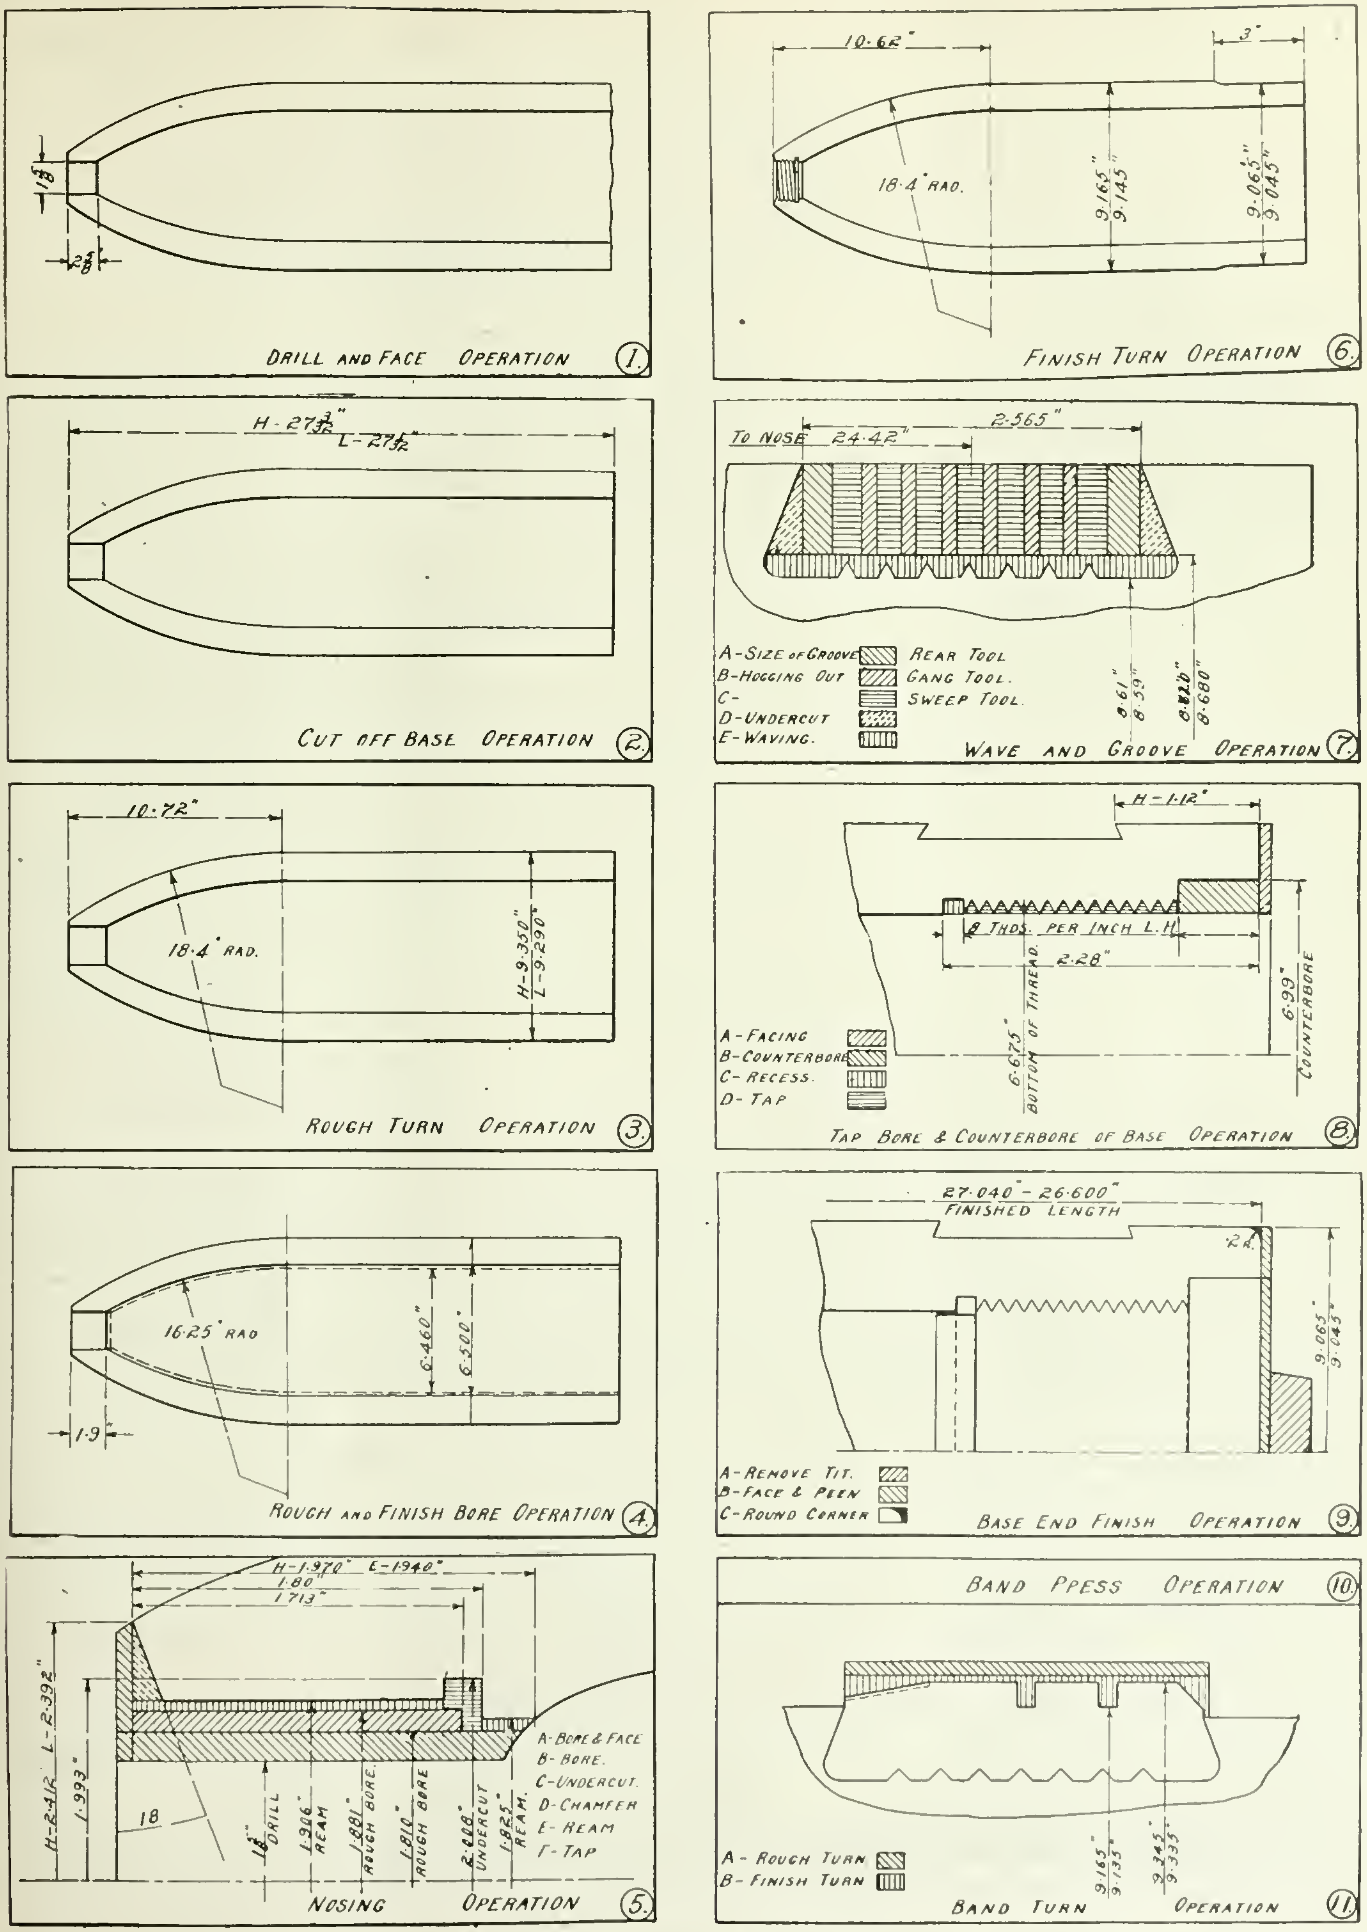

FIG. 14. MACHINING OPERATION SHEETS, 9.2 INS. HIGH EXPLOSIVE SHELL.

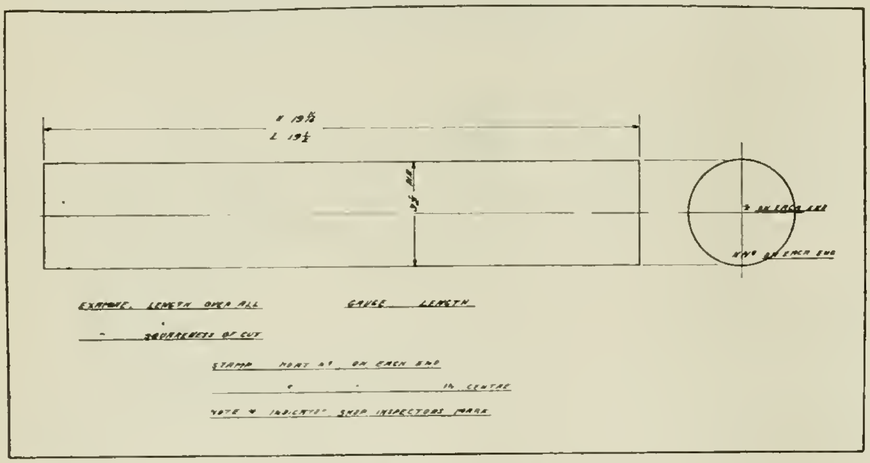
Shop Inspection Routine in 18 pdr. H.E. Shell Production

By A. F. Menzies

The ultimate value of each individual shell, irrespective of its type and size, is wholly dependent on the care taken to have it perfect in material structure, a masterpiece, as well, of mechanical engineering skill, while, at the same time conforming to a weight and measurement stipulation which individually or in combination is only tolerant within the very narrowest limits. The accompanying article features the routine adopted to achieve satisfactory output in a shop recently engaged on the machining of 18-pdr. high explosive shell.

PRINTERS' ink has been lavished on descriptions of the manufacture of shell; but a very important item of manufacture, shop inspection, has been little mentioned. Without adequate shop inspection, the results produced would be mainly scrap. It is not enough that shells be produced which will meet the dimension limits; the weight must be correct, and to obtain this result without light weights and over weights, much closer dimension limits must be worked to than those allowed on the official drawing. For instance, an 18 pdr. H.E. shell that is shorter than the mean allowed length is almost certainly going to be a light one, unless it has very thick walls.



FIRST OPERATION—SAW-OFF LENGTH FOR TWO BILLETS, ALLOWING 3-16 IN. FOR PARTING.

Inspection Between Operations

As a shop inspection which does not examine every shell after each operation is a farce, gauges, in addition to those used on the finished product, must be designed and used. The first matter to be attended to it to make up a drawing of the shell as it should be after each operation, Blueprints of these drawings can advantageously be hung up at the machines, and it is as well to have the special points to be inspected noted thereon. Instructions concerning work's marks on the shells denoting which operator did the work can also be effectively conveyed by this means.

Arrangement of work's marks should also be made. This marking may be done either by the operator or the inspector, if done by the former it should be the duty of the latter to see that the marks are correctly made. The location of these marks should be such that they will, if possible, remain on the shell until the work they guarantee has been proved correct by a subsequent operation. To illustrate, the mark denoting that the shell is correctly rough turned should remain visible until the outside is finished. On all finish operations, the mark should not be removed until after preliminary examination.

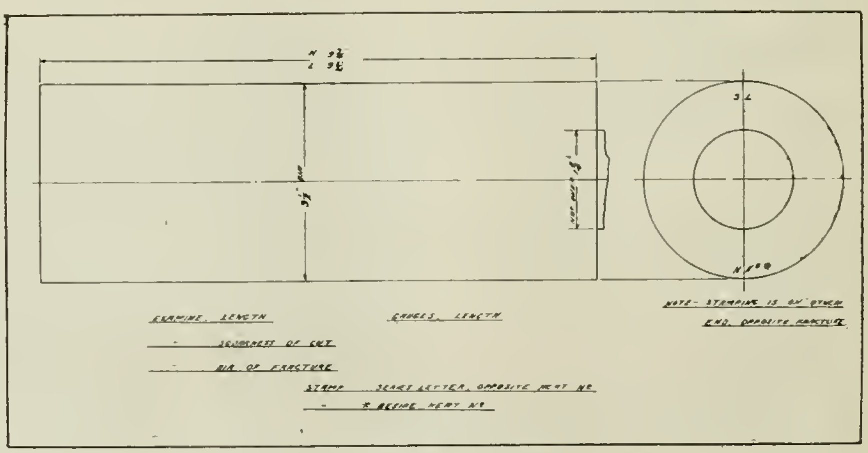
Such procedure enables a defect to be traced back to the parties responsible for it. This fact alone is worth a great deal as it enables a chief inspector to know which of his men is accepting incorrect work. There is nothing more aggravating than to have a large number of rectifications sent out and to have no means of telling which shift accepted them. The average man dodges responsibility and the lame excuses invented on short notice are ludicrous.

For assistants the chief should select men who have a mind of their own, and who will not allow an operator to persuade them that it is good enough. Careful instruction should be given, also intelligent explanation of the various operations and their effect on succeeding ones. The assistants should be instructed to take nothing for granted and to believe only what the gauges tell them. The thing that couldn't happen is well worth watching for. Clearing up the work at the end of each shift should be insisted upon. This is not difficult where the operators are allowed a few minutes to clean their machines.

Variety in Shop Routine

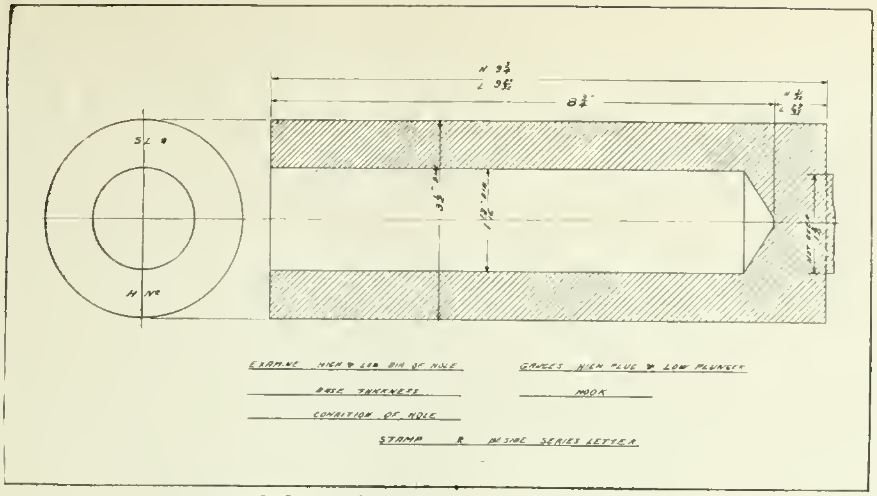
The actual routine of shop inspection will vary, of course, with different shops, on account of different methods of manufacture. The following applied to a shop making 18 pdr. H.E. shells where the chief shop inspector was held responsible, in addition to the actual inspection, for routing the work, keeping track of the series and rectifications, cleaning the shells, and keeping the operators tallies.

The first inspection operation was at the saws where lengths were cut from the bars sufficient to make two shells. The length cut off and the squareness of the cut had to be examined, the former with a length gauge and the latter with the eye. The piece was stamped on each end with the heat number symbol and work mark as shown in Fig. 1. After this the work was counted and passed on to the next machine.



SECOND OPERATION—PART AND BREAK.

The second operation on the piece was



THIRD OPERATION—DRILLING OUT INTERIOR.

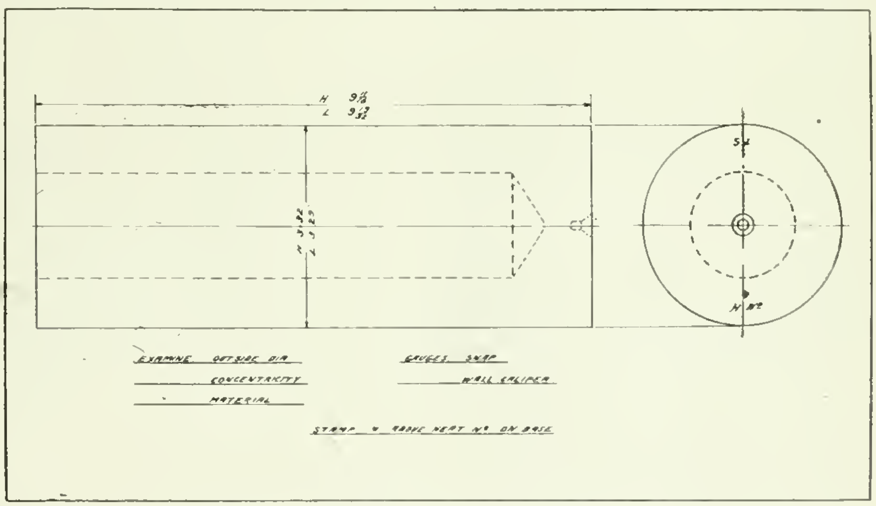
to part it into two billets. The parting was carried down to a diameter of from $1\frac{1}{2}$ ins. to $1\frac{3}{4}$ ins., and the two billets were then broken apart. The inspection required was to check the length and to see that the fracture was not too large in diameter to enter the stop in the drill press chucks. The work was marked as shown in second operation diagram, and, after being counted was stacked in piles, one deep, holding a series (250), for examination of fractures by the Government Examiner. The single pile allowed the examination of the fractured end, and also the placing of the acceptance stamp on the other end. As the marking up to this stage was on the end of the shell that was to be drilled, it had to be kept away from the centre to avoid being drilled out.

Drilling constituted the third operation. Here the size of the hole was examined with a low diameter plunger and a high diameter plug. The hole was looked into to see that it was in good shape and the base thickness was examined with a hook gauge. One arm of this gauge was pointed and touched the bottom of the hole in the centre, while the other arm lay along the side of the shell and had high and low limits marked on it which registered with the base. Checking the base thickness instead of the depth of the hole is the correct method of gauging the drilling, as the billets vary in length and the stop comes on the base, therefore all base thicknesses should be the same. The marking was again on the open end as shown on third operation diagram.

Facing Base and Centering

The fourth operation consisted of facing off the base. The base thickness was again gauged, this time more accurately, with a pillar gauge. The bases were also tested for flatness, and the heat number symbol and series letter transferred from the nose end to the base end. The work mark was as shown in fourth operation diagram. The shells were stacked nose up for Government Examiner to see his acceptance stamp on the open end. They were then reversed, and the acceptance stamp placed on the base. If the acceptance stamp was put on so that it would not be removed in the rough turning or base recess operations there was no need to transfer it again until the shells were put in for preliminary examination.

The fifth operation, centring, may not seem to be worthy of much inspection: but it most certainly is. The centres were tested for depth with a depth gauge in order to see that they had not been drilled so deep that they would not clean out in the base recess operation. About 10 per cent. of the shells were put back on the centring post and spun to see if they had been centred truly with the hole. Neglect of this is a fruitful source of eccentric shells.

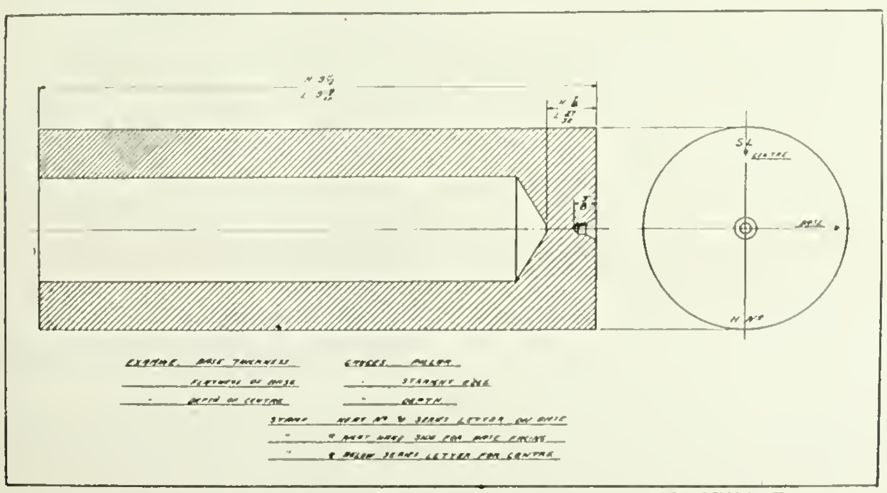


SIXTH OPERATION—ROUGH TURN BODY.

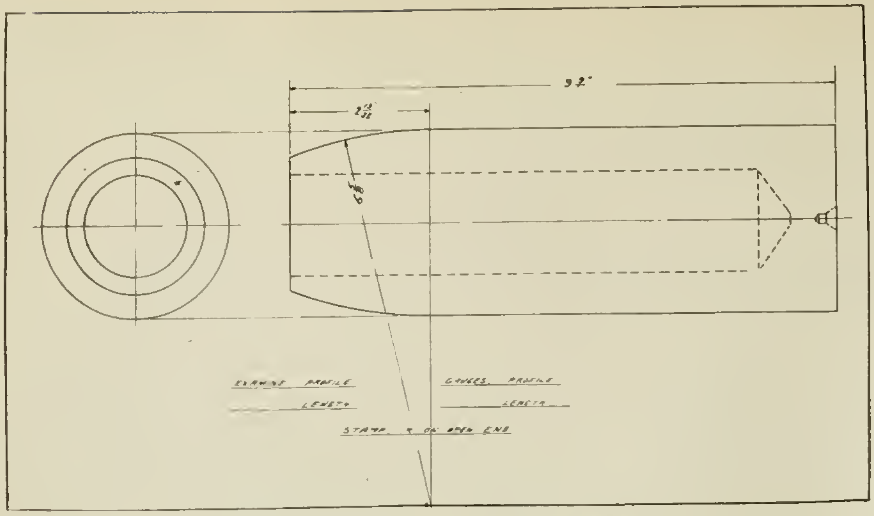
The marking for the centering operation is also shown on fourth and fifth operation diagram.

Rough and Finish Turning and Profiling

After the sixth operation, rough turning, the shells were gauged for diameter with a snap gauge. A careful examination of the material was also made for seams and other defects. When found correct the work was stamped and passed on to the rough nosing operation. This latter was rather important, in that here the shells were all brought to a uniform length. The length was checked with a length gauge and the profile with a gauge laid along the side of the shell. This gauge is not very reliable and the safest way is to put a shell ahead through the profile lathe to see if sufficient stock is being left on for finishing. As in the profile lathe, the work was stopped on the open end, it was necessary to see that the end-facing tool in the rough noser was cutting cleanly and not leaving ragged pieces sticking up which would alter the location of the profile. The work was here stamped on the open end.



FOURTH AND FIFTH OPERATIONS—FACE BASE AND CENTRE.

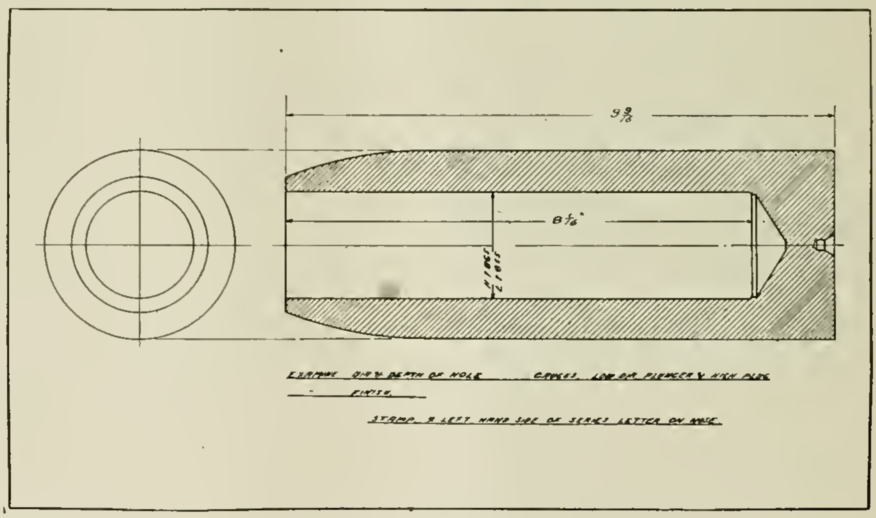


SEVENTH OPERATION—ROUGH NOSING.

The eighth operation, profiling, which also included finishing the outside of the shell, was next. The work was checked with the high diameter ring, the low diameter being gauged with a snap tried on at each end, and the middle. The profile was examined for shape and location, and the heat number and series letter transferred to the nose of the shell. It will be noted that the full heat number was here placed on the shell instead of the heat number symbol, which had been used previously. Using a symbol for the heat number saves a lot of stamping as a heat number may contain five or six figures whereas a symbol containing not more than two figures can just as easily be used. A careful exterior examination of the material was again made and all doubtful lines filed to see their extent. The work mark was placed under the series letter on the nose of the shell. It should be noted here that it is not safe to let the shells get below the mean diameter, as it is frequently found that they will turn out light weight.

Rough and Finish Boring

Rough boring the hole constituted the ninth operation, the work being gauged with a low diameter plunger and a high diameter plug; the former being marked to check the depth of the rough bore. A percentage of the shells were tested for concentricity, and a watch kept on the chucks to see that they ran true. The bore was also examined to see that it was reasonably smooth. The work was marked on the left side of the series letter on the nose.



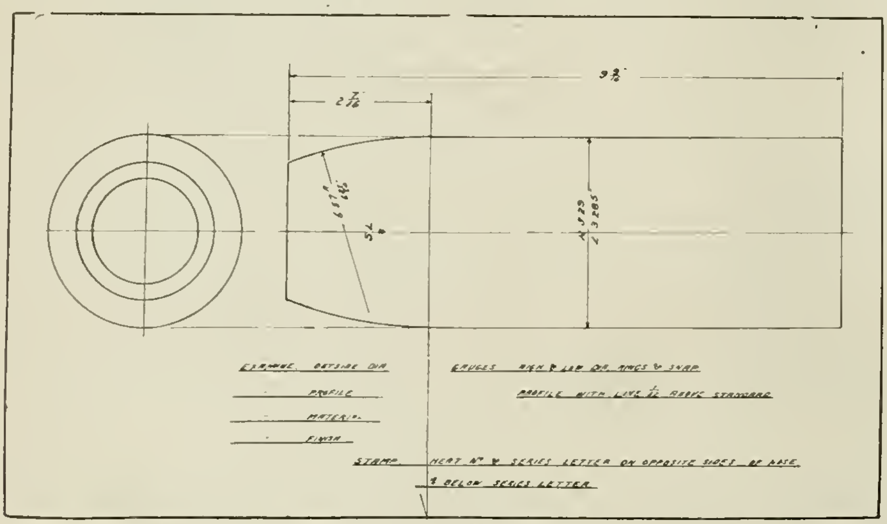
NINTH OPERATION—ROUGH BORING.

The inspection of the inside finish operation requires great care, and, from this operation on to the completion of the shell, the shop inspection requires to be very carefully carried out. Gauging the finish on the bore is not possible, the only safe way is to insist that the finish be kept up to a high standard. The shells were here examined for size and depth of hole with a plunger, and, as all shells were to standard length, all holes and base thicknesses should be the same. The walls were examined for thickness and concentricity with a wall caliper. The wall caliper is a rather difficult gauge to use until one is accustomed to it. It is preferable, however, except for getting the exact thickness of the walls in parts of an inch, to the heavy micrometer. The Wall caliper with the multiplying pointer which is sometimes used for this work is good; but it is very slow.

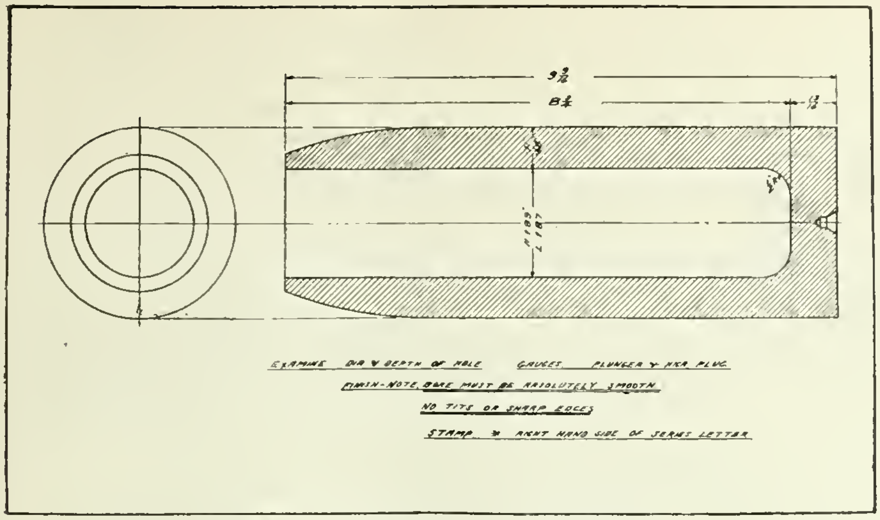
If the shells have been centred reasonably true with the drilled hole, little trouble will be run into from eccentricity. Checking up on the centring device is therefore a better method of curing eccentric shells than all the fancy gauges for detecting them after they are made. The low end of the dumbell gauge was used to see that the pocketing at the bottom of the hole was not excessive. The correctness of the inside finish operation was certified to by locating the stamp at the right hand side of the series letter on the nose.

Forming Nose Interior

The eleventh operation consisted of forming the nose of the shell. To test the concentricity of the part to be threaded with the cavity, a plunger was used. This plunger was marked, and gave an additional check on the depth of the hole; a high diameter plug was also tried in the nose. The angle of the fuse seat was checked with a small plate gauge made to the correct angle. Too much reliance should not be placed on this gauge, the best test to make is to send an occasional shell along to the thread miller and test the seat with the screw gauge. The high and low diameter of the recess on the outside was



EIGHTH OPERATION—PROFILE AND OUTSIDE BODY FINISH.



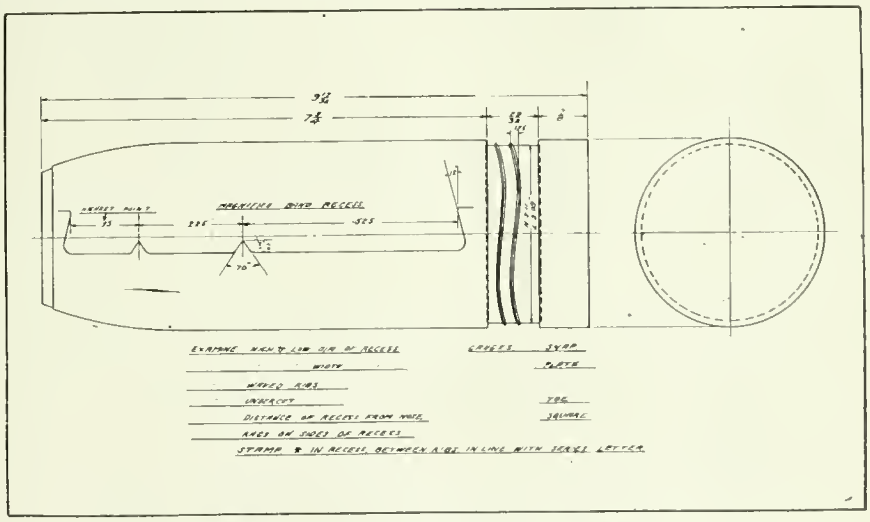
TENTH OPERATION—FINISH BORING.

gauged with a plate gauge drawn across the nose. The profile gauge was also tried on the shell to see that the line on it corresponded with the nose. The distance from the nose to the fuse hole undercut, both high and low, was checked and the undercut examined to see that it was large enough in diameter and free from sharp corners. Watching the diameter of the undercut is well worth while, if it is too small, it will surely cause trouble later on when the screw gauge is used. The distance to the undercut is very important. If it is too far down the shell it is a difficult rectification to make, and if it is even a very small amount too high up, the screw gauge will not seat; correcting this error may result in getting the undercut too wide. Just why this undercut could not be put, say 1-16 ins. further down, is not apparent; if it could, a lot of trouble and misery would be avoided. The mark for the correctness of the nose was made above the series letter on the nose.

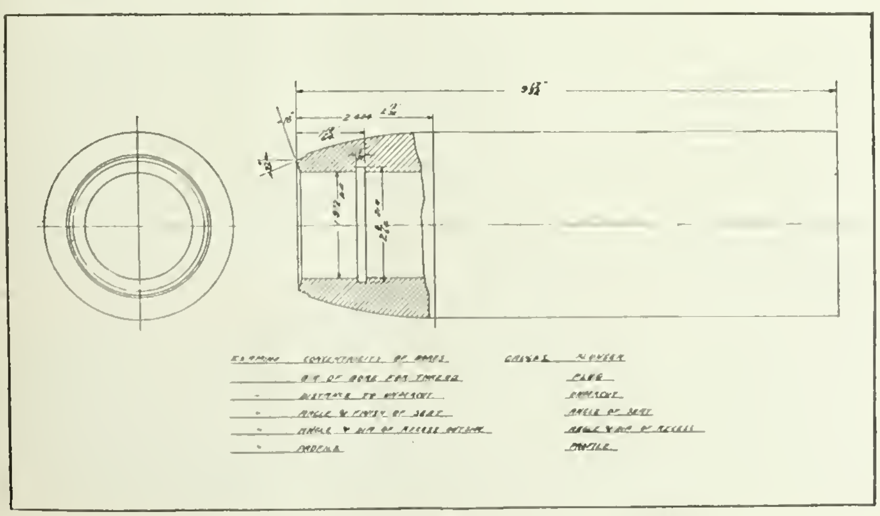
Band and Base Recessing

Putting in the band recess came next in order. The location of the recess was checked with a gauge made like a try square. The short leg lay across the nose while the long leg extended down the side of the shell, having a mark on it which corresponded with the upper edge of the recess. The diameter, high and low of the recess, was tested with a snap gauge. The size of the ribs and the undercut can be examined with the eye; but it is advisable to use the gauges on these parts frequently in order to catch a gradual change which would deceive one if the eye were depended on alone. The recess was examined to see that it was cleanly cut, the ribs not torn, and that the rags were removed from its edges. A plate gauge was used for the width of the recess. The correctness of this operation was certified to by a work mark located in the recess between the ribs and in line with the series letter. There are two reasons for locating the shop inspection marks around the series letter. One is that the heat number is already appropriated by the higher ups, while the other is that it forces the inspector to look at the series letter, and a stray shell will be detected.

The thirteenth operation, forming the base recess, is one that will repay watching if rectifications are to be kept down. The thickness left in the base of the shell was examined by putting the shell on a pillar gauge, no limits were allowed as it was endeavoured to hold a constant thickness. The flatness and smoothness of the recess were examined with a straight edge. A 2 ins. scale may be used for this work; but it is difficult to handle as the fingers obstruct the light. A better appliance is a straight edge deep enough to hold easily. The diameter of the part to be threaded and also the counterbore were examined with plug gauges. The height from the bottom of the recess to the top of the thread was also checked. If, on account of wear on the tools, this distance was allowed to get too high, threads would begin to show up when the base of the shell was faced off to weight. Following the example of the Government Examiners, the work was marked in the base near the side.



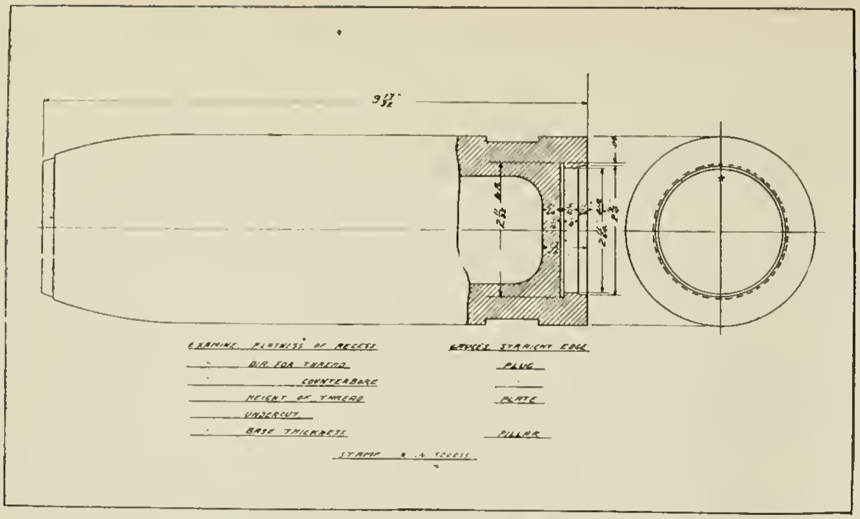
TWELFTH OPERATION—BAND RECESS.



ELEVENTH OPERATION—FORMING NOSE INTERIOR.

Nose and Base Threading

After the fuse hole was threaded, the screw gauge was used to see that it was sized correctly and that the thread was true with the seat. The high diameter plug was also tried in the thread. This plug is a big improvement over the high screw gauge formerly used in that it allows more latitude for setting the tap and yet it catches nearly all the defec-

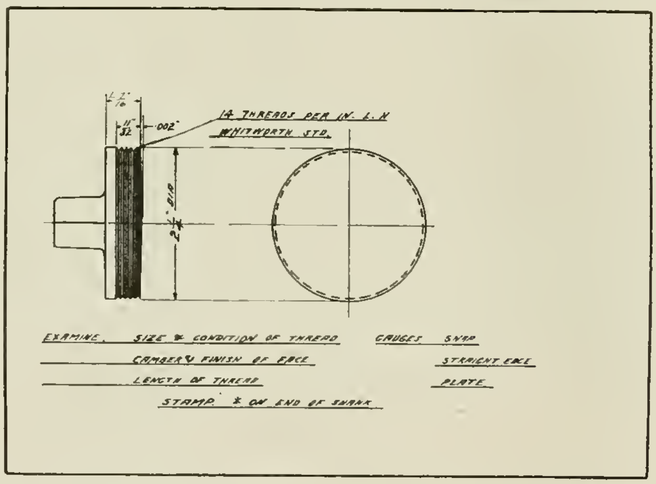


THIRTEENTH OPERATION—BASE RECESS.

tive threads. The thread was examined to see that it was all there, and that the shoulder below the undercut had not been damaged by the hand sizing tap. The correctness of the fuse hole was certified to by a work mark placed on the side of the shell in line with the series letter.

Base tapping was an operation which was not gauged, as solid taps were used. The threads were examined, and care taken to see that the bottom of the base recess had not been damaged by chips getting under the end of the tap.

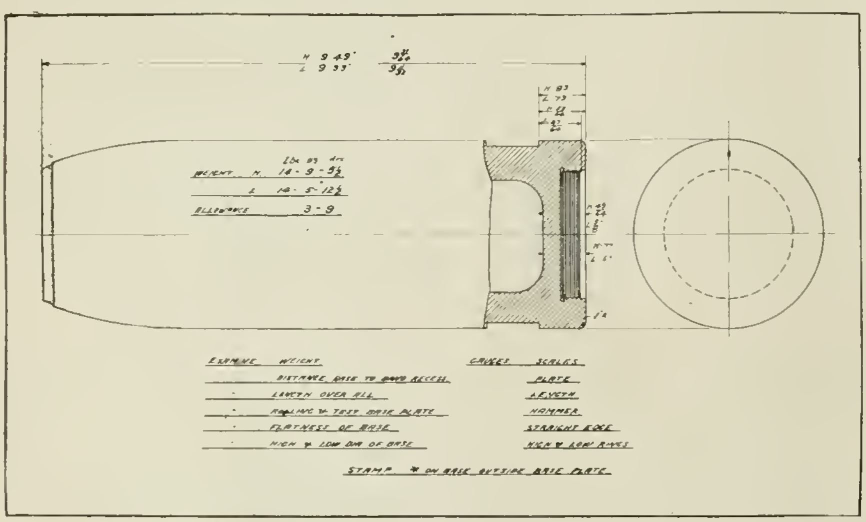
The shells were next thoroughly cleaned, and, before being passed into the inspection room, were subjected to a final shop inspection. It was not found necessary to go over the shells here with all the gauges, the more important points, however, were carefully covered, and of course any item which was known to have been slipped up on the line was specially looked out for at this stage.



FIFTEENTH OPERATION—MACHINING BASE PLATES

Base Plate Finishing

Machining the base plates is also a preliminary operation and should be mentioned. The base plates were examined with a snap gauge for diameter over the threads. The length of the thread was gauged with a small plate gauge, while the camber on the face was examined with a gauge having a step of .004 ins. on one side of it. When laid on the face, this gauge should touch across one half of the diameter, and the step should touch at the circumference directly opposite, thus giving the required camber of .002 ins. The threads were tested by trying a few base plates in sizing die, which was kept adjusted to suit the solid tap used on the base recess. The finish on the face and the material were also examined. The base plates were marked on the end of the square shank.



FOURTEENTH OPERATION—FACE-OFF BASE TO WEIGHT.

AN AMERICAN CONFESSION

IN the early days of the great war says the *Scientific American*, "the American public was dazzled and astounded by the public reports of the contracts for enormous quantities of munitions, at unheard-of prices that were being placed with our manufacturers by the European Allies, and it was regarded as quite natural and fitting that European countries, in their condition of unpreparedness, and dire necessity, should turn to America, with its reputation for mechanical ingenuity and ability, and its great factories, for assistance. American manufacturing organization and ability was to be pitted against that of Germany, and the result was contemplated with complacency. American energy and efficiency was to show its superiority over the supposedly sterotyped routine of continental shops; but the actual results have been a humiliating surprise, in many instances, both to the public and to many an optimistic contractor... ..One of the worst features of our failure to make good in the production of arms and ammunition of a satisfactory quality is the loss of prestige that American manufacturers will suffer after the war is over, when trade will be needed to keep all of our new mushroom plants going.....The trouble with our manufacturers does not lie in the character of our machinery, nor in the ability of American workmen, for we have as skilful mechanics as any other country, but rather in matters of organization and superintendence. Then, again, there is a fatal tendency among many of our shops, when taking up a new product, to start in without a thorough understanding of the requirements, and to jump at conclusions. Another habit is to attempt to tell the buyer what he ought to have instead of giving him what he wants."

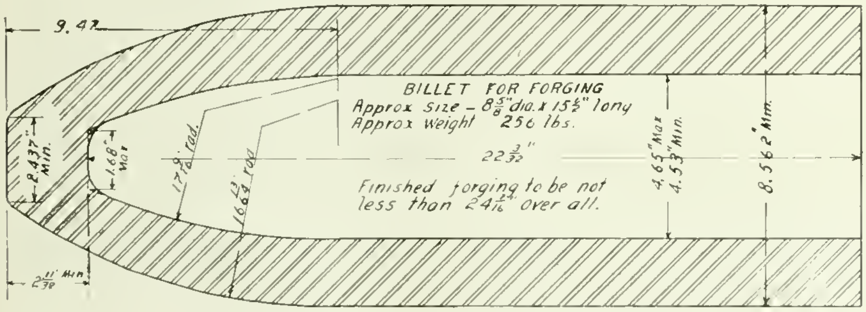
Vancouver, B.C.—The establishment of a smelter on the coast of British Columbia with a measure of Government assistance was foreshadowed in a speech read by Lieut.-Governor Barnard on the occasion of the opening of the Provincial Legislature on March 1.

Female Labor on 8 ins. High Explosive Shell Machining

Staff Article

Although not engaged in the production of the largest and heaviest shell being furnished by Canadian metal-working establishments, the plant from which the accompanying article was derived is engaged in the machining of that next in order in the matters of type, size and weight. An added interest may, however, be aroused when cognizance is taken of the excellence of the facilities provided for reducing to a minimum the labor of handling such heavy pieces as 8-inch high explosive shell bodies and adapters by women operators.

IT IS more than probable that when events enable an impartial review to be made of the history of munitions making in Canada, the entry of female help, as an active factor in production, will be given a prominent place, not only on account of the novelty of the situation, but because of the stimulating effect it has had in developing machine shop methods, devices, and conditions. Women and girls accustomed to office, warehouse, and light factory work are now employed successfully on all sizes of shells, although the largest and smallest offer the best proposition, the former because installations of labor-saving devices which were desirable, even with men operators—were with suitable refinements, readily adaptable to operation by women, while 12 and 18 pdr. shells could be handled readily without special apparatus.



APPROXIMATE FORGING SIZES OF 8-INCH HOWITZER SHELL.

Women Workers

The executives of the plant described in this article were amongst the first to reach a decision on the matter, and the entire work of machining, assembling, and inspecting 8 in. shells and adapters is accomplished by female help with one or two exceptions, which will be noted in due course.

It was assumed at the outset that mechanical ability should not be expected from the great majority of the help, and for this reason the operations were so simplified that any worker of average intelligence could quickly understand the work, while, on the other hand, the machines were designed and built on a system which not only gave them a high degree of "foolproofness," but insured a surprisingly high output of accurate work.

LIST OF OPERATIONS.

Body.

- Rough drill nose.
- Rough turn body.
- Rough turn profile.
- Cut off base and nose.
- Rough bore body.
- Rough bore profile.
- Finish ream interior.
- Second rough turn body.
- Finish turn body.
- Second rough turn profile.
- Finish turn profile.

Base.

- Rough counterbore and face.
- Finish ream counterbox.
- Finish ream.
- Rough tap base.
- Finish tap base.

General.

- Finish and tap nose.
- Fit and drive adapter.
- Roll adapter joint.
- Rough face and weigh.
- Groove and weigh.
- Press on copper band.
- Finish turn copper band.
- Cut off square.
- Finish face, etc.
- Government inspection.
- Varnish, paint and ship.

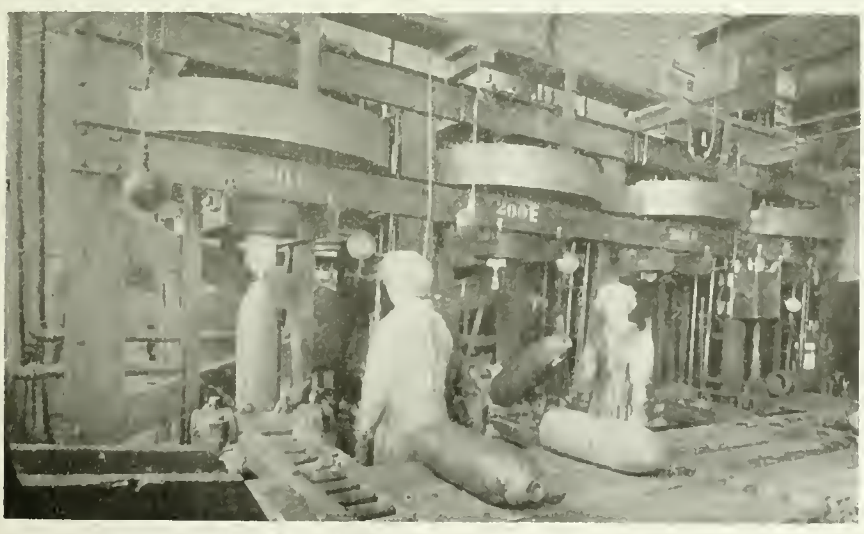
The subdivision of the work resulted in about twenty-five separate handlings. While large, however, the time and labor involved is probably less, all told, than would be the case in a shop employing skilled mechanics and using standard types of machines which do a maximum number of operations at one setting. This result was accomplished by installing conveyor tracks of a suitable type and on such a liberal scale that no machine operator is required to exert more than a ten or twelve pound effort in any direction either while chucking the work or operating the machine. Lifting of the shells by unaided physical effort is entirely tabooed.

Type of Equipment

A satisfactory system of handling having been decided upon, the problem of machines remained, and the manner in which this has been tackled and solved constitutes, in the opinion of many, a unique instance of mechanical genius, daring and accomplishment. Tradition has been rudely jarred in many other fields in the last three years, but in none more than the machine shop.

Quantity production in gasoline engine manufacture had previously laid good groundwork on which present developments were built, but even the most sanguine of engine builders never dreamed of doing work of similar weight and accuracy at anything like the speed obtaining in this plant.

Out of the twenty-odd operations referred to, about sixteen are done on machines which, except for the gearing between belt and spindle are operated entirely by hydraulic power. Many of these are standard heavy duty 26-in. lathes, stripped of feed gears, shafts, etc., and fitted with hydraulic cylinders which operate the carriage travel, tailstock, spindle, chuck, or driver for work, and in the case of driving the adapters, torsion is directly applied through a hydraulically operated ratchet lever.



DRILLING SHELL NOSES IN A FOUR-SPINDLE MACHINE WITH INDIVIDUAL MOTOR DRIVES AND HYDRAULIC FEEDS AND HANDLING GEAR.

The foregoing table of operations gives an approximate idea of the system, and in conjunction with the photographs and line drawings will, it is hoped, convey to the reader, a clear idea of the principal features of the system.

Hydraulic Control

The method of operating the hydraulic cylinders might be termed constant pressure with controlled exhaust; that is to say, the total pressure on either side of a piston is constant and by letting the fluid on the other side escape more or less rapidly, the speed of the piston, and consequently the rate of feed of the cutting tool is increased or decreased. In order to get consistent results with this system it is necessary to have sufficient pressure on the piston to insure its movement being entirely dependent on the escape of the exhaust. Thus, if a heavy side were alternating with a light side, the tool must be fed under the heavy cut with the same speed as on the light, so that the maximum cut which the machine will take is a factor in deciding the amount of power required in any one cylinder.

A careful investigation of these points resulted in a pressure of from 55 to 70 lbs. per sq. in. being adopted as most suitable, taking into account the available spaces in which cylinders had to

FIG. 1. GAUGE FOR TESTING CONCENTRICITY OF DRILLED NOSE WITH ROUGH BORE.

be placed with a consequent limit to their diameter. While no definite data are available as yet, the fact that patent rights have been applied for, indicates that results have fully met anticipations and the commercial development of the system is a probability of the future.

Reviewing the work in a progressive manner, reference may be made to the receiving of the forgings which are discharged directly from the railroad car onto an elevating conveyor which passes the forgings through a small, coal fired furnace for taking the chill off the material during cold weather, avoiding loss of time or undue discomfort in handling them a few minutes later in the shop.

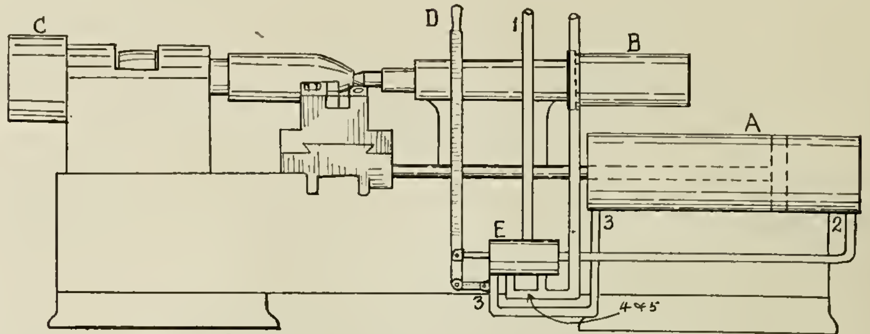


FIG. 2. DIAGRAM OF LATHE, SHOWING PRINCIPLES OF HYDRAULIC FEED CONTROL.

A Unique Drilling Machine

The forgings enter the building at a steady rate of one every so many seconds, according to requirements, the entrance being through an opening in the wall behind the four-spindle nose-drilling machine, illustrated on page 207 The opening is level with the platform shown in the foreground, and the forging travels with very little effort on the roller runway till it is abreast of the platform when it is rolled along by men helpers to the particular spindle in which it is to be drilled. This drilling machine is an outstanding example of the originality of equipment throughout the shop and by means of two valves the operator controls the work from the instant when it is pushed along the track onto the supporting arbor, the tilting of the arbor from a horizontal to a vertical position being done by hydraulic power also. The spindle of the machine is a square sliding shaft driven by a large pulley with belt drive over guide pulleys to individual motors on the floor, back of the machine. As will be observed from the illustration, the four machines are built as a unit, the framework being of heavy channel sections with two platforms on the upper part, one carrying the driving pulleys and the other carrying the hydraulic feed cylinders.

The tilting arbor is controlled by a four-way valve which is referred to

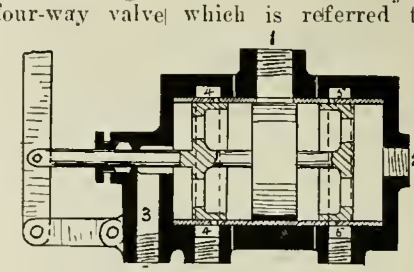

FIG. 3. SECTION OF HYDRAULIC CONTROL VALVE.

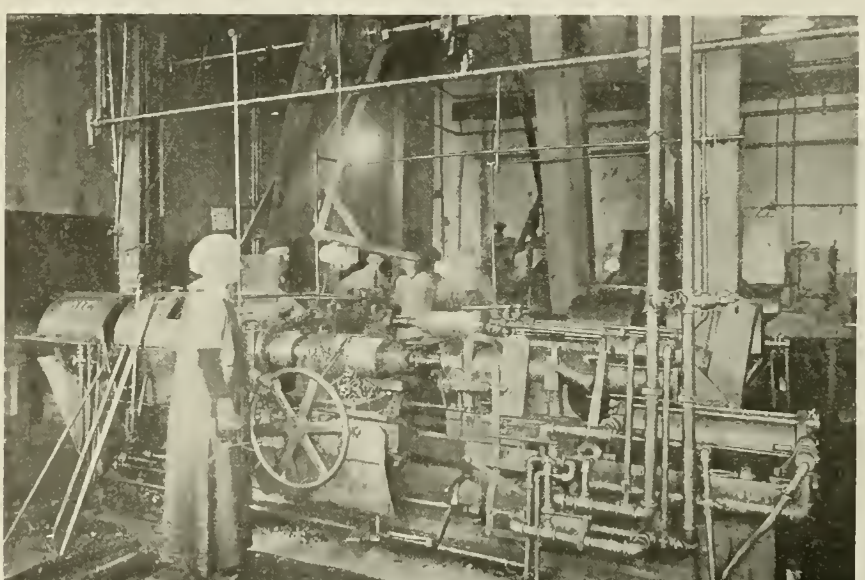
subsequently. No preliminary centering is done, as the drill used is merely long enough to provide for a reasonable amount of grinding and is socketed directly into the end of the square spindle, giving ample rigidity when starting the hole on uneven surfaces.

The drilled forging is tested with a gauge, as shown in line drawing, Fig. 1, which checks the concentricity of the hole with the internal surfaces, after which the forging is sent along one of several runways which extend along the shop, and has only a few feet to travel when it reaches the rough turning lathes.

The machines for each successive operation are arranged transversely across the length of the shop so that several streams of shells are proceeding parallel with each other through the various zones of operation until the primary lathe work is accomplished and the shell is ready for the group operations connected with the base, nose, and band.

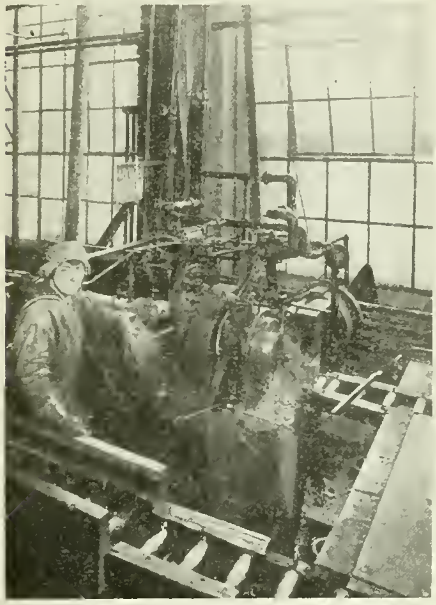
A Lathe Without Feed Gears

On this page is reproduced a view of a hydraulic lathe on the rough turning operation. This is a standard 26-in. heavy duty lathe which was formerly built in considerable quantities by this firm for other concerns as well as for its own use. Those in use here are all hydraulically operated, the line drawings, Figs. 2 and 3, showing diagramatically the method of operation. All feed gears and shafts, carriage apron, and tailstock hand-wheel have been re-



ROUGHING 8-IN. SHELLS ON LATHE EQUIPPED WITH HYDRAULIC FEED TO SADDLE, HYDRAULIC CHUCK AND TAILSTOCK SPINDLE.

moved. At the end of the bed cylinder A rests between the shears and is connected to the carriage by a piston rod which extends through below the tailstock casting. On the rear end of the tailstock casting a small cylinder, B, is



DOUBLE-END CUTTING-OFF MACHINE WITH HYDRAULIC FEEDS AND EJECTOR.

mounted for actuating the tailstock spindle, while on the rear end of the headstock a large diameter cylinder, C, is mounted, which actuates the draw bar through the spindle to tighten the self-centering expanding driver which grips the forging on the inside. Lever D operates the control valve E connected with cylinder A, and by moving this lever more or less in the desired direction, the piston in the cylinder and also the lathe carriage is moved accordingly.

Simplified Control

As seen in the engraving the control for the three cylinders has been well centralized. A four-way valve on top of the tailstock controls cylinder B. Another four-way valve just above the shears, in front of lever D controls the driver, lever D itself being placed within easy reach, but not so as to interfere with the operator's movements. Contrary to expectation, the piping is comparatively simple in arrangement, although the improvised nature of the various devices imparts a somewhat complex appearance to the apparatus.

The controlling valve E, Fig. 3, is numbered to correspond with Fig. 2; it is shown in midposition. Pressure inlet 1 is closed, as are also the exhaust ports into outlet passages 4 and 5. Connections 2 and 3 go one to each end of cylinder A. When lever D is moved to the left, the solid central piston allows pressure to pass to the right through the perforated piston into passage 2 and thence to the right end of cylinder A. No movement can take place, however, until the other perforated piston uncovers exhaust ports into space 4, allowing liquid from the left end of cylinder A to escape through passages 3 and 4. By suitable arrangement of holes in valve E the exhaust can be regulated to a nicety resulting in an ideally smooth uniform and powerful movement of the lathe carriage in either direction and at any speed, variable while the tool is cutting.

Handling the Forging

The handling devices are very simple and obvious, though not in general use. Each conveyor track is laid between two rows of machines which are loaded from the back. Reference to the illustration will show a supporting frame between the shell and the carriage. This is a hinged portion on the end of a branch from the main track. When placing a shell in the lathe, the operator has it rolled toward her by a helper who serves a group of machines. Arrived on the frame, she presses a pedal with right foot just below carriage, thus raising the shell level with the spindle. The shell rests on rollers carried by the frame and little effort is necessary to slip it over the driver. Still holding the pedal down, she opens the tailstock valve which causes the tail centre to advance against the hole in the nose with a certain definite pressure, after which the tailstock spindle is locked in position and machining commenced.

Use of Stellite

The cutting metal used in this and all the other turning operations is Stellite. The various grades of this metal now obtainable enable a wide variety of requirements to be met. As used in the majority of the machines in this plant, stellite is in the form of 1 in. square bars supported in solid tool boxes with no overhang, and clamped along their full length to within a very short distance of the point. For reasons of comfort and safety, a copious supply of lubricant is used, although a cutting speed of 55 ft. per min with 1/4 in. feed and 1/2 in. in depth of cut, results in chips which are uncomfortably hot in spite of the lubricant. The length of the parallel portion rough turned at this time is approximately 14 in., and on occasion a stellite tool has rough turned 60 forgings without grinding, average performances being well over 50 forgings. When it is considered that the former figure is equivalent to 840 feet of 8 in. shafting, while the tool passes over a surface exceeding 1¼ miles in length, the wonderful nature of this alloy is more readily comprehended.

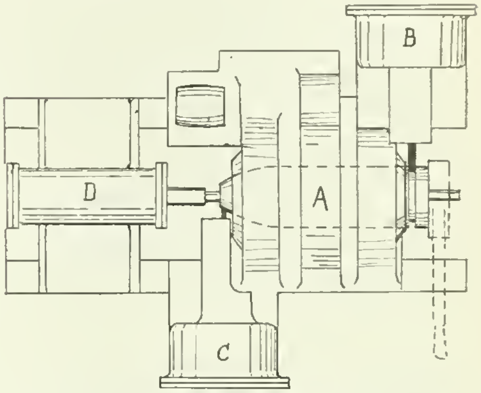


FIG. 4. PLAN OF CUTTING-OFF MACHINE SHOWING FEED AND EJECTOR CYLINDERS.

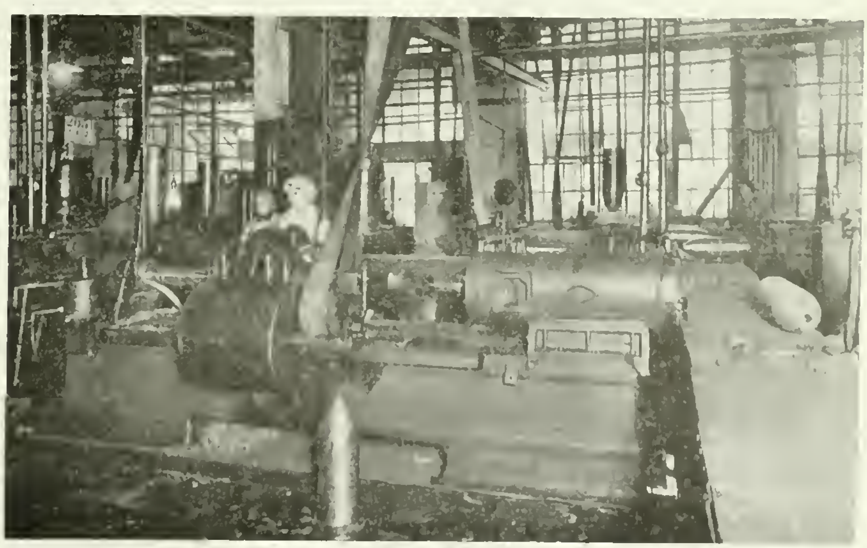
The nose profile is now rough turned in a 26-in. lathe of the type used for the body diameter, thus completing those operations in which the heaviest work is done.

Double End Cutting-off

The operation of cutting-off the base and nose is performed simultaneously in a specially constructed machine. In the course of certain experiments the engineering department evolved a driving head in which the shell is held inside of the driving spindle so that both ends can be operated on simultaneously. The experiments were not completed but several of the machine parts were found adaptable in a number of instances such as this, so that the entire equipment possesses a degree of individuality found in few, if any, other shops engaged in munitions.

Line drawing Fig. 4 is a plan view of this machine, A being the driving head.



VIEW OF BORING MACHINE SHOWING HYDRAULIC FEED CYLINDER, DRIVING HEAD AND CLAMPING FIXTURE.

B the base cylinder, C the nose cylinder and D the chucking cylinder. These four units are securely bolted to a couple of 18 in. x 6 in. I beams and com-

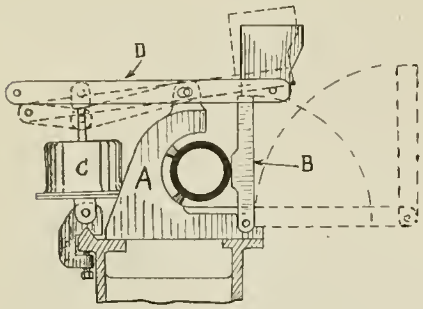


FIG. 5. HYDRAULIC CLAMPING FIXTURE FOR SHELLS.

plete the operation on both ends in 4 min. 8 sec. The exterior of the shell nose being rough turned, the interior of chuck is curved to fit it. The piston rod of chucking cylinder D extends through the shell during the operation and by means of a detachable cross bar, is employed to draw the shell tightly into the curved end and hold it there while chuck jaws are tightened on the base end. On completion of the cut, the chucking cylinder D forces the shell out onto a short runway (see illustration on page 209 from where it is rolled back

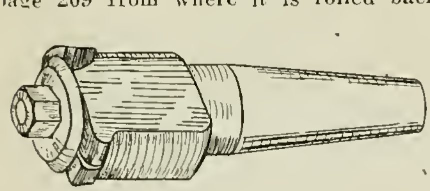

FIG. 6. THREE CUTTER BORING HEAD FOR ROUGH BORING FORGINGS.

into the main conveyor to proceed to the boring machines.

The disposition of the metal in the forging, diametrically, has therefore been determined from the bore, starting with the drilling operation where the forging was centered on an arbor so that the hole in the nose was concentric with the bore of the forging, subsequent rough turning removing any eccentricity in the walls, while the shell as now delivered to the boring machines has a machined diameter for chucking by, and a machined surface at the nose end which is now the starting point for locating lengthwise dimensions.

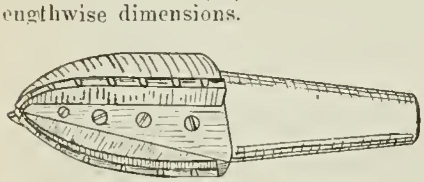

FIG. 7. ACORN TYPE OF HEAD FOR MACHINING INTERIOR PROFILE OF NOSE.

Boring Operations

The work of machining the interior is divided into three groups of operations, boring, base finishing and nose finishing. The boring operations are three in number, rough bore straight, rough bore nose and finish ream; identical machines are used in each operation, with suitable cutter heads for each.

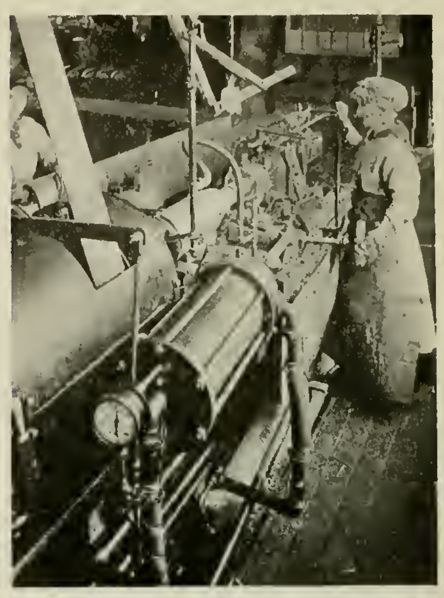
One of these machines is illustrated on page 209. The main casting will be recognized as a lathe bed, the driving head is the same unit as used on the cutting-off machine, the hydraulic feed cylinder at the right was cast from the pattern of a gas engine cylinder, while the shell is chucked by a hydraulic clamp in the fixture at the other end of the bed. The illustration also shows one of the transverse platforms connecting the main runways, one of which passes behind the machine illustrated. From this runway a short hinged gangway enables the shells to be rolled straight into the fixture, which consists of a horizontal open-sided gap casting A; see line drawing, Fig. 5. The shell is centered on three point contact, two of which are inserted hardened steel blocks supporting the shell at either end of the straight machined portion, while clamp bar B is tightened against the opposite side. Meanwhile the machined end of the nose has been placed in contact with the end of casting A, which locates it positively in relation to the feed bar stops, and also allows the use of a copious stream of lubricant applied at the proper place. A simple arrangement of toggle gear is combined with hydraulic cylinder C. When the fixture is open, the piston is drawn down, contracting the toggle and raising the opposite end of links D, while bar B occupies a horizontal position as shown by dotted lines. When clamped tight, the parts occupy the positions shown by the full lines, the only effort required of the operator being that necessary to swing clamp B up into position.

The driving head which occupies the centre of the machine is provided with a long square hole through the centre in which the square boring spindle is a very accurate fit. This square hole is of sufficient length to maintain the spindle in accurate alignment with the centre of the shell as held in the chuck, and continuous operation 24 hours per day and 7 days per week, has failed to reveal any weakness in several months' operation. The piston rod is coupled to the square spindle through the medium of a thrust bearing and in the case of rough boring, it feeds the tool at 1/4 in. per revolution. It is able to do so because of the three cutter tool used, which reduces the work of each cutter and produces a reasonably smooth surface which can be afterwards reamed at one pass. Line drawing, Fig. 6, indicates the type of cutter referred to. The portion bored is approximately 14 in. long and occupies 2 min. 5 sec. of actual cutting time.

Nose Boring Tools

The tools used in boring and finishing the nose interior are of similar design with three inserted teeth. The rougher is notched as shown in line drawing Fig. 7, while the finisher is carefully sized all over so as to finish both the parallel portion and the nose. Considerable care is exercised in the latter operation to insure a smooth finish, thus extending the time to 4 min. 10 sec.

In all of these boring machines, posi-



FINISHING PROFILE OF SHELL NOSE. THE CYLINDER IN THE FOREGROUND OPERATES THE RADIAL TOOL-BOX.

tive stops are provided on the end of the square spindle next feed cylinder. These make contact with the end of the square hole driving sleeve, dispensing with any gauging on the part of the operator.

Maintaining Accuracy

In spite of the close limits which are held in these roughing operations, the rough drilled hole in the nose may now be slightly eccentric with the finished bore, and this inaccuracy is removed by holding the shell on a formed

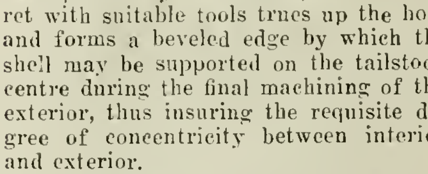


FIG. 8. ARRANGEMENT OF ROUGHING CUTTER BAR FOR RECESSING BASE.

arbor mounted in the special geared head previously referred to, while a turret with suitable tools trues up the hole and forms a beveled edge by which the shell may be supported on the tailstock centre during the final machining of the exterior, thus insuring the requisite degree of concentricity between interior and exterior.

These operations consist of two finishing cuts on the body and the same on

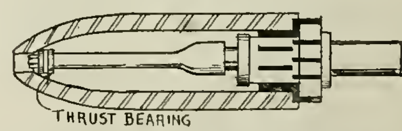

FIG. 9. TWO DIAMETER REAMER FINISHING BASE. THRUST BEARING ACTS AS FEED STOP.

the profile. The first finishing cut brings the body diameter to nearly size, and also reduces the base diameter up to where the band groove is cut; the second cut is the final and brings the body diameter within the required limits. Similar procedure on the nose profile completes what might be termed operations of the first magnitude, which impart the basic accuracy to the product.

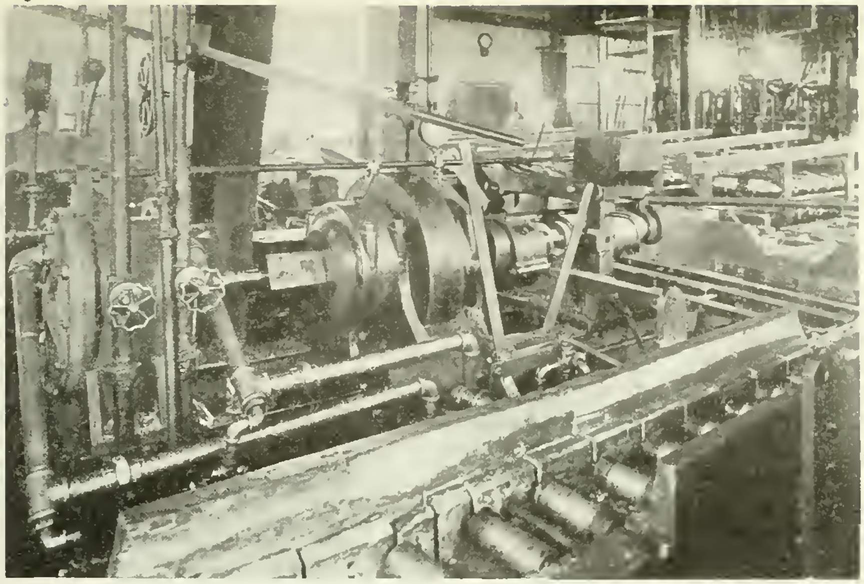
Profiling Lathes

Profile-turning on the nose is the concluding operation of the primary group. Both in the roughing and finishing operations the thickness of metal is determined positively by the use of a sleeve, one end of which fits against the finished interior surface of the nose, while the other is positioned against the end of the driver in the lathe spindle. The only movement of the tool, therefore, is radial, passing around the curve of the nose, and this allows the use of a fixed carriage, leaving the depth of cut as the only adjustment over which the operator has control. See page 210.

Radial movement is imparted to the tool block by the cylinder shown in foreground, which is pivotally mounted on the carriage, so that when the piston is full back, the radial link is at right angles to the shell.

All that the operator has to do in the way of tooling is to feed forward till the tool is touching the shell, and then push over the control lever located at her right, the distance through which the lever is moved governing the rate of feed. Because of the pivoting of the cylinder, flexible pipe connections are necessary. Hydraulically operated drivers and tailstock spindles are fitted on all of these lathes.

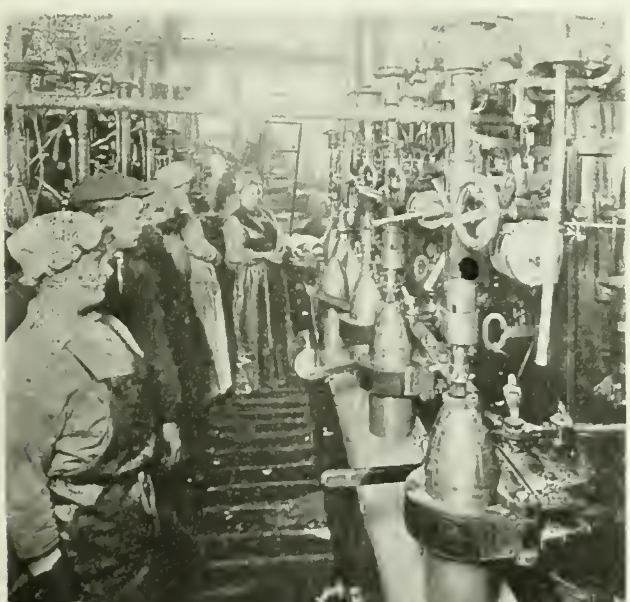
This operation is an instance of the wide range of application of Stellite. With a feed of ⅛ in. per rev. and a light finishing cut, the finished surface is all that can be desired. The cutting speed starts at over 200 ft. per min. on the body and gradually decreases as the point of the nose is reached, the net time being 1 min. 24 sec. All of these lathes are fitted with foot operated platforms under the shell, which enable the operator to set up and remove the work single-handed with slight effort and very little time. The lever extending from the top of the headstock is part of a foot-brake with which every machine throughout the factory is fitted. It is pedal operated, the foot lever being held down by a detent so that the machine cannot be started inadvertently until the operator is prepared.



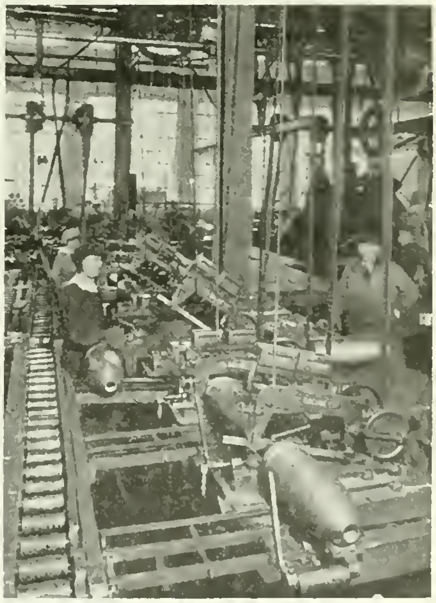
ADAPTER DRIVING MACHINE WITH HYDRAULIC RATCHET FOR FINAL TIGHTENING OF ADAPTERS IN PLACE.

Base Operations

This work is divided amongst three groups of machines in the following manner:—1st, rough out the counterbore and face the end to a certain high limit; 2nd, ream the counterbore and portion of bore which is to be threaded; 3rd, tap the thread to fit adapter. The first two operations are performed in boring machines identical in construction with that used for the boring work already described. The cutter heads used are of conventional design, with inserted cutters set for the required diameters. A special cutter is provided which chamfers the edge of the counterbore just ahead of the boring cutters; this is done to prevent the forming of a ragged edge, which would interfere with the removal of pilot bushings for guiding the boring head during this operation. The arrangement of these bars is shown diagrammatically in line drawings, Figs. 8 and 9. In Fig. 9 the smaller set of cutters ream out the body to tapping size, while the larger set ream the diameter of the counterbore and face the bottom of it to fit properly against the flange of the adapter.



BEVELING, REAMING, RECESSING AND TAPPING NOSES IN VERTICAL DRILLING MACHINES.



CUTTING SQUARES OFF ADAPTERS IN BATTERY OF HACK SAWS WITH COMPLETE SYSTEM OF CONVEYOR RUNWAYS.

Threading the base is done with Victor collapsible taps and Colburn heavy duty drilling machines. It is divided into roughing and finishing, the tap which does the roughing being fitted with a ball-bearing keyway, which eliminates all driving friction, allowing the tap to enter freely and form a perfect thread without any chance of stripping with unskilled help. The second tap is more of a reamer, and is arranged to take just enough of a cut to insure a good surface on the thread. Both taps operate at the same speed, viz., 40 sec. per shell.

All of these drills are fitted with tilting chucks into which the shell is slipped when in a horizontal position, runway rollers being laid in position at each chuck.

Nose Operations

Four separate operations are required to finish the nose, viz., bevel, recess, ream and tap. The tapping is divided into three stages. Six 12 in. Barnes vertical drills are used, each of which does only one part of the work. They are arranged in a row, forming a six-spindle gang drill, and the shells travel past each spindle in succession, being operated on in the order mentioned above. A view of these drills is reproduced on page 211, the three nearest having Murchey collapsible taps with floating drive from the machine spindles. The special chucks fitted to these machines are also shown, the hinged strap being locked by an eccentric lever. Cutting compound is used freely, the table draining back into the shop system which is referred to later. The average time for a shell to pass through the group is just over 6 min.

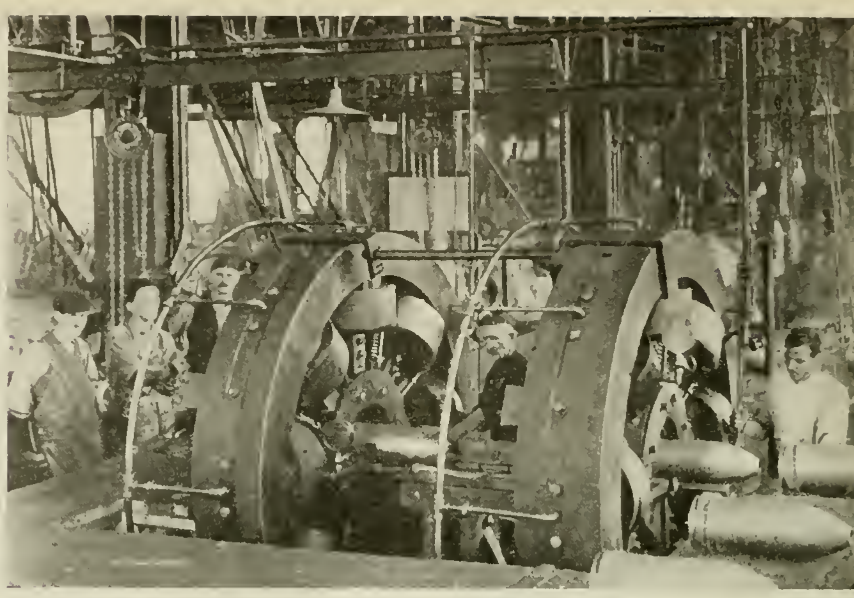
Washing, Weighing And Gauging

The shells are now placed on two live rollers and revolved at a moderate speed so that the compound and other foreign matter can be rapidly removed from both interior and exterior, blown out with an air jet, gauged and stamped, after which they are washed in lye at 150 degs. and rinsed in water at 110 degs. The tanks containing the solutions are heated by steam jets which are arranged to circulate the liquid in the interior of the shells. An endless conveyor band extends completely around the tanks dipping into each and carrying the shells in and out at a speed which gives an entire immersion of 4 minutes.

After gauging the shells are fitted individually with adapters, a number of special benches being fitted up with racks, and clamping straps which enable the selection of adapters to be rapidly performed with every assurance of the threads being a proper fit in the shell. The necessity of selecting adapters in this manner has been found more satisfactory and quicker than trying to work to very close limits on the threads themselves, as any slight wear on taps or dies, unless detected immediately, causes sufficient variation to necessitate selective fitting anyway, and by handling the problem in the manner described the output of taps and dies can be greatly increased.

Concluding Operations

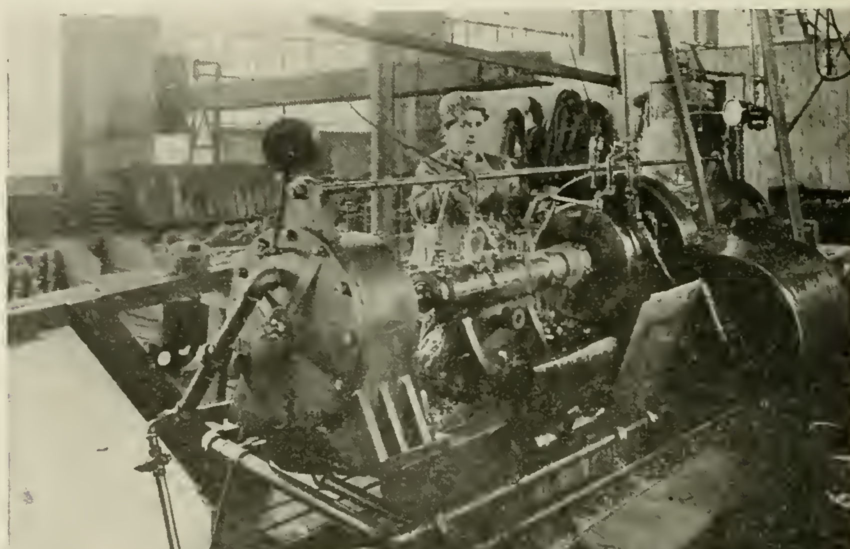
The component parts of the shell, having now reached a more or less complete state, are submitted for preliminary inspection by government inspectors, who remove the adapter, and inspect every feature of the shell for finish and accuracy, after which the concluding operations are performed. These are of a miscellaneous nature and are all performed in widely different machines. Adapter driving, centreing, rolling and facing; grooving, banding and band turning; cutting square off adapter, and facing to weight are necessary to complete the machine work, after which varnishing final inspection, and boxing are done.



HYDRAULIC BANDING PRESS ARRANGED TANDEM FASHION, WITH CONTINUOUS CONVEYOR SYSTEM.

Adapter Driving Machine

The machines used for this purpose are very similar to the boring machines, and offer still another example of the ubiquitous resourcefulness displayed by the engineering department. By comparing illustration of this machine on page 211 with that of the boring machine on page 209 it will be seen that the general outline is similar, allowing for the views being of opposite sides. A driving head in the centre carries a square spindle, a clamping fixture holds the shell at one end, and a hydraulic cylinder at the other end feeds the spindle. A square hole in the spindle end engages the square on the adapter, (just noticeable in the picture), and with power supplied by the regular belt drive the adapter is driven home till the belt slips, the feed cylinder keeping the spindle firmly engaged with the square. A ratchet device carried on the spindle end is operated by a vertical cylinder at the back of the shell fixture and of sufficient diameter to put maximum torsion on the adapter. The operator turns on the hydraulic ratchet which makes two or three bites, the entire



ROUGH TURNING ADAPTER FORGINGS IN CHUCKLESS MACHINE WITH HYDRAULIC CONTROL.

operation, including handling, being completed in less than 2 min.

The subsequent operations are performed in machines of conventional types, all of which, however, are specially tooled according to the particular work required of them.

Tandem Band Press

Considerable interest attaches to the method of using the banding presses. These are of the radial cylinder type with eight cylinders each and are arranged in horizontal tandem fashion with runway level with centre of the frames, see illustration on page 212. The use of two sets of dies was found desirable owing to the width of the band; the dies in the first machine press hardest in the centre of the band allowing the escape of all air and thus insuring proper contact on the waves, while the dies in the second machine spread the pressure out to the sides of the groove and fill the band right into the undercut.

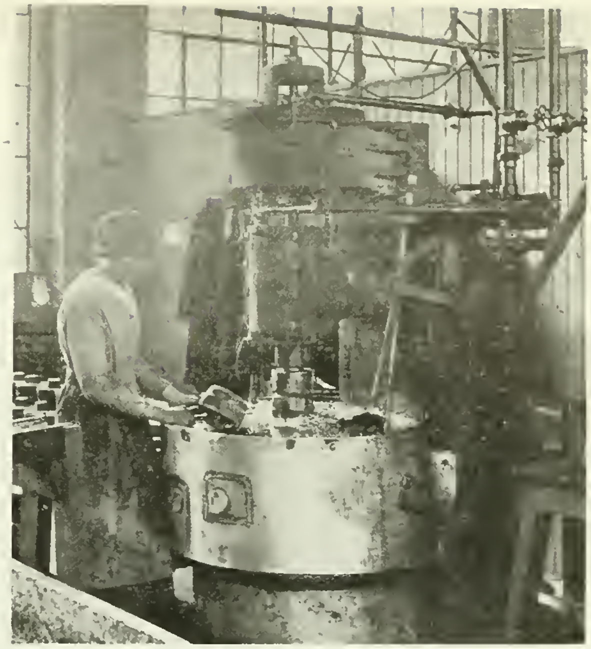
After turning the band profile the shells are handled on individual wooden cradles which travel on a runway extending along a battery of Racine hack saws, shown on page 211. The finished band overhangs the edge of the hinged rack across which the shell is rolled to the saw table. Running from each table to the platform at the back is a short length of conveyor rolls surrounded by an endless belt which travels with the shell and protects the band from damage.

Facing off the base, and adjusting the weight complete the work ready for government inspection before varnishing and painting. An air-drying varnish is used which dispenses with baking ovens. A view of the department where this final work is done is reproduced on this page the shells being under official surveillance until they are shipped direct from this department into railroad cars.

Adapter Operations

The possibilities of hydraulic control of machine tools are further illustrated by two illustrations of adapter machining which follow. The smaller of these shows the initial operation of rough facing, the machine in use having originally been a Bertram vertical turret lathe. The cross-slide mechanism has been replaced by a feed cylinder which forces down a square ram carrying a stationary head with flat cutters. The rough forging is provided with a special square on the back which is dropped into a square hole in the centre of the revolving table, no chucking of any kind being required. An indicating needle informs the operator when sufficient metal has been removed, and when control valve is reversed a knockout forces the forging up ready for removal by hand. The average output is 40 per hour.

The larger illustration shows the rough turning operation which is further explained by line drawing Fig. 10. The extemporized construction is well shown, driving head, cylinders, I beam bed, and pillow block casting forming arbor guide. The adapter is driven by a socket in the end of square bar into which the square fits. The forging is held in this position by hand with both cylinders full back. The right hand cylinder now advances the supporting arbor, thus clamping the forging firmly between the two ends as shown. By maintaining full pressure on the back of the left hand cylinder and controlling the exhaust from right hand cylinder, the forging floats across the cutting tools while being rotated by the square driving bar. The two diameters of the adapter are roughed off by Stellite tools in 1 min. 40 sec.



ROUGH FACING ADAPTER FORGINGS IN CONVERTED VERTICAL TURRET LATHE.

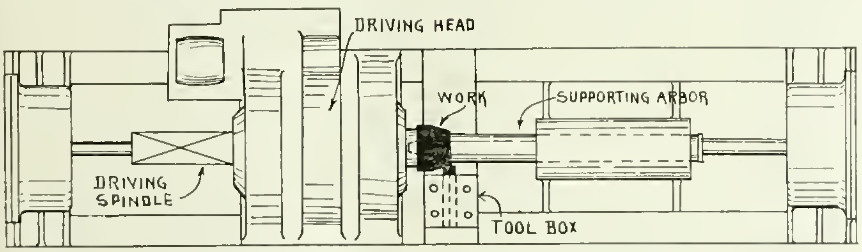


FIG. 10. PLAN OF ADAPTER ROUGHING MACHINE SHOWING METHOD OF FLOATING WORK PAST THE CUTTING TOOLS.

The subsequent operations on the adapter are completed in turret lathes, thread cutters, etc., the various toolings being of familiar types which call for no special comment.

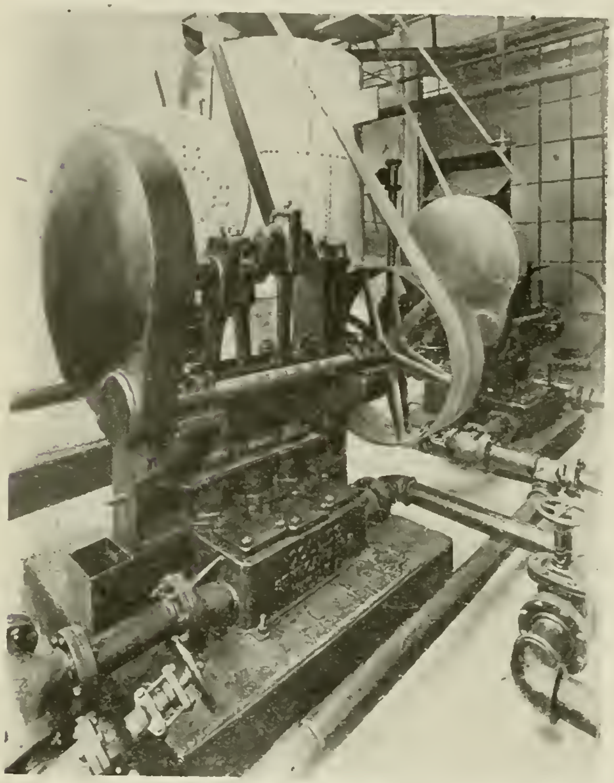
Hydraulic Power Supply

While no definite mention of the number of machines is permissible, the amount of hydraulic power required is a small percentage of the total power consumed by the machines, 7½ horsepower being sufficient to provide the necessary feeds on all of the machines. The plant consists of duplicate sets,

VIEW OF FINISHED SHELLS BEING VARNISHED, PAINTED, INSPECTED AND BOXED FOR SHIPMENT.

one being reserve. Goulds three-throw pumps, 7 in. x 7 in., driven by 30 horsepower motors. Each pump is a unit by itself, with its own receiving tank, two discarded boilers 72 in. x 12 ft. being used for this purpose.

These tanks are kept about half full with compressed air connections for providing the initial air space. The liquid used is straight cutting compound, and all leaks, bye-passes, cooling streams, etc., drain into a common return tank from which the pump suction is taken.



DUPLICATE POWER PUMPING PLANT WHICH SUPPLIES HYDRAULIC POWER FOR OPERATING THE MACHINES DESCRIBED IN THIS ARTICLE.

BRITISH SHRAPNEL MANUFACTURE IN CANADA

THE Canadian Commercial Agent at Petrograd, Russia, C. F. Just, writing to the Department of Trade and Commerce, Ottawa, says it will interest Canadian munition workers to know that a Petrograd publishing house has recently added to its series of technical publications an interesting booklet entitled, "The Manufacture of English Shrapnel in Canadian Factories." The authors, Messrs. Sdzitovesky and Bekker discuss at length how promptly and with what ingenuity the equipment of Canadian works was adopted to the production of munitions, and, incidentally also, the resources, incentiveness and the enthusiasm displayed by the workers in tackling and solving the difficulties of manufacture altogether new to their experience. The book is very fully illustrated with cuts and detailed drawings of the tools, and of specially designed tool parts employed, accompanied by explanatory text of the operations for securing desired results and the general methods of manufacture. The publication will no doubt serve as a good advertisement in Russia of Canada's progressive industrial methods. A copy can be seen at the Department of Trade and Commerce, Ottawa.

MIS-USE OF GAUGES

By R. Hamilton

A FACTOR having considerable bearing upon the incidental expenses contingent to the production of shells is the maintenance of the various gauges required for the acurate machining of the parts to specified dimensions. Owing to the variety class of men now employed in munition plants, and the limited knowledge that many of them have of the actual value of percision tools, it is not surprising to see the latter misused on many occasions. Shell operators should more clearly and fully realize the importance of these test pieces, giving more attention to the handling of the same, so that their accuracy may be longer maintained. Just recently, while passing through a large shell-making plant, I noticed a young fellow using a 2 inch limit plug gauge as a hammer to force a cutting tool to a desired position.

The practice of plac- gauge as a hammer to force a cutting tool to a desired position; eter gauge on the shell, before the lathe is stopped, has a destructive effect upon the gauge, as well as tending to possible injury. Owing to the comparatively rigid construction of these tools they do not possess the spring that is so marked in the ordinary calliper and, when a shell is somewhat oversize, a seizure of the gauge results very easily, if the shell is in motion. Inexperienced operators often believe that time is saved by placing the gauge on the work just previous to its coming to a stop. Sometime ago, an operator was seen prying a large 8 inch snap gauge off a shell by using a 14 inch spanner as a hammer and lever. After removing the gauge he cautiously tried it on a finished shell and found that the high limit size would pass over. This meant that the gauge had to be returned to the tool room to have the size corrected. Instances similar to these here related mark the misuse of percision gauges in many plants, and greater attention should be given to the instruction of operators in the proper handling and care of these expensive tools.

WON'T LEAVE UNITED STATES

RUMORS that the Nathan Manufacturing Co. would move their entire fuse making department, employing upward of 3,000 men, to Canada, has been emphatically denied by Alfred Nathan, president and head of the concern. "We are far too patriotic to close up this end of our business while the United States stands in such an uncertain and critical position," Mr. Nathan announced. "If our own Government needs the resources of our company they most certainly have the first call on them."

In explaining the fact that two carloads of machines used in the manufacture of time fuses for shells had recently been shipped to Toronto and that O. Best, general manager of the factory, had left for that city, Mr. Nathan said:

"Most of our foreign munitions contracts have been completed and these machines that were sent were extras that we had no use for. They comprise only a small fraction of our equipment and would have very little effect on our possible output. The simple truth of the matter is that we had a chance to sell them to advantage and at the same time return a favor to an associate who helped us when we started into this business a couple of years ago."

Mr. Best, the factory manager, will investigate business conditions in Canada, with the possible idea of establishing a branch factory there, however, Mr. Nathan conceded. Unless the United States should need the fuse product, Mr. Nathan intimated that this branch of the business would be discontinued when the company moved into its new factory at Flushing next month.

The business originally was limited to the manufacture of ejectors, whistles, oil cups and general locomotive equipment. Since the war started, the munitions end has overshadowed the other branches.

Abrasive Materials.—Experiments recently conducted with abrasive materials used as powder for lap grinding showed that the initial rate of cutting was not greatly different for the different abrasives tested, but carborundum maintained its rate better than others, alundum was next, and emery the least satisfactory. Carborundum, however, was found to wear the lap about twice as fast, and alundum $1\frac{1}{4}$ times as fast as emery. It was also proved that the rate of cutting is practically proportional to the pressure. The materials upon which the work was done influenced the wear of the laps, which was in the following proportions: Cast iron, 1.00; steel, 1.27; copper, 2.62. Petrol and petroleum are the best lubricants to use with cast iron lap, the latter, on account of its non-evaporative qualities, being first choice. Machine and lard oil were found to be the best lubricants to use with a copper or steel lap, and lard oil with all laps and all abrasives tested, —the cutting being faster than with machine oil.

CRUDE OIL INSTALLATION FOR SHELL FURNACE

By M. W. Minster.

THE furnace, the oil burning installation of which is herein described, was built and used for heating 4.5-in. Mark VII., H.E. shells previous to the closing-in operation. The fuel used was crude oil, which at ordinary atmospheric temperatures is thick and very viscous, and for proper combustion requires to be heated. Storage was provided outside the building, the tank being located, as required by the insurance regulations, not less than five feet from the nearest wall, and with at least four feet of dirt over it. A 2-in. filling pipe led from the tank to above the ground, and a 1½-in. suction pipe connected the tank and pump. The pump was of the geared type, belt driven, and having 1-in. suction and discharge. The large suction pipe was provided on account of the viscosity of the oil..

In the discharge line from the pump, a spring loaded relief valve was provided, the discharge from the relief valve being piped back to the tank. In the relief pipe, a vent was provided leading to above the eaves of the building and terminating in a return bend. The object of the relief valve was to provide a means of regulating the pressure of the oil to the furnace, the pump speed being constant.

Constructional Principle

The discharge from the pump was a ¾-in. pipe, and was connected to a main heater. The heater was constructed on the principle of the ordinary kitchen boiler, the reservoir consisting of a piece of 8-inch pipe, about four feet long, closed at each end with a cap. A heating element, composed of three lengths of ½-in. pipe wound into coils and welded together, was inserted in the reservoir with the ends projecting through the upper cap. A city water connection was provided in the upper cap, also a pipe leading to a relief valve and a bleeder valve, the latter to bleed out a portion of the hot water if there was a tendency to form steam in the reservoir. The heating surface was provided by a loop of 1-in. pipe starting from the bottom of the reservoir, and, after passing across the top of the furnace, returning to the reservoir.

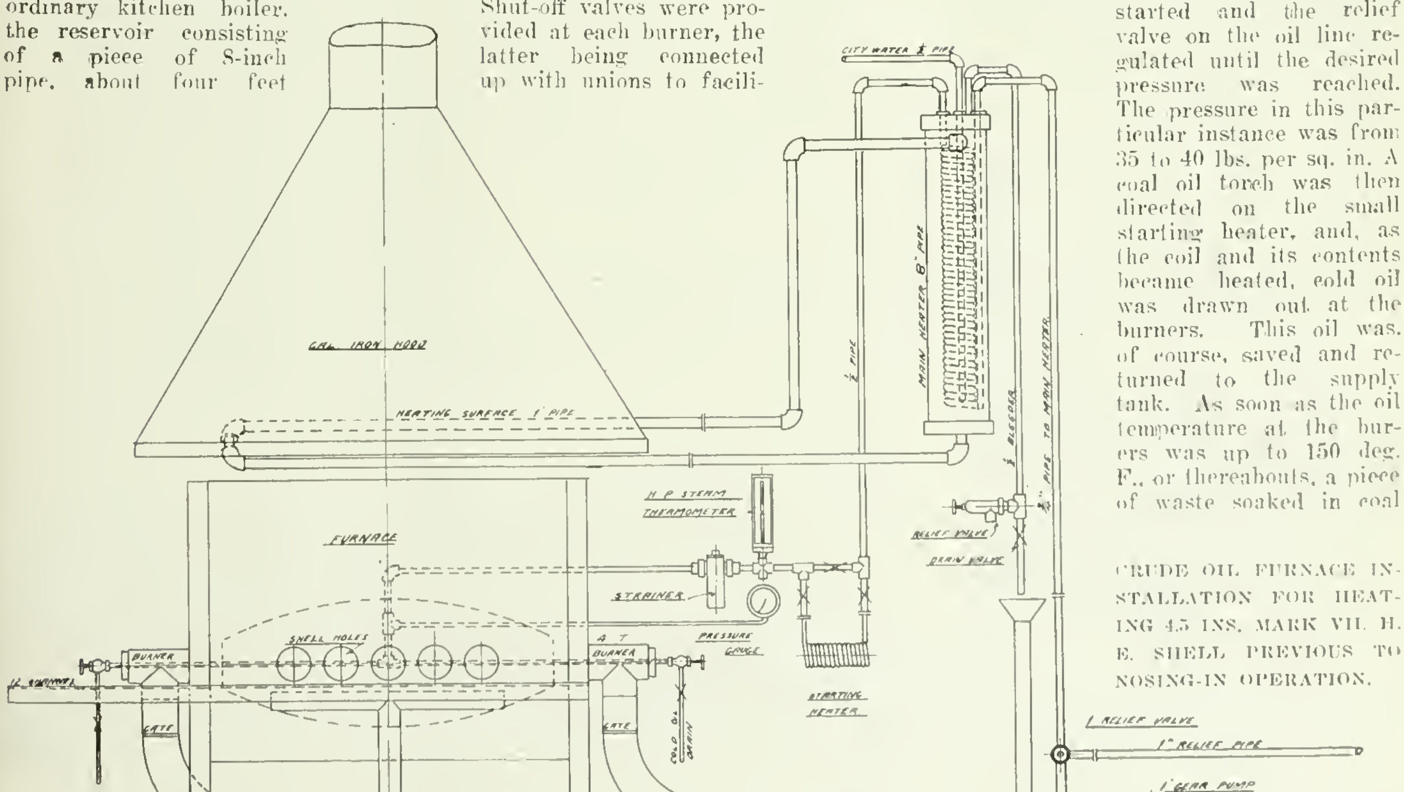
After leaving the main heater, a starting heater was installed in a by-pass in the oil line. This heater was made up of one length of ¼-in. pipe wound into a coil about 3 in. in diameter; after being connected up, the coil was enclosed with blocks of asbestos 2 in. thick to retain the heat. Just beyond the by-pass a high pressure steam thermometer was installed in a cross, and beside the thermometer a strainer was provided. The strainer consisted of a brass shell, having a copper gauze basket inside. The inlet led into the basket, which retained the fine particles of solid matter. The basket was readily taken out for cleaning by removing a plug in the top of the strainer.

After leaving the strainer, the oil pipe branched, one branch leading to each end of the furnace, where the burners were located. A connection for a pressure gauge was provided where the oil pipe divided, thus giving the pressure actually on the burners. Shut-off valves were provided at each burner, the latter being connected up with unions to facilitate removal. The burner consisted of a 4-in. T, the branch of which was connected up to the air supply from a pressure blower. One end of the run of the T was connected to the burner opening in the furnace wall, the other end being closed with a plug. Through the centre of the plug a ⅜-in. pipe was passed, the outer end being connected to the oil supply by a ⅜-in. angle valve, from which the valve was removed and the thread cut off the spindle. On the inner end was screwed a hollow casting with a double thread cast on the outside. The top of the thread filled the T, and formed a helical passage for the air.

The oil passed through the casting and entered the tip which was screwed into it. The tip was bored out to two sizes, the side screwed into the casting being ¼-in. diameter, which was reduced to 1-32 in. where the oil discharged. Leading to the small hole was a helical passage formed by inserting a small slug, on which a double square thread was cut into the ¼-in. part of the hole. As the helices of the oil and air passages were of opposite hands, the oil and air revolved in opposite directions when discharged into the furnace, greatly assisting combustion. The small slug was tapped to receive a piece of ⅛-in. wire, the other end of which was screwed into the spindle of the ⅜-in. angle valve. This construction enabled the slug to be moved out and in by hand from its working position, and, acting as a pump, often cleared a slight obstruction in the tip.

Starting Up

Starting up was carried out as follows: The oil pump was started and the relief valve on the oil line regulated until the desired pressure was reached. The pressure in this particular instance was from 35 to 40 lbs. per sq. in. A coal oil torch was then directed on the small starting heater, and, as the coil and its contents became heated, cold oil was drawn out at the burners. This oil was, of course, saved and returned to the supply tank. As soon as the oil temperature at the burners was up to 150 deg. F., or thereabouts, a piece of waste soaked in coal



CRUDE OIL FURNACE INSTALLATION FOR HEATING 4.5 INS. MARK VII. H. E. SHELL PREVIOUS TO NOSING-IN OPERATION.

oil was thrown into the furnace and lighted, and the oil turned on to the burners. If the oil was hot enough and atomizing properly it would ignite immediately. The blower was then started and air admitted to the burners.

Air Supply

The amount of air supplied was regulated to suit the quantity of oil necessary to produce the required temperature in the furnace by gates in the branches to the burners. It was delivered at 10 oz. pressure from a blower running at 3,200 r.p.m. As the furnace warmed up, and the main heater became operative, the starting heater by-pass was closed and the oil temperature allowed to rise to about 225 deg. F. The hot water bleeder was then opened and regulated, so that a temperature of from 225 to 250 deg. was maintained.

The size of the fire was not regulated by the valves in the oil supply line, but by the relief valve on the pump discharge. Increasing the oil pressure increased the amount of oil passing through the burners, and consequently increased the size of the fire. After the furnace was warmed up properly, the time required to heat a shell was from 6 to 7 minutes. When shutting down for more than a few minutes, it was necessary to remove the burners to prevent the oil in them from baking, due to the radiant heat from the brickwork. As the burners could be removed in less than half a minute, this item was a small matter. The equipment was designed and installed under the supervision of E. C. Fogh, of the Machinery Installation & Contracting Co., Vancouver, B.C.

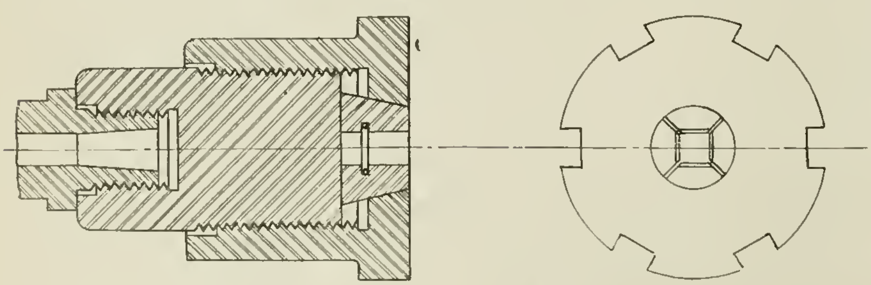
BASE PLATE CHUCK FOR 4.5 INS. H. E. SHELL

By H. A. W.

THE chuck shown in the accompanying line sketch has given excellent satisfaction in production, and has rarely called for repairs and adjustments. The main body of the chuck is made from a good grade of machinery steel unhardened. The nut is also made from good machinery steel, but is pack-hardened. A little kink to protect the thread on the chuck body is to make the threaded portion of the nut considerably longer than the length of thread on the body and then counterbore the nut, thus keeping the dirt and chips out of the threads, no part of same being exposed.

There are four jaws, these being deeply serrated on the faces that grip the base plate nib. The jaws are made from carbon tool steel and hardened. Base plate nibs are forged with a taper which varies a little in different plants. Roughly, the height of the nib is 7/8 of an inch, 7/8 ins. square at the base and 3/4 ins. square at the top end. The jaws are made to close to the above dimensions, but in order that they may accommodate themselves to a slightly different taper when necessary, the outside of the jaws is not turned a straight taper. Their surface is slightly convex, and this enables them to rigidly tighten on base plate nibs quite widely different in their tapers.

As shown in the sketch, a groove is turned at the back of the serrated surface where a small piece of music wire is placed to prevent the jaws from closing together when a plate is removed, and making it troublesome to insert another plate. In service this chuck has turned thousands of base plates, some very irregular, and we have yet to hear of one plate that has shifted under the cutting tools.



BASE PLATE CHUCK FOR 4.5 INS. H. E. SHELL.

DON'TS FOR SHELL OPERATORS

by J. R. M.

DON'T throw a shell down unless you see where it is going to fall.

Don't use a steel rule to pick off the scale on a rough forging.

Don't force a gauge over the work; it will destroy its accuracy.

Don't try to rectify a damaged gauge; take it to the tool room.

Don't forget that good work cannot be performed with dull tools.

Don't use lighted matches if cleaning shells with benzine or alcohol.

Don't forget to keep your machine well oiled; like yourself it needs occasional feeding.

Don't leave gauges lying where a shell might chance to fall on them.

Don't let your gauges lie on heated or frost covered shells; the size will be effected.

Don't forget that co-operation with your mate on the other shift means better work and more of it.

Don't start work on a new machine until you become familiar with the operating mechanism.

Don't permit your tools to become over-heated when grinding as their cutting qualities may be destroyed.

Don't leave your machine in a state of disorder at quitting time, remember you will be starting again in the morning.

Don't try to clean out with your fingers the cuttings from the small hole in the shell nose; your fingers may easily be injured.

Don't allow tools, etc., to accumulate on the saddle of the lathe, as they may easily fall off and and interfere with its travel.

Don't make a practice of gauging the work while in motion; the gauge may seize and result in injury to your hands; besides, the rough surface of the shell would soon wear the gauging point and destroy the original size.

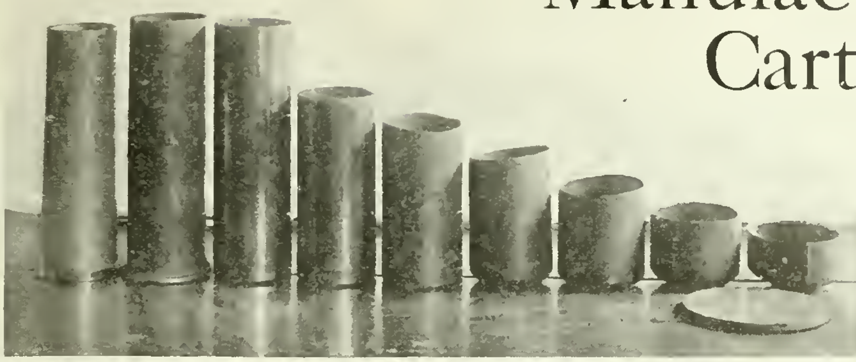
AUSTRALIAN STEEL FOR IMPERIAL GOVERNMENT

AS much as possible of Australia's production of steel is to be exported to Great Britain while the need exists, says *Australian Hardware and Machinery.* It is to take the form of steel rails and fish-plates, and the available quantity is 50,000 tons for the first six months of 1917. Intimation to the above effect was made in the Commonwealth Parliament by the Prime Minister.

The only producers of such materials in Australia are G. & C. Hoskins Ltd., of Lithgow, and the Broken Hill Proprietary Co., who recently established iron and steel works in the neighborhood of Newcastle. A sample shipment of 500 tons of shell steel went from the Broken Hill Co. to the Imperial authorities early in 1916, and brought an order for a further 1500 tons, which the company had in stock, followed by a request for 10,000 tons of round mild steel bars for munition purposes, over 2000 tons of which have been shipped.

The Ministry of Munitions then asked the Federal Government for the estimated steel output of Australia during 1917 (in separate half-years), and how much of this could be spared for munition requirements. The Premier was told by the above-mentioned two manufacturing concerns that the production would probably be 120,000 tons for the first half and 110,000 tons for the second half of the year. As already stated offer was made to furnish 50,000 tons for war requirements during the first six months, the second six months' supply to be arranged later. In subsequent cablegrams the Ministry of munitions sought a quotation for 75-lb. steel rails and fishplates delivered in Britain and France, and for the present the material to be supplied will probably take this form.

The 50,000 tons of steel is the small half of the Australian output. Every ton was already pledged to the Federal and State Governments, and only by interrupting work already in hand or deferring contemplated enterprises will the Australian Premier be able to redeem his promise. No doubt the country will stand behind him in the matter. While directly helping the cause of the Allies, it will tend to reduce Australian expenditure, and increase Australian exports. By responding to the call of patriotism, not two, but three, birds will be killed with this one stone.



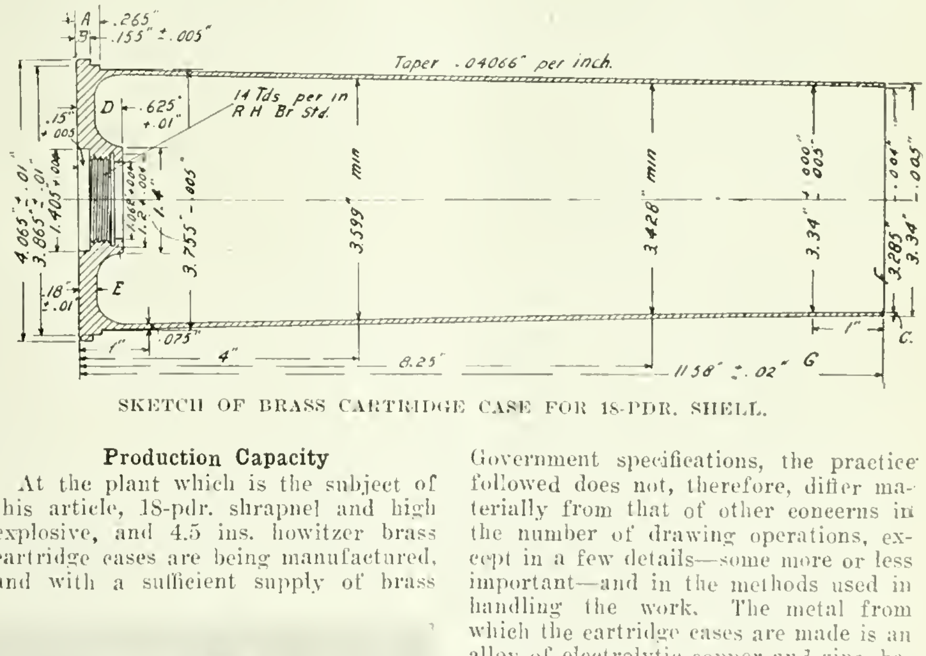
Manufacturing Brass Cartridge Cases

For Shrapnel and High Explosive Shell

Staff Article

The manufacture in Canada of brass cartridge cases for service with 18-pdr. shrapnel, 18-pdr. and 4.5 inch high explosive shell, was in its initial stages no less beset with difficulties than was that of shell bodies, fuses, etc. As in the case of the latter ,the firms undertaking production achieved early success, however, and have, without interruption, continued to add to it in very material degree; so much so, that, although fewer in number comparatively, they are easily able to meet the requirements of finished shell of the above types and sizes.

TO the layman visiting a plant where brass cartridge cases are being manufactured, the process might appear to be simple, although extremely interesting. As a matter of fact, however, the production of cartridge cases calls for considerable skill in the design of the tools employed, and satisfactory results have only been obtained by concentrated effort in overcoming the numerous difficulties that in the first instance confronted manufacturers of this product. The extreme accuracy required in the size of cartridge cases and consistency in the quality of metal require that the greatest care be exercised in their manufacture. For these reasons their production is not such a mechanical affair as the uninitiated might think. The efficiency of a plant and, therefore, its output, are , of course, greatly increased by the use of modern machinery. At this plant the equipment is all of the latest type, its general efficiency being of a high order. The buildings, too, are of modern construction and are planned expressly for the purpose for which they are being utilized; trucking and handling being thus reduced to a minimum. The ground plan, illustrated, shows the general lay-out features.



SKETCH OF BRASS CARTRIDGE CASE FOR 18-PDR. SHELL.

Production Capacity

At the plant which is the subject of this article, 18-pdr. shrapnel and high explosive, and 4.5 ins. howitzer brass cartridge cases are being manufactured, and with a sufficient supply of brass discs, approximately 750,000 cases can be produced each month. The cartridge cases are, of course, made to standard Government specifications, the practice followed does not, therefore, differ materially from that of other concerns in the number of drawing operations, except in a few details—some more or less important—and in the methods used in handling the work. The metal from which the cartridge cases are made is an alloy of electrolytic copper and zinc, being in the proportion of approximately two parts of copper to one of zinc. The metal possesses very high tensile strength when annealed and of the proper hardness; this feature will be dealt with later. The brass discs for the 18-pdr. shell case are 6.062 ins. in diameter and 0.380 in. thick. They are not made in this plant, but are purchased from various outside concerns who make a specialty of them. The discs are generally annealed in the maker's mill, and are thus ready for the first, or cupping operation when received at the cartridge case plant.

The manufacture of cartridge cases consists primarly of a series of drawing

18-PDR. CARTRIDGE CASE WITH DRAWING CLIP ATTACHED.
This is among the munitions accessories being made in Canada, and forms an interesting job of blanking, piercing and drawing.

out and pressing operations, the former to make the body of the case and the latter to form the head and indent in same for the primer. The presses which are practically all of Bliss or Toledo make, are powerful machines and are driven from the line shaft by electric motors.

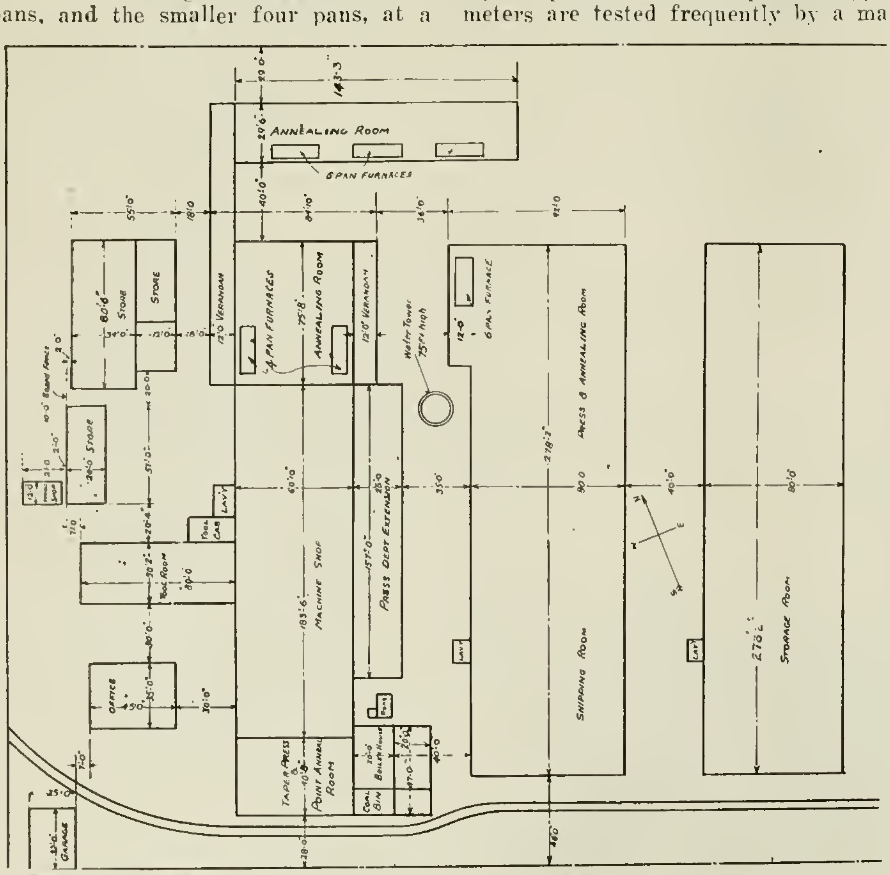
Annealing and Pickling Features

Before proceeding with a description of the main operations, reference should be made to the annealing and pickling, etc. The brass case is worked up in a cold state. The drawing and indenting tends to harden the metal somewhat, consequently annealing is necessary to restore the required ductility. The 18-pdr. cases are annealed five times; the sequence of anneals will be seen later. The annealing is done in furnaces which are all standard Rockwell type equipped to burn natural gas or fuel oil. There are six furnaces, four 6-burner, and two 4-burner; the larger furnaces hold six pans, and the smaller four pans, at a time. The oil is conveyed to the furnaces from two 15,000 gallon underground tanks, by means of a Rockwell rotary pump operated by a 3/4 h.p. C. G. E. induction motor.

The pans or trays hold from 200 to 120 cases, the number being reduced as the stage of manufacture progresses. The cases are carried to the furnace on trucks. The pans are fed into the furnace at the loading end by means of a pusher operated by compressed air. At the end of the prescribed period, the pans are pushed out at the discharge end into trucks and wheeled away to be cooled slowly in the yard outside. During the cooling process, the cases are protected from the weather by overhead verandahs. The furnaces are worked at a temperature ranging from 1,160 to 1,110 degs. Fah., according to the stage of operations, while the time occupied for annealing varies in the same way, and ranges from 56 to 30 minutes. The scleroscope tests will be dealt with later. In each furnace is a Bristol electric pyrometer connected to registering and recording instruments for determining temperatures. The operating pyrometers are tested frequently by a master pyrometer to eliminate any possible error in registration.

The cases, after being annealed, are pickled to remove any scale that may have formed on the surface of the metal. The cases are placed in wire crates and immersed in a weak solution of sulphuric acid, and then in a weak bath of cyanide of potassium, after which they are rinsed in water. The crates are handled by means of air hoists.

BRASS CARTRIDGE CASE WITH 18-PDR. SHRAPNEL SHELL INSERTED.



DEPARTMENTAL LAYOUT OF CARTRIDGE CASE MANUFACTURING PLANT.

First Operation—Cupping

To return to the first cupping operation on an 18-pdr. cartridge case, the brass disc is placed in the press and is forced through the dies, forming it into the shape of a cup. One man at this operation can produce from 380 to 400 cups an hour. The first annealing operation is now performed. About 200 cups go to a pan. They are kept in the furnace for 56 minutes at a temperature ranging from 1,150 to 1,160 degs. Fah.; after cooling, the cups are pickled and washed, according to the method already described.

Second Operation—First Re-draw

This operation is similar to the preceding one. The sides are increased in length and reduced in thickness, but the bottom of the case remains the same. The production is practically the same as for cupping, viz., 380 to 400 an hour. The cases are again annealed, pickled and washed, the annealing requiring the same time, and being carried out at the same temperature as in the first operation.

Third Operation—Second Re-draw

The second re-drawing operation is identical with the first, the sides being, however, further lengthened and reduced in thickness; the bottom as before remains the same. Production is on a like basis as that for the previous operations. During these three operations it is imperative that the bottom of the case be not reduced, as the full thickness of metal is required to form the head and indent. Annealing is not necessary at this stage, so the cases are taken over to the indent press.

Fourth Operation—First Indent

In this and the succeeding indenting operation a change is made in the character of the dies employed. In each of the three preceding operations, the embryo case was forced through a circular die by a punch traveling vertically downwards. In this, the fourth operation, the first indent, for the primer pocket, is formed in the head, the indent when finished being machined to take the percussion primer. The case is placed over a die, the head of which conforms to the shape of indent inside the case, while the projection on the punch forms the indent proper.. Two men are required for this operation, and the production is about 250 per hour. The cases are again annealed, pickled and washed. For annealing, about 165 cases constitute the contents of a pan, and the time occupied is 51 minutes, at a temperature ranging from 1,130 to 1,140 deg. Fah.

Fifth Operation—Third Re-draw

The procedure adapted for the third re-draw, and the dies also, are very similar to the preceding drawing operations, except that the end of the punch is recessed so as not to touch the indent. At this operation, the production is about 200 cases per hour with two operators. The cases are again annealed, pickled and washed. The annealing takes 42 minutes, at a temperature of 1,110 to 1,120 degs. Fah., the pan holding 160 cases.

Sixth Operation—Fourth Re-draw

The fourth re-draw is performed in a manner similar to the above operation, the same type of punch and dies being used. The case has now considerably increased in length, and production is reduced to 150 per hour with two operators. The second indenting follows, and is similar to the first indent operation except that the head is flattened a little. Two operators are employed at this operation, and the production is about 250 cases per hour. The cases—120 in a pan—are again annealed, pickled, and washed. The annealing occupies 36 minutes in a temperature of 1,110 to 1,120 degs. Fah.

TYPICAL "ROCKWELL" 6-BURNER ANNEALING FURNACE INSTALLED, SHOWING PAN LOADED WITH CASES BEING FED INTO FURNACE BY AIR PUSHER. DUPLICATE PIPES AT SIDE ARE FOR FUEL OIL OR NATURAL GAS.

Eighth and Ninth Operations—Fifth and Sixth Re-draws

There now follow two re-drawing operations, further lengthening the case, with a corresponding decrease in production. The punch and die employed in each case is the same. The production at the fifth re-draw is 150, and, at the sixth, 120 cases per hour. After the fifth re-draw, the cases are trimmd, then annealed, etc. The number of cases per pan is 120, and the time occupied is 30 minutes in a temperature of 1,110 to 1,120 degs. Fah. After the sixth re-draw, the cases do not require annealing again, but they are trimmed; in other words, the ragged edges are removed. The sixth draw increases the length of the case to about 13⅜ ins., the trimming reducing it to 12 ins.

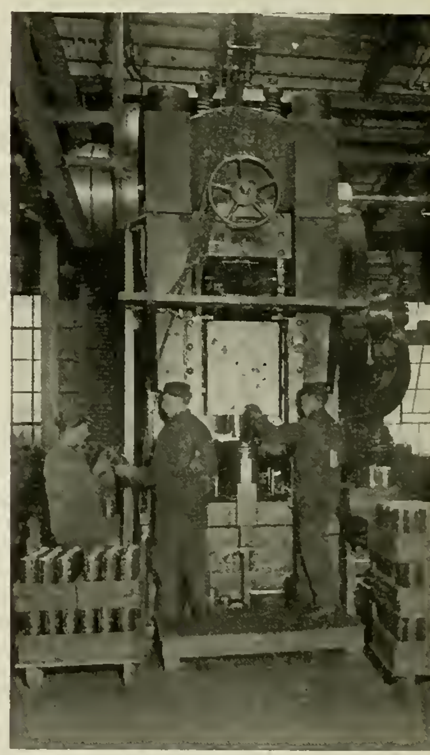
Heading

The re-drawing operations have now been completed, but the head still remains to be formed and finished. The heading is done on a powerful press fitted with two sets of punches and dies, one used for flattening the head, and the other for the final heading which includes forming the primer pocket. The ram of the press has an indexing fixture carrying the two punches, while the revolving table in the press has also an indexing fixture carrying the heading die holders. A case is first placed over the plug in the die which is indexed round until it is in line with the flattening punch. The press is operated and the head flattened out. The die holder now remains stationary while the heading punch is moved into position. The press is operated again, finishing the heading. The table is then moved round bringing the first die holder to the front and the second to the back to repeat the operation on the next case. The press is fitted with an appliance for ejecting the headed case. The production is about 450 cases per hour with three operators.

HEAVY DRAW PRESSES FOR EARLIER DRAWING OPERATIONS.

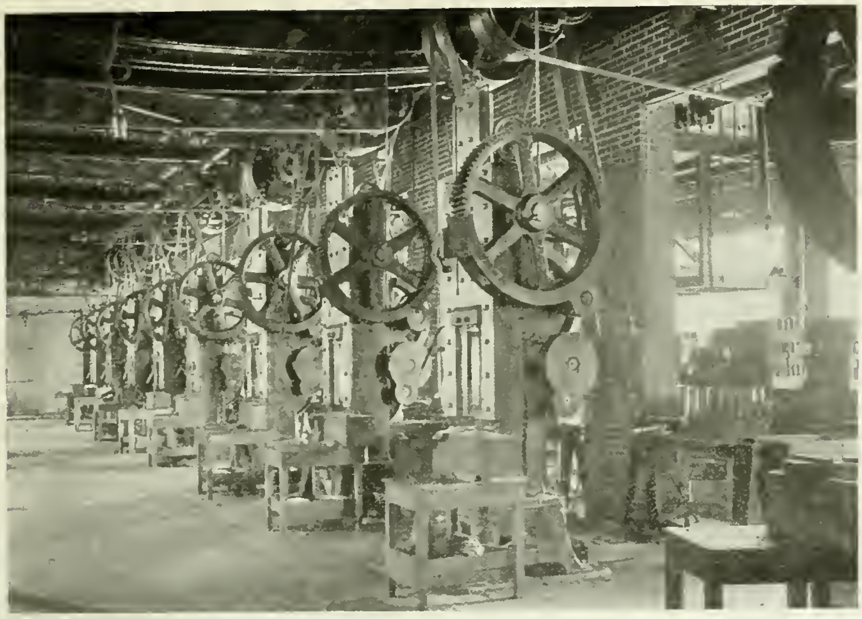
Flash Annealing and Tapering

The following constitute the tenth and eleventh operations. The sides of the case at this stage of manufacture are parallel, but must be tapered, the mouth having to take the base of shell which is of smaller diameter than the bore of the gun. Before tapering, it is necessary to anneal the case to allow of the diameter being reduced without buckling. The method adapted at the plant under review is known as flash annealing and consists of heating the cases while they are in motion. The machine comprises a revolving table carrying the cases outside and round a series of gas burners. The mechanism is arranged so as to rotate each case on its own axis while the table is in motion, thus heating them uniformly and continuously. The table travels slowly, but the cases rotate at a much higher speed.



TYPICAL HEADING PRESS.

After annealing, the cases are taken to a press to be tapered, this being done in two operations. In the first, the mouth of the case is reduced to 3⅝ ins. in diameter, the length of the taper being about 7 ins., at which point the diameter is 3⅝ ins. In the second operation, the mouth is made straight for a distance of 1 in., and is then tapered from that point to the rim on the head, making a gradual taper of 0.04066 of an inch for every inch in length. For each tapering operation, two men are employed;



BATTERY OF RACK AND PINION PRESSES FOR FINAL DRAWING OPERATIONS.

the production in each case is 250 per hour.

12th Operation—Machining Head and Mouth

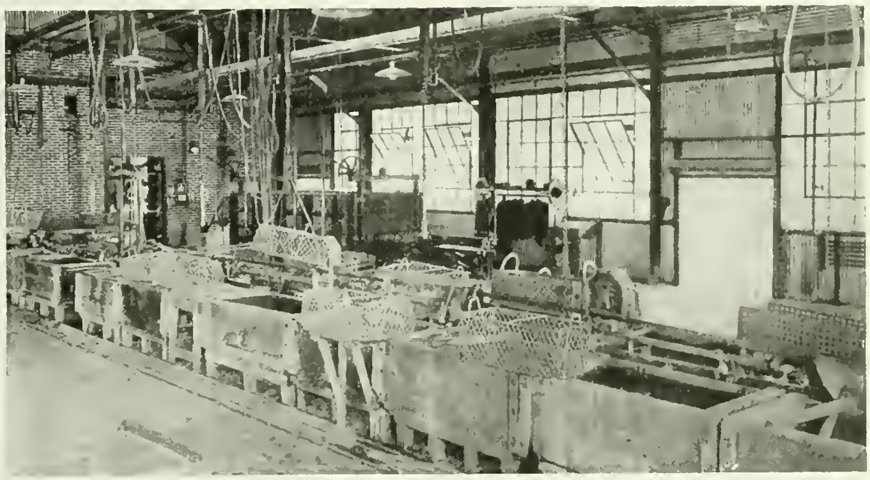
All operations involving the use of presses have now been completed, but the case is not yet finished. The head and mouth have to be machined, a number of Bullard turret lathes being used for this, the twelfth, operation. The various steps in the latter are performed in the following order:—Rough-bore primer pocket, form recess in primer pocket, face and chamfer head, finish ream primer pocket, tap primer pocket, and finally trim open end of case.

Rough Boring Primer Pocket

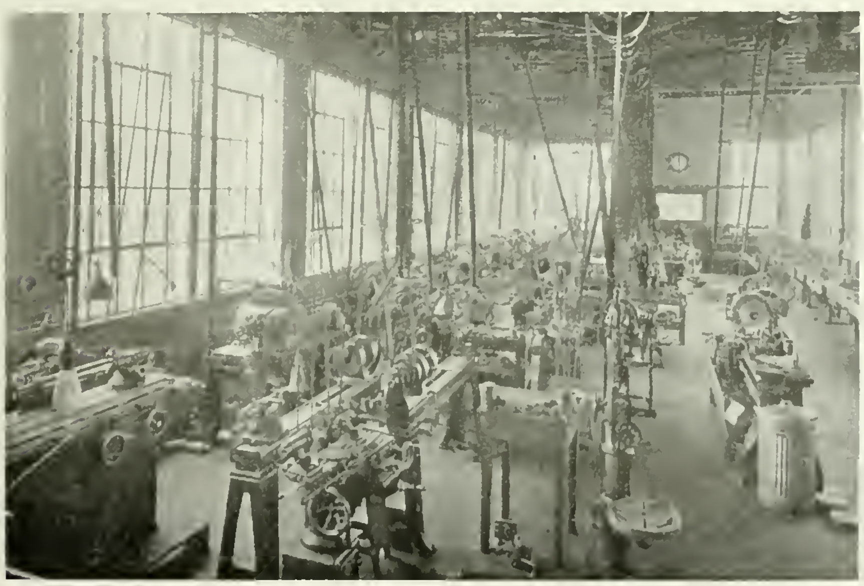
The rough boring of the primer pocket is done by a specially designed drill having three diameters. The drill is fixed in the turret, the feed being controlled by a suitable stop. The recessing tool is also in the turret and has a special feed device to form the recess at the bottom of the primer pocket. The facing and chamfering tools, or forming tools, are on a fixture at the side on the cross slide. The first of these tools faces up the head, after which the two chamfering tools form the rim of the head. A reamer on the turret then finishes the primer pocket preparatory to threading, through the medium of a collapsible tap, also on the turret. The threads are fourteen to the inch. The open end or mouth of case is next trimmed to length with a special fixture fitted to the lathe. The trimming operation reduces the length of case to 11.60 ins., which is the final length. The straight part of the mouth is then bored out to a diameter of 3.285 ins., which is the finished size.

Inspection and Stamping

A number of operations now follow. The first consists of hand tapping the primer pocket threads with a sizing tap. This is done to insure a high degree of accuracy at this important point, as the primer must be a good fit. The cases are then carefully inspected and afterwards stamped with the date, Government and manufacturer's marks, etc. The final or Government inspection next takes place. One case out of a series of one thousand is sent to Quebec for the firing test, while the balance are stored until the result is known. The cases are then packed and shipped. A conveyor system for handling cases and shell boxes is installed in the storage and shipping room, same having been supplied by the Canadian Mathews Gravity Carrier Co., Toronto.



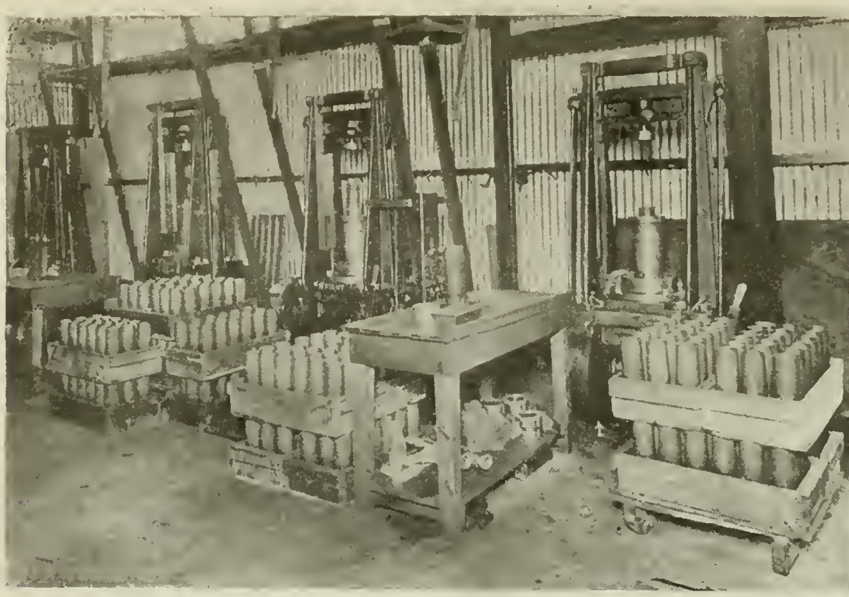
PICKLING AND WASHING TANKS IN FOREGROUND, AND TYPICAL ANNEALING FURNACE IN BACKGROUND. NOTE AIR HOISTS OVERHEAD FOR HANDLING PICKLING CRATES.



TOOL ROOM, WHICH INCLUDES PUNCH AND DIE-MAKING DEPARTMENT.

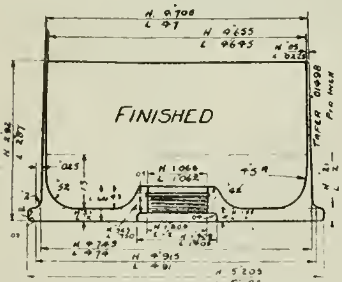
Testing

Brief mention has only as yet been made of the inspection feature which is of the greatest importance. After each annealing operation, a case is selected at random and taken to the testing room where scleroscope tests are made to determine the hardness of the metal. By this method possible errors are detected and corrected. Periodically, a case is cut in half, and readings taken on the scleroscope at various points across the section. The scleroscope tests are necessary in order that the case when completed may fully conform to specifications. This firm also employ a microscope for examining test cases to ascertain the quality of the metal; this is an



PRESSES THAT PERFORM THE TWO TAPERING OPERATIONS. FLASH ANNEALING IS DONE IN SAME DEPARTMENT.

additional safeguard against rejections. The scleroscope readings at the head range from 48 to 58, and at the mouth the average is around 40. The testing room has charge of the furnace pyrometers which are regularly compared with



SKETCH OF BRASS CARTRIDGE CASE FOR 4.5 INS. SHELL.

a master pyrometer. During manufacture the cases are frequently gauged, the allowable limit being very fine for the majority of the dimensions. The final inspection is elaborate and involves the gauging of every conceivable dimension.

4.5 ins. Howitzer Cartridge Cases

The method of manufacturing 4.5 in. howitzer cartridge cases is practically the same as that for shrapnel and the 18-pdr. H. E. Although much shorter, there is only one drawing operation dispensed with. The first four operations, annealings, etc., are identical with the 18 pdr. cases. The punches and dies are of the same design, only larger, while the furnace temperatures and annealing period are the same for both types. For the 4.5 in. case, the fifth operation is the second indent, followed by annealing for 44 minutes in a temperature of 1,150 to 1,160 degs. Fah. The third re-draw is the next or sixth operation, after which the cases are again annealed for 48 minutes at the same temperature as above.

The seventh operation is the fourth re-draw, which is followed by another annealing for 48 minutes at 1,150 to 1,160 degs. Fah. The fifth re-draw is now accomplished, on the conclusion of

STORAGE ROOM SHOWING CASES IN BOND, AWAITING RESULT OF FIRING TESTS BEFORE SHIPMENT.

which the cases are trimmed. The ninth operation, that of heading, is performed in manner similar to that of the 18-pdr. cases. The tapering operation then follows—there being only one taper in the 4.5 in. case, after which the head is machined and the mouth trimmed like the 18-pdr. cases. The primer pocket is afterwards hand tapped, inspection and stamping, etc., following same.

Conserving Scrap Metal

Not the least important feature at this plant is the care taken in collecting and utilizing the scrap material. A large melting furnace is located for the latter purpose in a separate building. The furnace is circular and has twelve pits. The scrap brass having previously been collected and bundled is melted in crucibles and cast into ingots. The brass ingots are then sold in the open market. Brass rods are also cast here for fuse body forgings. The trimmings from the

MACHINING HEADS OF CARTRIDGE CASES ON "BULLARD" TURRET LATHE. THE CASE MOUTHS ARE TRIMMED ON THE SAME MACHINES.

cases before being bundled are heated in a special furnace to remove oil, dirt, etc.

Tool Room Equipment

A very important factor in manufacturing cartridge cases is the employment of extremely accurate tools such as punches and dies. The company make all their own small tools, and for this purpose have equipped a well appointed tool room. The equiment installed comprises a number of grinding machines by various makers, including Pratt & Whitney, Brown & Sharpe, Le Blond, Ford-Smith and Landis, Blount, Davis and Oliver tool room lathes, drilling machines by the Perfect Machine Co., and Pollard & Shipman, Racine and Atkins power hack saws, and a Cochrane & Bly universal milling machine.

The company have also recently equipped a new machine shop in connection wtih the die-making department, and have installed a general line of machine shop tools. Equipment for making fuse body forgings has recently been put in operation. The brass stock from which the fuse bodies are made is cast in bars, the latter being cut up in short lengths on a circular saw and afterwards heated in a furnace. They are then stamped in a press and trimmed. The operations are simple and production correspondingly large.

In conclusion, mention should be made of the highly efficient organization at the plant, the regularity and smoothness of operation making possible an unusually high rate of production. The degree of accuracy in manufacturing is apparently very high, rejections being very few comparatively. Success of the enterprise has been proven in other ways most substantially.

CONVEYORS IN SHELL FORGING PLANTS

by M. J. Anderson*

FEW of us who are not directly associated with the manufacture of shells and forgings, realize the extensive part played by conveyors in speeding up and facilitating the handling of different commodities required in the manufacture of munitions. Space will not permit the treatment of this subject broadly enough to cover but few of the ways in which conveyors are used by munition manufacturers, we will, therefore, attempt to treat the subject only as it applies to the handling of billets and forgings.

The handling of billets and forgings, especially the six inch size and larger, is one of the most important items of expense in connection with the shell forging plant, and requires careful consideration. The way this has been solved in many plants, by the use of gravity carriers and incline power conveyors, is more or less interesting. Some of these systems are very unique in their arrangement, and have afforded savings in many ways. By this means of conveying, the minimum amount of floor space is required, and in many cases the conveyors are hung from ceiling or posts, only using floor space at the loading point, from which they raise up on an incline and continue overhead. Very little power, as a rule, is required, as the major portion of the conveyor runs by gravity, and power sections are only used where elevation is necessary.

Power Operated Conveyors

The power section illustrated in Fig. 1, is an arrangement of two endless roller chains running over sprockets at both ends. These chains are connected togethed by short pieces of flat or angle steel, making a solid steel continuous apron for shells to ride on. This is carried on four lengths of angle running under each chain, and these are riveted together with suitable angle braces and guards to prevent shells from rolling off. The down end of conveyor is arranged with adjustable bearing, permitting the chain to be tightened if slack. The top end is connected with suitable bearings and shafts, and the drive is geared back from the motor with two gear reductions and one belt reduction, cut gears and rawhide pinions being used.

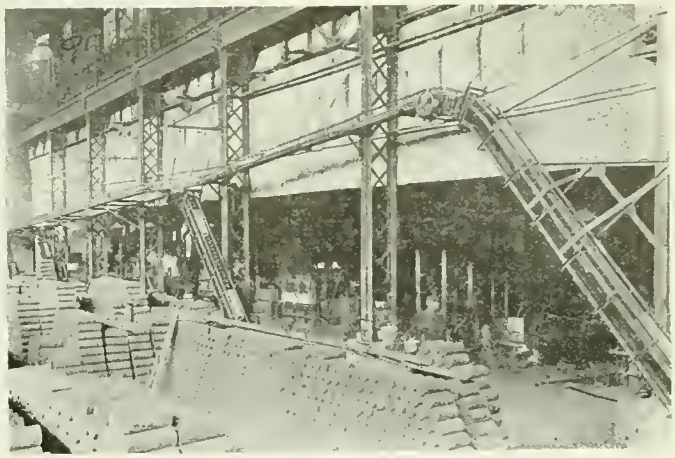


FIG. 1—POWER SECTION IN GRAVITY CONVEYOR

*Supt., Canadian Mathews Gravity Carrier Co., Toronto.

The sections of gravity conveyor also illustrated in Fig. 1, are securely connected at either end of power sections, and automatic delivery from either one to the other is made. Shells may be loaded on to the section of gravity carrier, on which they travel to elevating section, which picks them up and discharges them at top on to another run of carriers, on which they travel to desired destinations. Shells may be loaded directly on to elevator, in which case the lower end is depressed, so that the top of apron is level with floor, and shells are rolled directly on to the moving apron. Thus, by a combination of gravity and power conveyors, shells are handled any required distance at a reasonable expense, and with a minimum of power and space consumption.

Car to Stock Pile Tranfer

For the unloading of cars of billets to stock piles close to siding, several sections of gravity carriers are used. These are made up with detachable couplings and are set up on portable adjustable stands, so that with the use of curve sections and adding or taking off sections, different points can be reached as required. In many cases, however, billets are unloaded and sent direct from cars to heating furnaces, where they are fed direct or stored. Fig. 2 shows a portion of a conveyor which handles billets direct from cars, and supplies five continuous furnaces. This is accomplished by means of hinging a short section of the main line, permitting the moving billets to drop through opening, upon chutes, at the end of which, additional carriers convey them to the furnaces. Billets are fed into furnaces direct off

TWELVE CRUCIBLE CAPACITY FURNACE FOR MELTING BRASS SCRAP FROM CARTRIDGE CASES.

the carrier or from stock piles near by. When billets have reached the required heat, they are pulled out with tongs on short trolleys and are set in press and forged. They are next taken out of the forging presses and stamped, then rolled on to apron of incline elevator near by, and conveyed to cooling piles and annealing furnaces. The heat of the shells is in this way taken from the forging room, thereby increasing the efficiency of the men and adding to their productiveness.

Short runs of gravity carrier on portable supports are used from storage piles to annealing furnaces, and from annealing furnaces back to storage piles. It is also often found convenient to use these sections of carrier to connect stock piles with inspection benches. In close proximity to the inspection benches, one or two incline elevators are placed for the purpose of loading cars of finished and inspected forgings. These receive their final stamp on a block in front of conveyor which picks them up when finished, elevates them to the required height, and conveys by gravity to the cars. Fig. 3 shows conveyors loading cars of forgings, and illustrates the possible saving in space and time required for hauling.

FIG. 3—SHELL FORGINGS BEING CONVEYED FOR LOADING ON CARS.

Transporting Boxes of Munitions

In many cases, the munition plant has in addition to the forge shop, a finishing shop where all or part of the forgings are machined and boxed for shipment to powder plants for filling. In such cases, additional conveyors are used for conveying forgings from forge shop to machine shop, and between the different operations, including filled boxes to cars. A conveyor similar to the one illustrated in Fig. 1 is used to convey the forgings to the machine departments where a continuous line of ball bearing rollers, set on level, handles the shell from one operation to another. Over these light running rollers they are easily pushed from one operation to the next, saving the labor of re-handling between machines. In some cases, these level lines of conveyor run completely around the different operations, connecting every machine, and continue on to inspection and shipping departments.

Empty boxes are conveyed by gravity from box storage to shipping room, where they are packed for shipment, often without being taken off the conveyor. Figs. 4 and 5 illustrate a system of handling boxes of filled shells to cars. These boxes are first elevated to required height by an incline elevator slightly different from those used for handling the billets and forgings. This type is made with a sheet steel apron for the box to slide on, and the chains are connected with a pusher bar that engages box and pushes it up on slide. These also receive and discharge automatically in connection with the gravity carriers.

FIG. 2- PORTION OF CONVEYOR TRANSFERRING BILLETS DIRECT FROM CARS TO BATTERY OF CONTINUOUS FURNACES.

A different type of gravity carrier is also used to handle boxes. Because of the thickness and irregularity of band around these, a wheel type of carrier has been designed to meet this requirement. This consists of two rows of ball bearing wheels set on frame of steel bars, spaced at widths to suit the box to be handled. This construction allows the boxes to ride on the smooth surfaces, leaving the bands outside the rows of wheels.

In the various other branches of munition manufacture, such as cartridge case, fuse, powder plant and shell loading work, different ingenious designs and systems of conveyors are in use. We will not take the space to describe them futher than to state that in all cases they have greatly increased the manufacturing capacity of these plants by speeding up and regulating the flow of products in system and order, with the minimum use of space. Because of the lesser labor required when these conveyors are used, they are releasing men who can be used on active service or other useful production at home. Due to the high price and shortage of labor, this type of conveyor has come into universal use and has solved the problem, not only for munitions work, but nearly all other branches of industry having large quantities of commodities to handle, and has opened a way to increase production.

NO MORE ROSS RIFLES

PART of the additional information, blue prints, and specifications necessary before the manufacture of the new Enfield rifle for the Government could be commenced at the Ross rifle factories has been received. The material required is not yet complete, but it is hoped that in a short time the Government will be in a position to order the production of a new service rifle.

No Ross rifles have been ordered since February of last year, and no more will be ordered. None of the rifles being delivered under previous orders would be accepted now if the Government could avoid it. It is now stated that the Government endeavored to change delivery to Enfields of the undelivered portions of the orders already given. The terms on which the Ross Rifle Co. was prepared to meet the authorities, however, it is understood, meant that Enfield rifles could not be secured in any case except at far greater cost, and that there was practically no assurance that at any price they could be secured at all.

NEW BRITISH POLICY SOUND FOR CANADA

OUR Minister of Finance, Sir Thomas White, characterizes the speech of Lloyd George on Britain's new policy, as a wonderful epoch-marking utterance, one of the greatest, if not the greatest, in parliamentary history. "There can be no doubt," says Sir Thomas, "that the principles laid down by the British Premier are thoroughly sound and essential, having regard to the situation with which Great Britain is confronted at the present time. Two conditions have been chiefly responsible for the drastic action proposed. The first is the shortage of ocean tonnage and the second is the state of sterling exchange.

"From the latter, which is a financial standpoint, it is the proper policy of Great Britain to import only those essential things which she must have and cannot produce at home in sufficient quantity for herself and her Allies, whom she is helping to finance. These things will be found to be principally foodstuffs and munitions. She must find money abroad to pay for such as these as she purchases abroad. That is to say, for example, she must find money in Canada and in the United States to pay for the munitions, grain and other foodstuffs which she needs from these countries. She cannot pay for these imports, which have become so greatly increased over the normal, by her exports. The balance must be paid for in gold, or from the proceeds of loans made on this side of the Atlantic."

The Minister says further that the general lines of the policy laid down by the British Prime Minister were as sound for Canada to-day as for Great Britain. There is great need for increased production, especially in the agricultural sphere; there is also great need for the abolition of waste and the rigid limitation of luxurious expenditure.

"The need for national saving is," he said, "imperative. Great Britain must have money here for her purchases of foodstuffs and munitions in Canada. Every citizen should save his money and have it available for our Dominion war loans. We can get orders from Great Britain for all the munitions and other supplies we can produce in Canada, providing we can lend Great Britain the money to pay the purchase price to the Canadian producers. This can be done only by national saving. It is a time for self-sacrifice and a time for self-denial."

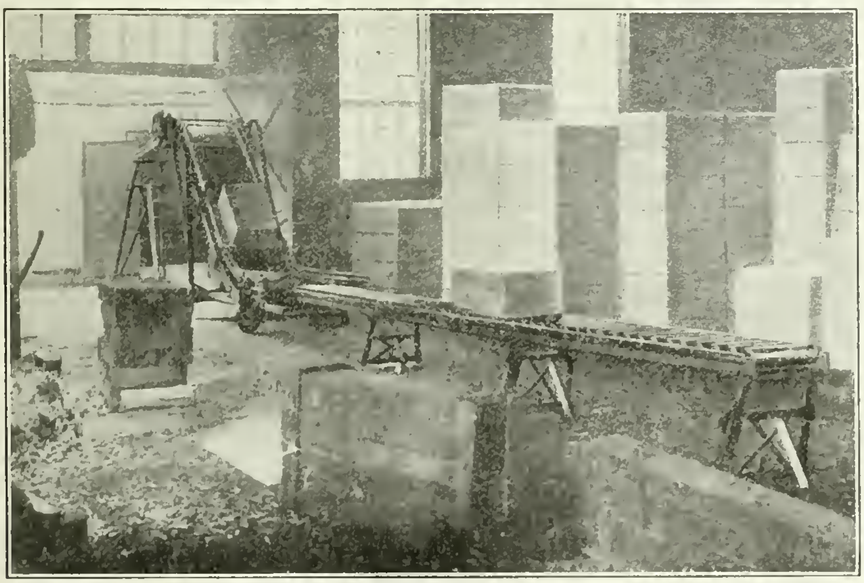

FIG. 4—CONVEYING BOXES OF FILLED SHELLS TO CARS.

TREATING HIGH-SPEED STEEL*

By A. E. Bellis and T. W. Hardy

THE problem of heat treating high-speed steel becomes more and more important as the design of cutters becomes more and more complicated in increasing the efficiency of mechanical operations. Hundreds of dollars are spent in the design and manufacture of milling cutters of special form for rapid production of duplicate or interchangeable parts, and then, as the heat treatment is faulty on the one hand, or scientifically executed on the other, the tool fails after a few operations, or its efficiency is greatly increased. The practical operation of giving these complicated tools the right temperature necessary to bring out the best cutting qualities, and at the same time bring the tool out "clean," is a difficult one and calls for no small amount of skill.

In order to be on the safe side the average tool hardener uses a temperature much too low to give the best results with the high-speed steel he uses. In the case of cutters, which are finished to a given diameter before hardening, it is impossible to grind the tool after hardening, so that it is essential that the surface be protected from oxidizing or decarbonizing. It is the aim of this paper to describe some experiments on hardening high-speed steel, in which metallographic means were used to determine the correct hardening temperatures.

The analyses for carbon, tungsten, chromium and vanadium of each steel used in the hardening experiments are given in the accompanying table. Six

Analyses of High-Speed Steels Used in Hardening Tests.

Steel	Carbon %	Tungsten %	Chromium %	Vanadium %
A	0.58	17.4	3.11	1.14
B	0.60	13.3	3.32	2.58
C	0.53	13.0	4.69	2.45
D	0.75	17.7	3.30	0.85
E	0.60	16.5	3.55	0.70

specimens from the same bar of each kind of steel were hardened from different temperatures, and photomicrographs made. Six samples were taken from the same bar in the annealed condition regularly furnished the tool maker. Photographs were made of the longitudinal section, care being taken to grind off the outer surface. The specimens, 1/4 in. were first pre-heated at 1600 deg. Fahr., and then quickly placed in the high speed furnace already heated to the desired temperature, left at this temperatude for 1 min. and quenched in oil. The temperature was controlled by a standard pyrometer, consisting of a rare-metal couple and potentiometer. An optical pyrometer of the Holborn-type gave excellent checks with the standard pyrometer, and proved more convenient and durable. A precision of 10 degr. Fahr. was attained throughout. The polished specimens were etched for 15 min. in 4 per cent. alcoholic solution of nitric acid, and photographed under a magnification of 1000 diameters.

In general, the steels that show some excess carbide even at the maximum hardening heat are the most efficient. These, as a rule, are the steels with high tungsten content; they harden from a higher temperature and over a wider range than the lower-tungsten steels. For this reason they do not require as careful treatment and are, therefore, more popular than the lower-tungsten steels. The steels with lower tungsten and higher vanadium give better results when hardened at the lower temperatures than do the higher-tungsten steels when these are hardened at the same

*From a paper presented at the February meeting of the American Institute of Mining Engineers in New York. Mr. Hardy is metallurgist, Nova Scotia Steel & Coal Co., New Glasgow, N.S.

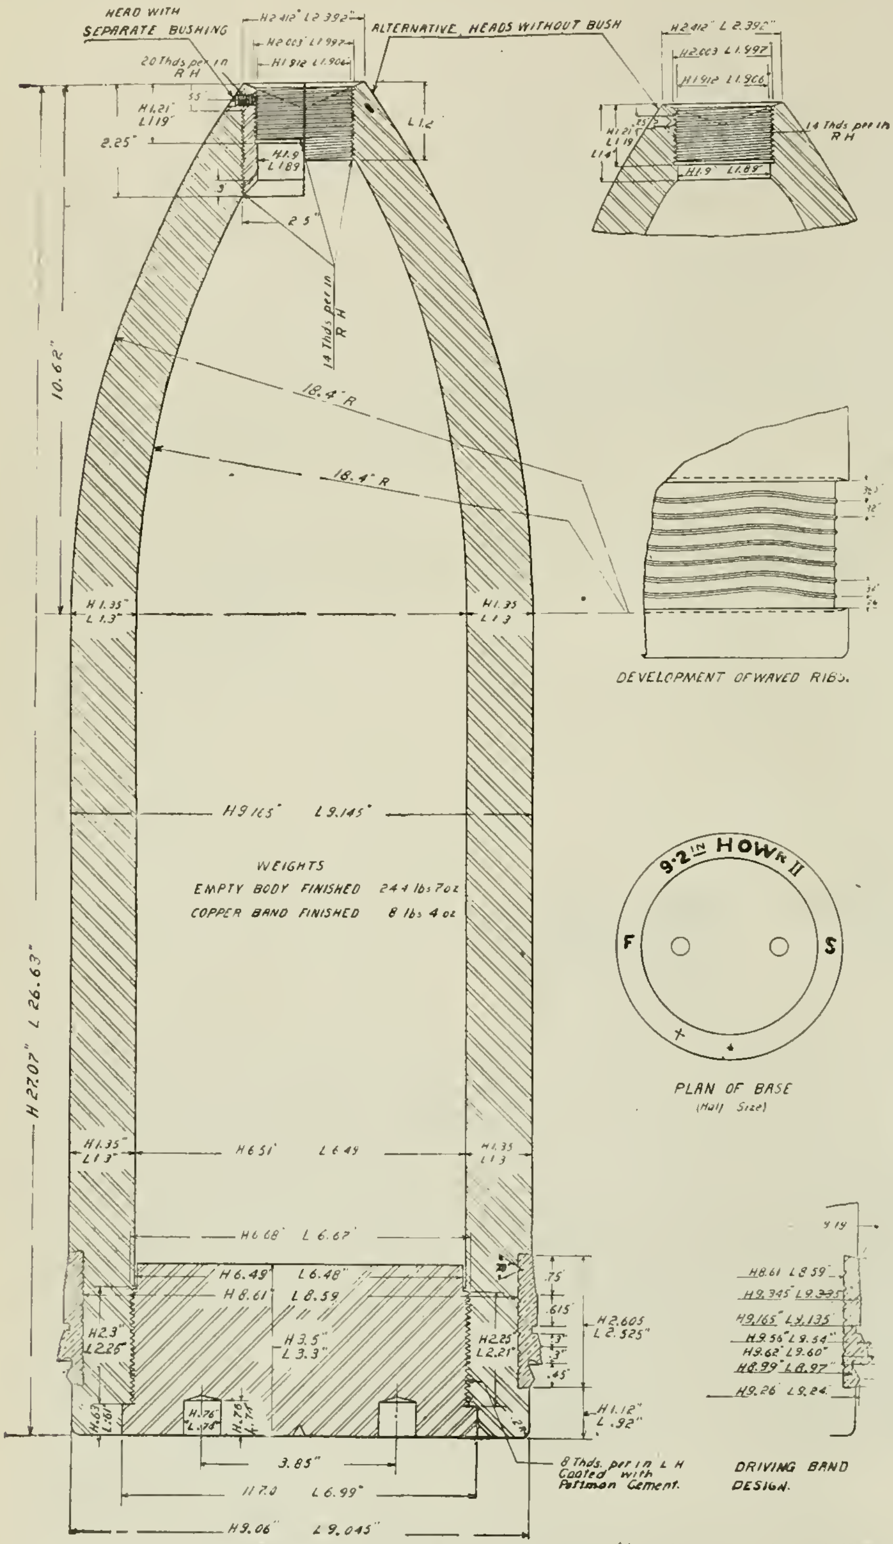
low temperatures, but the comparison is not so advantageous to the lower-tungsten steels when the steel with higher tungsten is given the proper hardening heat.

Hardening Temperature Control

The importance of carefully-controlling the hardening temperature, and of varying it for the particular steel used, cannot be over emphasized. The custom of using one "high-speed temperature" for all tools is very poor practice, for, as shown by the photomicrographs, the best structure may be obtained with one steel at a temperature which will "burn" another, or not harden a third. Thus 2300 deg. Fah. or over is necessary to give A or E a good structure, but this temperature gives a coarse grain in the other steels or "burns" them. Again, a temperature as low as 2150 degs. Fah. can satisfactorily harden B or D, but tools made of other steels would not stand up if hardened at this temperature. More extreme examples could be cited, but the samples chosen are typical of the most widely used brands of such steel.

The average hardener rarely obtains the best result from his steel. The reason for this is, especially in the cases of tools that cannot be ground after hardening, that oxidation becomes a serious problem at higher temperatures. The use of a barium chloride bath to eliminate this difficulty has the disadvantage that the surface of the tool becomes decarbonized. A method that has proven satisfactory is to place the tools after preheating in the reducing atmosphere of a carbon resistance electric furnace already heated to the required temperature. The very short time necessary to get the tool to the temperature of the furnace eliminates deleterious surface effects. Pack hardening often gives good results but, owing to the great affinity of iron for carbon at high temperatures, care must be taken to reduce this carbonizing action to a minimum. This may be done by selecting a packing material of little or no carbonizing power, and by cutting down the time during which the metal is in contact with the packing material.

The increased efficiency and cutting power of tools that have received the proper heat treatment is out of all proportion to the time given to the study of the particular steel involved, and to the care exercised.



TYPICAL 9.2 INCH HOWITZER SHELL. THE 8-INCH PROJECTILE EMBODIES THE LIKE GENERAL FEATURES.

OFFICIAL PRICE OF ALUMINIUM

THE selling price of aluminium ingots of ordinary commercial purity of 98-99 per cent. has been fixed by the British Ministry of Munitions at $1,125 per ton, carriage paid to consumers' works. The maximum selling price of re-melted aluminium scrap and swarf ingots of 98-99 per cent. purity has been fixed at $1,050 per ton, carriage paid to consumers' works. The maximum price must not be exceeded, but a lower one may be fixed by agreement between the seller and the buyer, based upon the metallic aluminium content. These prices took effect as from 1st January, and permits under Regulation 30A of the Defence of the Realm Regulations will be granted only for such dealings in the above-mentioned materials as are in accordance with the above prices. The above prices are subject to alteration, at any time, as may be directed by the British Minister of Munitions.

Damping Their Spirits.—A little boy was reading in his Scottish history an account of the Battle of Bannockburn. He read as follows:

"And when the English saw the new army on the hill behind, their spirits became damp."

The teacher asked the boy what was meant by "damping their spirits."

The boy, not comprehending the meaning, simply answered:

"Pittin water in their whisky."

8 ins. H. E. Shell Production by Public Utility Corporation

Staff Article

As no two men think alike, and local conditions are more or less varied, it is quite obvious that methods of manufacture of a given product will differ somewhat. In addition, the nature of pre-war equipment installed, and the specific service to which it had then been applied, have not been without effect in creating considerable divergence in the routine and practice of shell-making, although equal degree achievement be the ultimate outcome.

WHILE the finished product in every instance must conform to rigid specifications, the methods of achievement are more or less questions that each firm have to decide for themselves; and in this connection it might be said that the modernly equipped shop does not always necessarily show the best results.

Contributories to Success

The plant from which the following data were obtained has met with notable success in the production of 8-inch howitzer shell, largely because of the elimination of unnecessary machining, handling and transportation operations. The management decided on a tool layout that would avoid any "backing up" on the progressive movement of the shells through the shop. To insure greater accuracy in machining, the various settings of the work have been reduced to a minimum, a preference being evident to involve fixtures and attachments whereby two or more operations could be accomplished at the one time, thus eliminating the unproductive factor. It is not here intended to dwell on the details of manufacture at this plant, in extenso, the purpose being rather to give to our readers a racy outline description of some of the more interesting methods employed to secure economic and rapid production.

Owing to the inability to store the rough forgings in a closed or heated building, the accumulation of snow-frozen and otherwise, is unavoidable; therefore, before delivery to the machine operators, it is necessary to remove at least the greater part of the ice and moisture adhering to each individual forging. The method adopted, and one that has proved highly satisfactory, is to roll the forgings along a slightly inclined runway, within which are heated steam coils, the heat from these being sufficient to accomplish the desired purpose while the shells are moving slowly along the supporting rails.

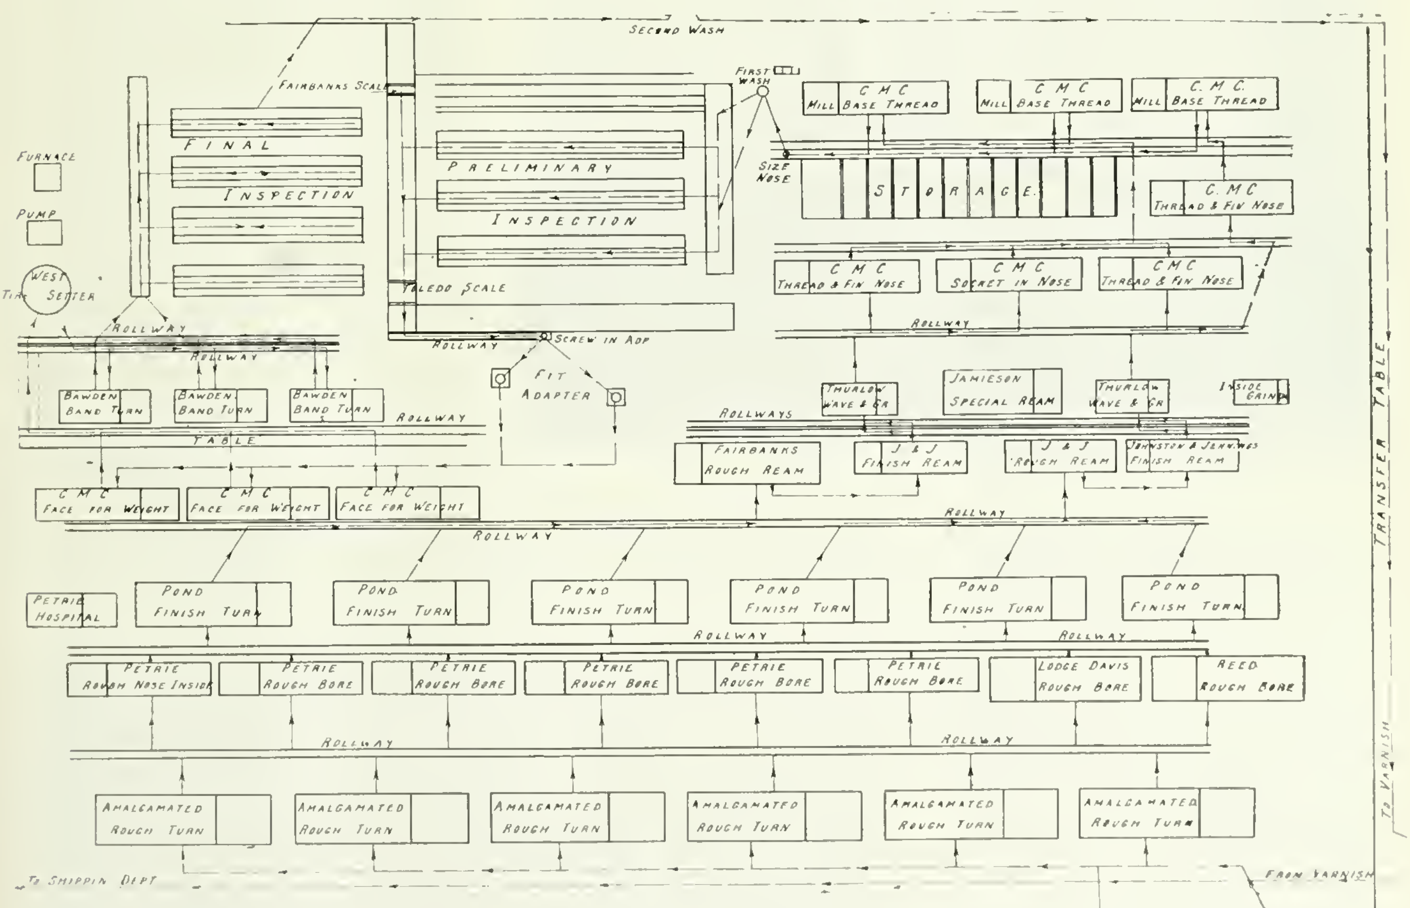


FIG. 1 MACHINE TOOL LAYOUT FOR 8 INS. H.E. SHELL FINISHING.

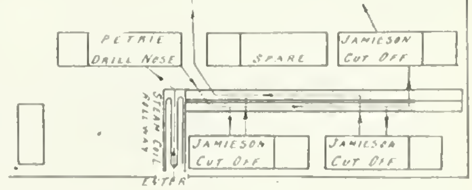

Drilling the Nose

The forgings are first tested for rough lenth and general concentricity, after which they are drilled through the nose. The method adopted for this operation differs from that employed in some other plants, inasmuch as the shell is held in a horizontal position while the work is being performed. A special heavy turret has been placed upon the saddle of a Petrie lathe, the housings being of ample weight to rigidly support the bar and maintain it in proper alignment. The turret is locked in a permanent position when drilling, but can be swung outwards to remove and replace the shells. The bar upon which the shells are placed is of the expanding type, operated by means of a wrench at the opposite end. An effective method of feeding has been devised by fitting an air-brake cylinder to the bed, between the shears and back of the saddle. The advantage of this device is a steady but elastic feed, and central thrust.

thus eliminating any irregularity in the movement of the saddle. The feed control is obtained by means of a motorman's brake valve. Care has to be exercised, when the drill is breaking through, to release the air and finish with the hand feed.

Twixt Operation Handlings

The handling of the shells to and from the various machines is a very important factor in shell production. The facilities for this purpose must not only be efficient, but should be so designed as to eliminate the chance of a shell slipping out should the tongs or lifting clamp rest upon any object. The tongs shown in Fig. 3 can be locked upon the shell when in use, and quickly released when required. The section A which carries the eye bolt B is about six inches wide, while the opposite side is about three inches wide, and is secured to A by means of the bolt D. The clamping screw E can be made of any desired length, as it is often desirable to use it to place the shell at some distance at the back of the machine.

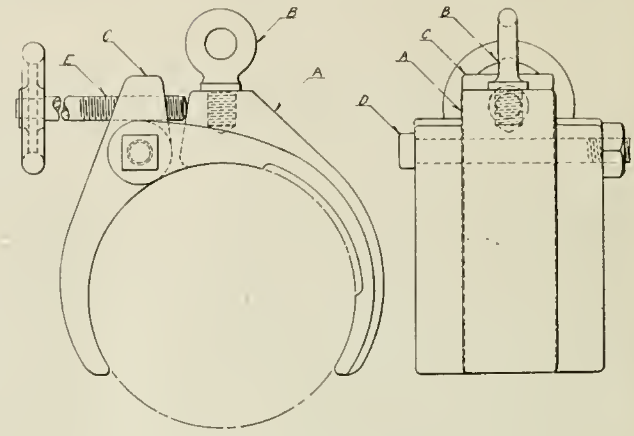

FIG. 3. SHELL LIFTING TONGS.

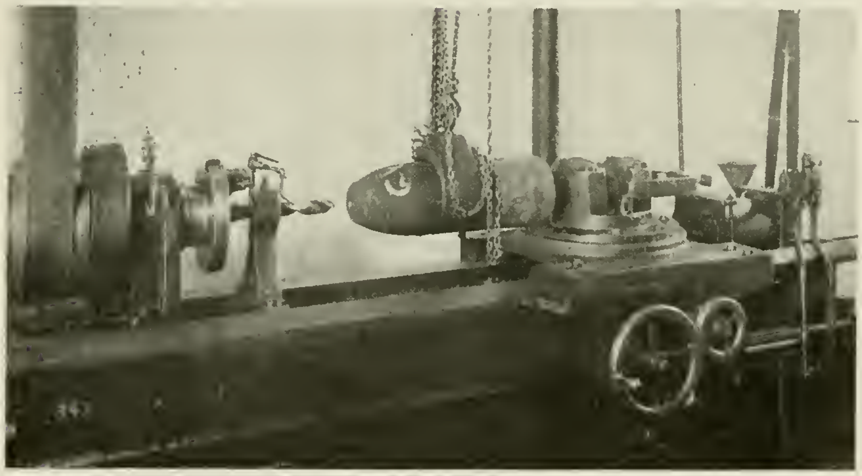

FIG. 2. DRILLING SHELL NOSE ON "PETRIE" LATHE.

Accuracy in Primary Operation

Contrary to the general method followed in many shops of allowing wide limits on the preliminary operations the practice in this plant is to commence at the very beginning to work very close to the high and low limits of specified dimensions. Experience has shown the efficiency of this system, as it has been found that it is as easy to start on an accuracy basis, and continue to do so, as it is to leave much to chance at the beginning and subsequently find that certain operations are actually being performed a second time. Fig. 4 shows a dimension sheet for primary operations; a sectional view of the finished shell being shown, together with an outline of the rough forging. Determining a point from which all subsequent measurements could be taken was the essential problem, and, after due consideration, a diameter of 3 3-16 inches on the inside rough profile was decided on as a base; from this the evolution from forging to finished shell commenced. It was calculated that his position was the most desirable, as it would give the greatest degree of accuracy, owing to the fact that the forging punch, at this point, would retain its shape for a longer period than one closer to the nose. When the forgings are first received, a disc gauge of 3 3-16 inch diameter is put in the shell, and if the depth from the disc to the outer surface of the nose is not below $3\frac{5}{8}$ inches, it is an indication that sufficient stock is available for internal and external machining.

Cutting to Length and Roughing

Three Jamieson lathes are used for cutting to length, both ends being removed at the same time. These lathes are fitted with expanding arbors, having a nose similar to that shown in Fig. 4, with a diameter of 3 3-16 inches. The cutting tools are set in a permanent position, that for the open end being 19 5-16 inches from the nose of the arbor, while that for the small end is set 4 inches from the same base. It is very obvious, therefore, that succeeding machining operations must be acurately performed, as over-all length after cutting-off is within 1-16 inch of the finished dimensions. One Bridgeford and six Amalgamated lathes are working on the rough turn operation.

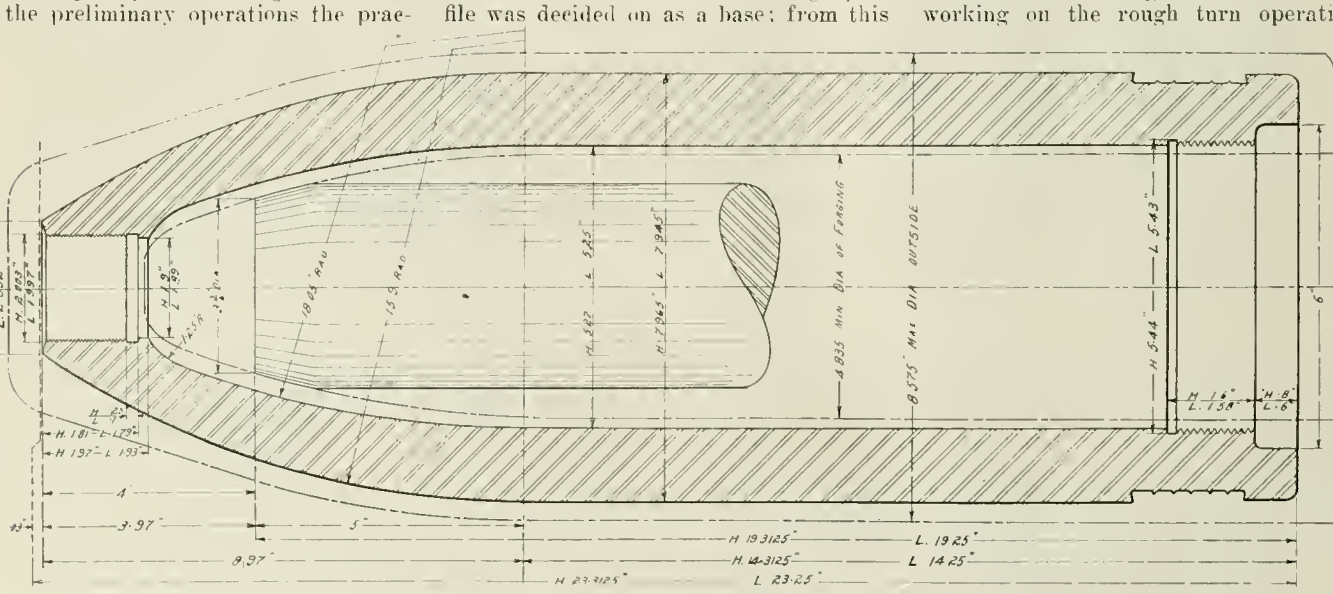

FIG. 4. DIMENSION SHEET FOR PRIMARY OPERATIONS, WITH SECTIONAL VIEW OF FINISHED SHELL, ALSO OUTLINE OF ROUGH FORGING.

Here again the gauging reverts back to the base before mentioned, but otherwise the machining is very similar to that in other shops.

Roughing the Bore

Rough boring, as accomplished in this plant, is somewhat of a departure from the general practice. Five Petrie, one Lodge-Davis and one Reed machines are used for this purpose, each being fitted with a special boring attachment as illustrated in Fig. 5. The operation of this device will be better understood by referring to Fig. 6. The chuck A, which is secured to the face-plate of the lathe, is of the pot type, the outer end being supported in the steady rest C. The boring bar, $4\frac{1}{2}$ ins. in diameter, is clamped to the turret F by means of the cap E. The radius rod connection G is clamped to the rear end of the bar, the link stud being located at same distance from the centre of the turret as the cutting point of the radius tool, which is placed directly back of the notched forming cutter. The radius rods H, one above and below the bar, have a centre length of 18.05 inches, this being the radius of the inside profie. The centre of motion from which the radius rods oscillate is on the slide I, this slide being adjustable on the bracket J. The angle iron K that supports the ends of the push bolt L is secured to the saddle of the lathe. When the attachment is in the position shown, the centre of the bar D is in the same axial line as the lathe spindle, thus permitting the staggered notched cutter to rough out the extreme nose of profile, the depth being gauged by an adjustable bolt located in the front cap of the turret, and bearing against the base of the shell.

When the gauge bolt is in contact with the face of the shell, the feed (reverse) is engaged, and the saddle starts backwards, the radius bracket J remaining stationary, causing the outer end of the link to sweep through an arc having a radius of 18.05 inches. This motion is consequently transmitted to the opposite end of the bar and tool, thus forming the desired contour. When the nuts on the push rods come in contact with the radius rod bracket, the entire device will travel in unison with the saddle, and the tool will, therefore, have a parallel motion through the remainder of the shell bore. This method of roughing out the interior of the shell has many advantages, not the least of these being the great saving effected in the amount of tool steel required, which at the present time is a very important factor.

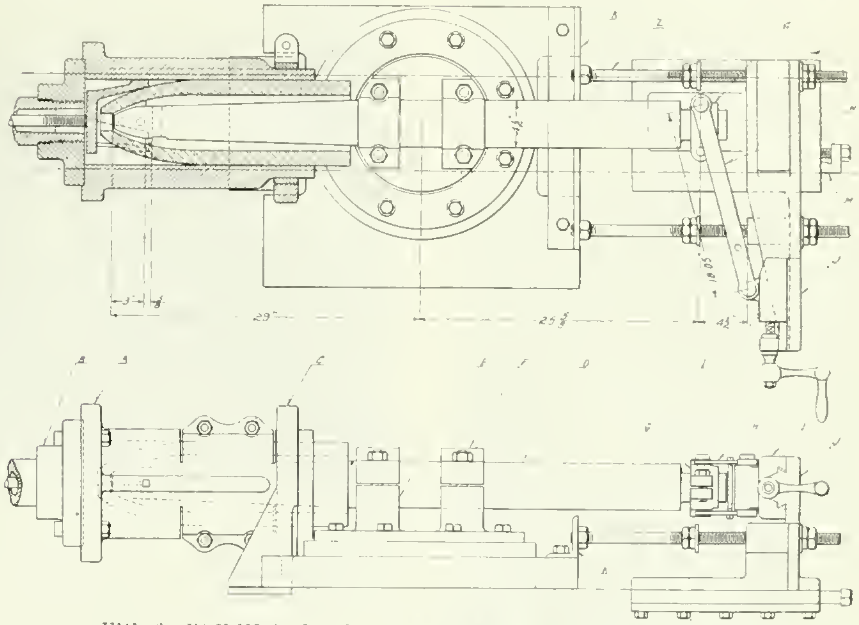

FIG. 6. ROUGH BORING ATTACHMENT ON "PETRIE" LATHE.

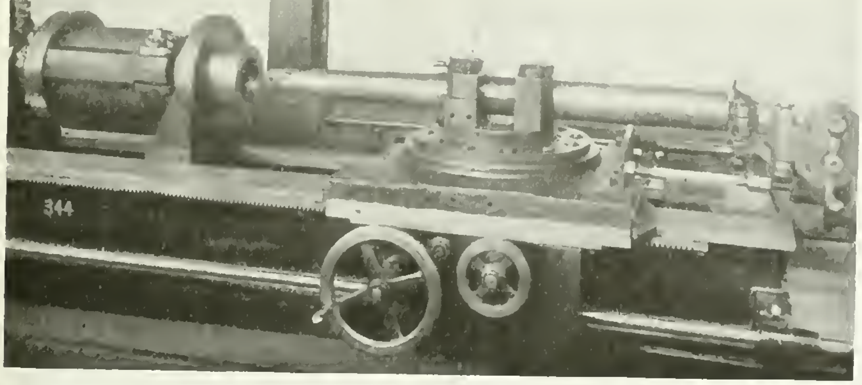

FIG. 5. ROUGH BORING ON "PETRIE" LATHE WITH ATTACHMENT AS DETAILED IN FIG. 6.

Finishing the Outside Diameter

For the finish turn operation, six Pond lathes are installed, each equipped with special profiling attachments. Cams were used for a time, but were afterwards replaced by radius links, this method proving more effective. As the shells have been cut off to within 1-16 inch of the finished dimensions, the closest degree of accuracy is required in setting the tools and tangential point of profile. Tools are set with a special gauge in order that no variation may arise in the starting of the cut. The profile attachment is permanently set for a maximum length shell, and, where a shell gauges short, a thin liner, corresponding to the amount lacking, is placed over the control rod, thus shifting the tangential point to the correct position.

Reaming the Bore

While the method generally employed is to revolve the work when finishing the bore, a reversal of this practice has been adopted in this plant. For the machining of this portion of the shell one Fairbanks and three Johnson & Jennings lathes are installed, these usually working in pairs; that is, two on the rough ream and two on the finish. A fifth lathe is provided for the final finishing of those shells, the interior of which have not cleaned up on the pre-finish ream. The reamers on this lathe are those received direct from the tool room, and are made to the largest tolerance of bore diameter and profile. As the reamer on this machine becomes dull, it is transferred to the ordinary finishing lathes, the cutters still being well within the limits of tolerance. When the cutters wear to the point where the low limit is reached, they are transfered to the rough reaming operation. By using the reamers in this way it has been found that a great saving has been effected, both in time and material. The second or finish ream generally brings the bore to size, but when the marks from the rough boring are too pronounced, it is deemed advisable to smooth the surface by working to the high limit, necessitating a third reaming on the fifth machine. The reamers are of the solid, three-blade type, and excellent results are being obtained. An approximate amount of metal removed on the two operations would be from 1-64 to 1-32 inch. The neutral diameter of the finished bore is 5.26 inches, with a high and low tolerance of .010 inch.

As shown in Fig. 7, the shell is clamped in a heavy and rigid fixture secured to the saddle of the lathe. This fixture is machined out in its working position, thus assuring accurate alignment. The feed is obtained by means of large diameter, belt-driven pulleys. A gauge is secured to the front bearing of the headstock to indicate the depth of bore. This, however, is only a guide for saddle travel, the actual depth being determined by a special gauge, shown resting close to the saddle of the lathe. This small but interesting device is largely responsible for the successful results achieved. Owing to the fact that the machining on the nose bore has not been accomplished at this stage, it is apparent that accurate gauging for depth of metal would involve considerable guesswork without a suitable gauge.

Gauge for Depth of Nose

A sketch of this gauge is shown in Fig. 8. The reamers are provided with a tit on the nose end, small enough in diameter to pass through the drilled hole. The gauging points, as shown by ring A, are taken at a diameter on the reamer, or inside profile, of 2 inches, and on the external nose of shell of 2.4 inches. These points never vary, they being $1\frac{1}{4}$ inches apart. As the extension on the reamers may vary in length, adjustment is necessary when setting the gauge, but when once set it remains constant until the reamer is replaced. When a new reamer is placed in the machine, the ring A, together with the gauge B, is placed on as shown, and, by means of the screw C, the gauging point E is set to enter the centre in the end of the reamer. It is then locked by means of the nut D. When reaming is in progress, the ring A is removed, and the gauge B placed on the nose of the shell, so that when the point E fits the centre of reamer, the depth is correct. The ring A is for the Mark III., and that at F is used on the Mark V.

Waving and undercutting is accomplished on two Thurlow machines. Two tools only are required to complete the groove, the waving tool cutting in the full depth without previous roughing. The sides are then undercut.

Threading the nose is performed much in the same way as in other plants, with the exception that the tools are secured to a fixed slide instead of the ordinary turret, the cross slide being located in the different positions by adjustable stop gauges. Four C. M. C. lathes are used on this operation, one of them being fitted for the socket hole in the alternative nose.

Base Finishing Operations

Machining the base and cutting the thread for the adapter is performed in an interesting and efficient manner. Fig. 9 illustrates the fixture as used on several C. M. C. lathes. The set-up is similar to that for the nose, the boring tool and milling cutter being fixed in a parallel position on the cross slide, and being moved latterly to the working positions. Fig. 11 is a sketch of the hob milling attachment. The rest A is for holding the tools and cutter, while B is the driving pulley and C the cutter. The driving device E for hob milling is described in detail later. At G is seen the bracket with reducing gears, H being the extension to the back of the shifting lever to which the safety cord I is attached. The pulley J, round which the cord passes is bolted to the bracket secured to the end of the lathe. The upper end of the cord I is tied to the tilting lever K, which is pivoted to the hanger.

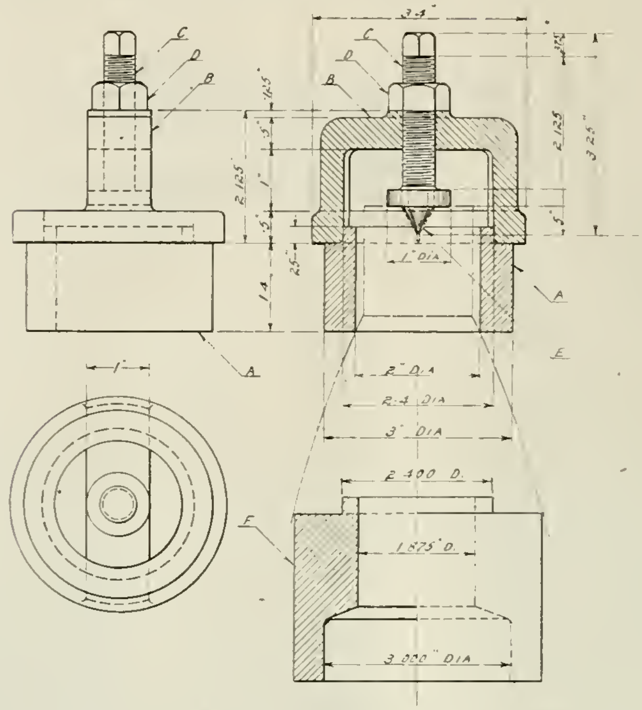

FIG. 8. GAUGE FOR DEPTH OF HOLE IN NOSE.

When the lathe is being used for cutting the counterbore, the stick K will be in the position indicated by the dotted line, but, when hobbing the thread with the reducing gears in mesh, the stick will be in the position shown, thus preventing the operator from throwing on the driving belt while thread is being milled. The jib chane illustrated in this cut is typical of those used throughout the shop. The milling fixture is of home design, being constructed from existing parts about the plant, this practice being one of the features of the equipment generally.

Driving Device for Hob Milling

A sectional view of the driving device for hob milling the threads is shown in Fig. 12. Fitted to the nose of the lathe spindle is the adapter B, the outer end being threaded 16 to the inch. This piece is connected to the shell nose centering ring by the feed nut C, the latlet being threaded right and left hand of similar pitch. The nose plug is screwed into position in the shell and then drawn back firmly in the ring chuck D. It will be noted that the thrust collar F on the operating shaft G bears against the shoulder of the piece D, so that the shell is free to advance when thread is being hobbed. The positive drive is effected by the clutch formed by tongue and groove between the pieces B and D.

When a thread is ready to be milled, the cutter is placed in position, the slow speed reducing gear engaged and the feed nut locked by means of a bar placed against the clamp bolts, and resting in a bracket secured to the shears of the lathe; this can be clearly seen in the illustration, Fig. 9. As the lathe spindle slowly revolves, the shell gradually advances at the rate of ⅛ inch per revolution, this action resulting from the turning of the right and left hand threads, of 1-16 inch pitch, in the stationary nut C. About a revolution and a quarter is given for each shell. Before the next shell is placed in the chuck, the feed nut is turned back to its original position. A sketch of the reducing gears is shown in Fig. 13.

Sizing the Nose and Washing

Following this operation, the thread in the nose is finished to size, a new tap being used for the purpose. The method adopted for performing this work is simple yet very efficient. The tap is held in a pneumatic air drill which is supported by means of a cable directly above the floor chuck that holds the shell. The motor is counterbalanced so

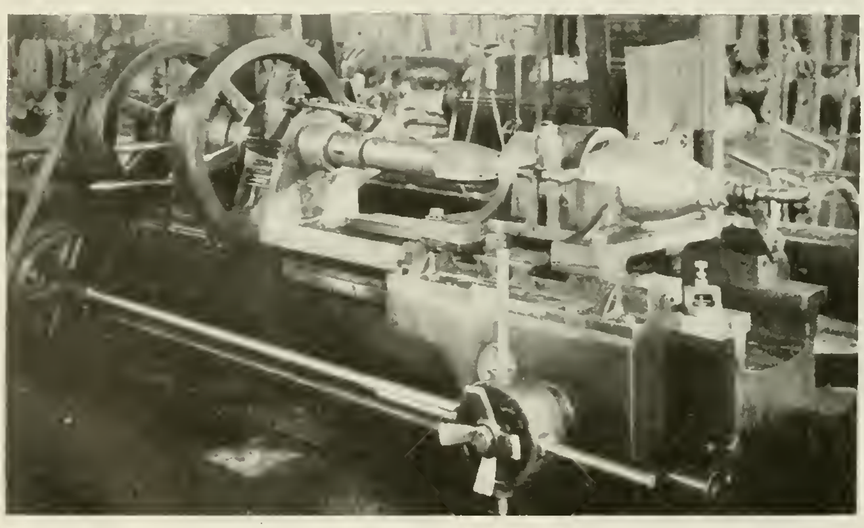

FIG. 7. FINISH REAMING ON "JOHNSTON & JENNINGS" LATHES.

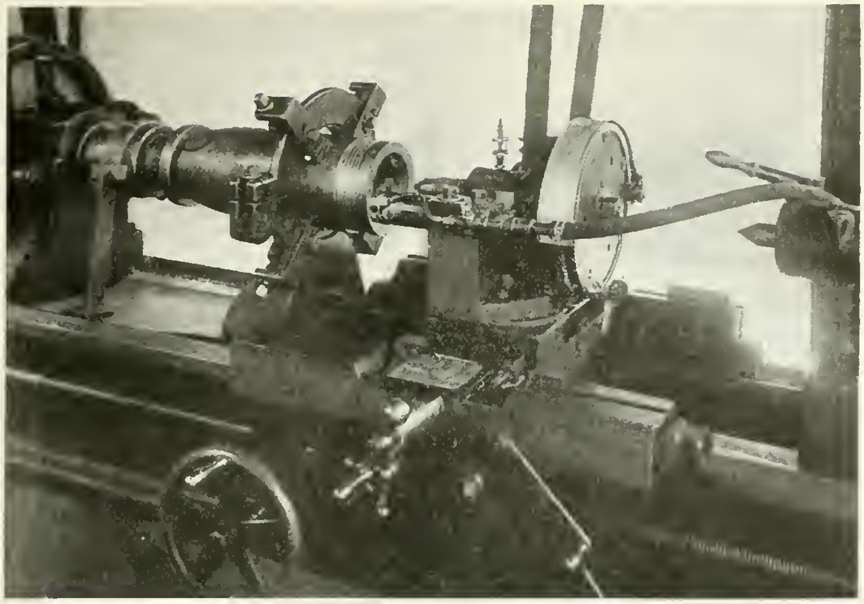

FIG. 9. FRONT VIEW OF BASE THREAD MILLING ATTACHMENT ON C.M.C. LATHE.

that very little effort is required to operate it.

Before being weighed, the interiors of the shells are thoroughly washed by means of benzine, this being applied in a manner that insures the liquid reaching all parts of the bore. The shell is placed base downwards in the centre of a small tank and over a vertical pipe that extends almost to the nose of the shell. This pipe is well perforated, and, when the pressure is turned on, the liquid is forced against the inner walls of the shell, removing all traces of grease and dirt.

Weighing and Marking

Inspection for weighing and marking, which follows the washing process, is done on a Toledo scale, and the practice in vogue is deserving of special mention. As the maximum amount of stock that can be removed is only 1-16 inch, this being the working limit during progressive operation, four finished adapters, having collars varying in thickness by 1-64 inch, are provided for checking purposes. The depth of base counterbore is measured, and the adapter, whose shoulder corresponds to this measurement is placed on the scale together with a copper band that has previously been machined; the three pieces are weighed, and, from a carefully prepared table, the exact amount of metal to be removed from the base of the shell, irrespective of the adapter used, is readily determined. When the weigher marks the shell for final facing, he does it with a double prick punch, which serves two purposes: the mark close to the base indicating the base facing, while the one higher up serves as a check on the operators. By this method any error can be immediately traced to the proper source.

Turning Copper Band

Succeeding operations are much similar to others of the same nature and need no special mention, but it might be well to note that the turning of the copper bands is being accomplished without the use of special features, this work being performed on an ordinary engine lathe with much success. The scaly surface is first removed by using a single pointed tool, after which the band is shaped with a forming tool held in the tool post of the lathe, the groove and serrations put in, and, lastly, the outer diameter finished with a tool at the back of the saddle. This latter tool is set in a permanent position every morning by a tool setter, and seldom requires further attention during the day.

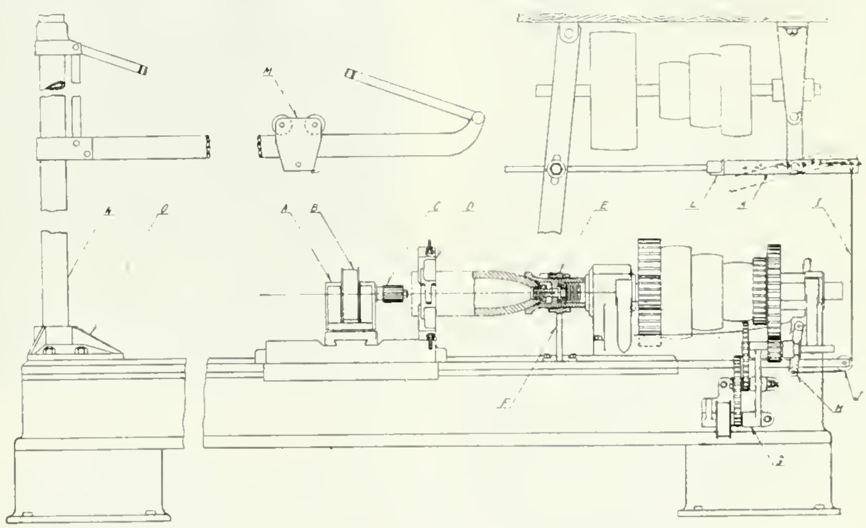

FIG. 11. BASE THREAD HOB-MILLING ARRANGEMENT.

Final Washing and Varnishing

After marking and checking for weight, the shells are given a second washing, this being accomplished by spraying the interior with wood alcohol, following which they are taken to the varnishing department for interior finishing. This process is performed in a very efficient manner, the shells being partly filled with varnish and revolved by a mechanical device to insure a thorough coating of the entire surface. Several methods were tried out, but it was found that this process more nearly approached brushing than any other, brushing being the ideal way for best results. When the varnish has been poured out the shells are placed upon another revolving device, where the threads in the nose are cleaned out with a brush dipped in alcohol, the shell revolving in a direction that will wash the surplus varnish to the outer edge.

Owing to the poor qualty of dryng medium that is now embodied in the

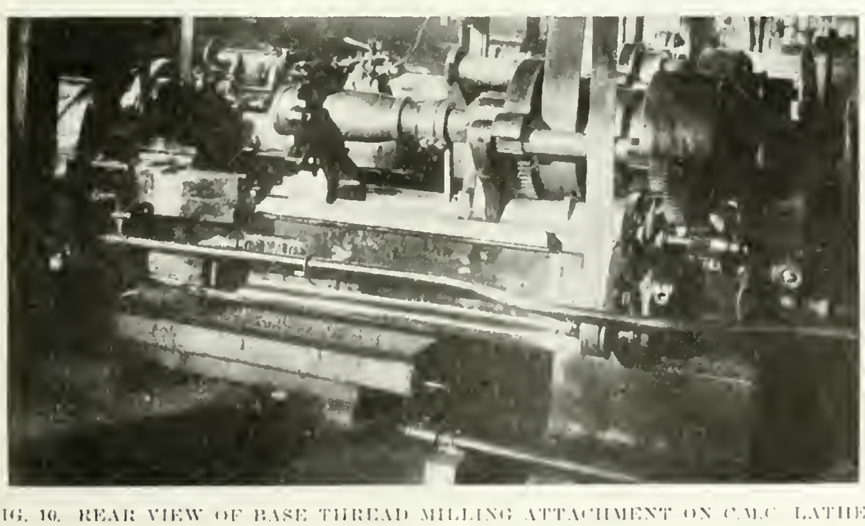

FIG. 10. REAR VIEW OF BASE THREAD MILLING ATTACHMENT ON C.M.C. LATHE.

varnish used, much difficulty has been experienced in obtaining a good permanent coating on the surface of the

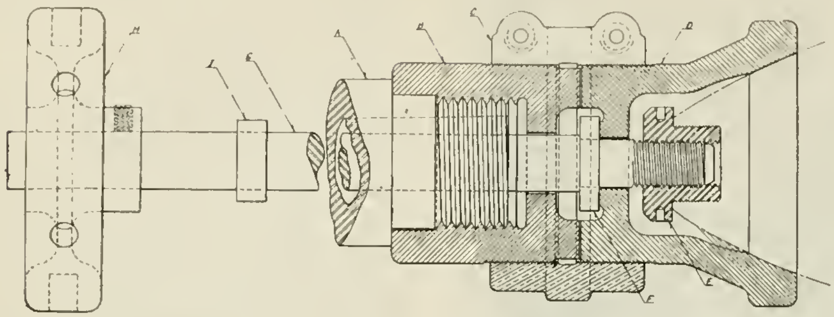

FIG. 12. ASSEMBLY OF DRIVING DEVICE FOR HOB-MILLING BASE.

shells, a tendency to flake before final setting, being apparent. Just recently, the superintendent tried out an idea, its simplicity being second only to its efficiency. The shells, after varnishing, are placed upon a truck with a small piece of tin placed in the nose and bent at an angle to deflect the air that is blown over the surface from a small fan located upon a shelf at a height of about 3 or 4 feet above the shells. By this method the drying process is completed in from twenty minutes to an hour.

Machining the Adapters

Brief mention may be made of the operations on the adapters. These consist of drilling the pin holes, rough diameter and face, rough collar, finish turn and thread, and size collar. With the exception of the finishing, the operations vary but little from other plants, and it is only the latter on which we need dwell. In common with many of the operations on the shell body, the practice of threading the adapter at the same setting as the finish turn results in greater accuracy, and avoids the possibility of eccentricity that is often apparent in other methods. Several C.M.C. lathes are fitted up for this work. After finish turning with the tools held in the ordinary tool post, the cross-slide is removed to the very front of the saddle, and the special fixture as shown in Fig. 14 is brought into a central position. This device carries a collapsible die, and is fitted with a counter-balance to maintain its alignment and assist in moving it to and from its working position.

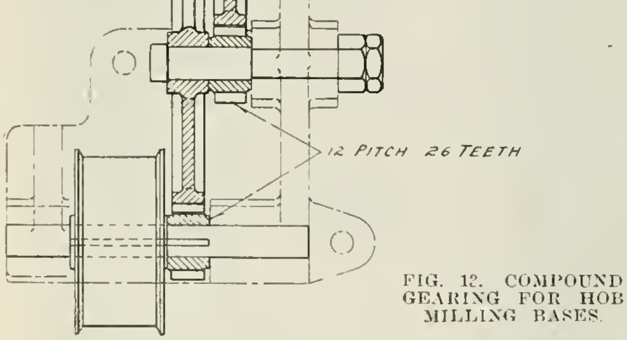

FIG. 13. COMPOUND GEARING FOR HOB MILLING BASES.

FIG. 14. SPECIAL ATTACHMENT FOR FINISHING ADAPTERS.

WOMEN EMPLOYEES IN RAILROAD SHOPS

THE C.P.R. is adding to the number of women workers at the Angus Shops, as these are required in a variety of employments. The workers have been organized by Mrs. Bell the wife of J. Bell, the superintendent of Windsor Street Station. They were carefully selected, and brought under shop regulations. They have done spendidly, and hold out the promise that women may undertake a variety of employment supposed to be the prerogative of men. The shops are turning out munitions, of course; but they are also building and repairing rolling stock, and in connection with light duties so required the women are making a good showing. The matter has now got beyond the experimental stage. Women are an economic factor to be reckoned with. They are adaptive, keen, take an interest in their work, and carry out same with vim and enthusiasm.

The Grand Trunk shops also employ women—comparatively few, so far, but the superintendent is adding to the number. By and by women will play an important economic part in the supply of transportation service in Canada.

WOMEN'S SECTION OF IMPERIAL MUNITIONS BOARD

AT the organization of the Women's Department of the Imperial Munitions Board, the services of Miss Wiseman were kindly lent by the manager of one of Toronto's largest insurance companies. However, now that the organization has been well developed, the stress of business has compelled him to claim Miss Wiseman. Her duties have now been taken over by Mrs. Frederick Fenton, who has been an able assistant to Miss Wiseman in her work.

Known to Toronto as the daughter of the late William Irving, and widow of Dr. Fenton, the new head of the Women's Section of the Imperial Munitions Board has done varied war work. Mrs. Fenton also has the benefit of the experience of a practical munition worker. For, nearly a year ago Mrs. Fenton was one of the first of Toronto's women to work in a local factory.

Grinders as Machine Tools.—Shell grinders were imported to the United States from Canada at the ports of Buffalo and St. Albans, Vt., by C. J. Tower and P. McGettrick for the account of the Ford-Smith Machine Co., Hamilton, Ont. The collectors at the ports named classified the grinders as "manufactures of metal not specially provided for," and took duty at the rate of 20 per cent. The contention of the importers, sustained by evidence, was that entry should have been given at 15 per cent. under the provision in the present tariff for "machine tools." Judge Fischer held the grinders had been shown conclusively to be "machine tools" within the generally accepted and tariff sense of the term. The protest was sustained.

Son—"Mother, can I go with pa?" Mother—"No, Willie, you are too young to listen to your father play golf."

Percussion Fuse Production with Female Labor Prominent

Staff Article

The increased production of high explosive shell has naturally created a demand for detonating fuses. To meet the exacting constructional requirements of the latter, both as to quality and quantity output, constitutes perhaps a more onerous undertaking than does that of manufacturing the various types of shell bodies. Enterprise, backed by proper organization, can, however, always win success. This is evidenced through the data following.

CONDITIONS in the metal-working industries at the present time have compelled plant owners to employ female help for all classes of service, and this is probably more pronounced in the fuse feature of munitions work than in any other, not only because of the lighter nature of the work, but also due to the fact that girls and women are, in many respects, better fitted than men for those operations where a sensitive and delicate touch are essential to economic and quality production. Such a circumstance, however, has created executive problems, involving, among others, drastic changes in the whole atmosphere associated with mechanical engineering shop practice, in order to solve the question of suitable environment for the class of help now employed. While favorable conditions may not prevail in all establishments where "diluted" labor is employed, the plant from which the following article was derived has at least put the comfort and accommodation of all its employees on the same level as that of the material production, realizing that the best in the latter respect can only be achieved under satisfactory working conditions. Owing to the tedious nature of the work, the management have provided a large rest room for the convenience of the girls, and periodical intervals of fifteen minutes each are allowed each girl in order that she may return to her place refreshed and be better fitted to perform the duties required. A large hall fitted with wash-basins and cloak lockers, has also been installed. As accidents are incidental to machine shop work, the firm have equipped a small room with every facility for "First Aid" service, a trained nurse being in charge continuously.

FULLY EQUIPPED "FIRST AID" DEPARTMENT

Machining the Lower End

The first machining operation is performed on several New Britain, 5-spindle automatics. Work progresses on four spindles at one time, while the fifth is free to remove the finished piece and insert a rough casting. The round of the turret is completed every half minute and a fair average production from each machine may be taken as about 120 per hour. The portion of the fuse machined at this setting is the lower end that screws into the nose of the shell. The cycle of operations is:—Chucking on the first, or top spindle; the second spindle being tooled to rough-off the four surfaces, outer and inner diameters, face and platform. The third spindle tools finish the above portions and also cut the platform recess; the fourth spindle cuts the recess at the base of the inside bore, while the fifth and last stage is to cut the threads on the inner and outer diameters. This last operation is accomplished with collapsible taps and dies, both being gripped in the one turret holder. The machining on this portion of the fuse is completed at four strokes of the turret spindle, and after the four spindles are in operation, a casting is inserted and a finished piece removed at each movement of the turret spindle.

Each fuse is carefully gauged and examined by inspectors as it is taken from the machine; one inspector being placed at each machine and being held accountable for all the work passing through his hands. To prevent the misunderstanding that often results from verbal instruction, each inspector is furnished with a typewritten sheet covering the specific directions that govern his work of examination. The first gauging is that of the cone length on the underside of the platform, to see that sufficient stock remains for the following operation. The length of the screw from the platform seat to the lower face must be

FIG. 1—"NEW BRITAIN" AUTOMATICS ON FIRST OPERATIONS.

between 1.155 inches and 1.145 inches. The angle of the platform is very important; a perfect angle is desirable, favoring the bearing of the gauge on the outer edge. The gauging of the thread is done with a ring gauge which must be a good fit; thread must be parallel, but not required to go to the shoulder. The 1.99- inch snap gauge must not pass over any part of the thread, as the exact size is obtained on a subsequent hand-sizing operation. The neutral depth to the shoulder of the adapter recess should be .450 inch, with a tolerance either way of .005 inch; the width of the recess at the base of the adapter chamber being .071 inch, with a diameter not greater than 1.39 inches. Care is required in gauging inaccessible parts in order that chips, etc., do not give a false reading. Indicating calliper gauges are used to measure diameter of recess. The low limit plug gauge must not enter the adapter thread, this being sized at a later stage. The fuse is also gauged for overall length to insure cleaning up on following operation. In addition to actual gauging, inspectors are required to examine for visible irregularities; the platform must be perfectly smooth without any signs of chatter marks; threads must be clean cut and free from roughness, and burrs left from tools must be eliminated.

Defective fuses are discarded and recorded as early as possible, and doubtful cases are decided by the chief inspector. Each inspector is provided with an identification stamp, which he puts upon all fuses that pass through his hands and forwards to the next operation. By this method a check is kept upon the work of each individual inspector. Defect forms are filled out each day by all inspectors, recording the number of fuses rejected and the reasons for so doing.

Drilling and Tapping Adapter Screw Hole

This operation is accomplished on a double spindle Henry & Wright drill, fitted with a swivel jig and a modern tapping attachment. The jig on this drill, and also others where two operations are performed at the one setting, are arranged to swing from a pivot pin in the table located at an equal distance from the projected centre of each spindle. Following this operation the large threads are sized by hand tapping. Collapsible taps are used for the purpose, being secured to the bench. The dies and taps are each fitted with a very efficient device for maintaining the fuses in the correct position, so as to avoid any possibility of crossing the thread when starting in the die. This attachment consists of an inserted bush placed in the bore of the chuck; slots being cut to permit jaws operating and to allow bush to protrude above the surface to a height sufficient to allow platform to rest on the top. This guiding bush is forced upwards by means of a spring, and the vertical action eliminates all chances of crossed threads.

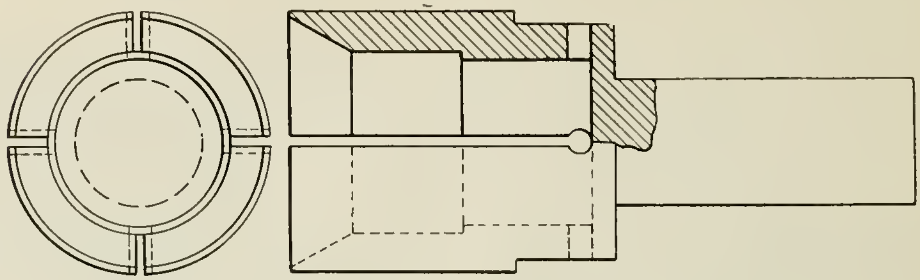

FIG. 3. SPRING HOLDER FOR PLACING FUSE IN CHUCK

Machining the Cone Portion

The machining on the cone portion of the fuse is performed on Stecher turrets, several of which are installed for the purpose, Fig. 2 showing one of these in operation. The sequence of detail machining consists of rough turning the cone, spotting, finish cone, serrations and groove, and lastly, ream and face. The roughing cut over the surface of the cone is done with a single point tool held in a slide at the desired angle of 19 degrees and 35 minutes with the axle of the fuse. This tool slide is operated by a bar held in the face of the turret, the bar acting on a roller secured to the tool block. After spotting, which consists of drilling a short distance into the nose, the cone is finished with a broad nose tool, at the same time cutting in the serrations and groove. The next operation is to drill the hole completely through and enlarge the outer portion. The hole is finally reamed slightly smaller than the finished dimension. The end is also faced at this setting, the overall length to be 2.6 inches, a tolerance of .006 inch being permitted above or below. As the central hole is subsequently reamed, the low limit gauge must not enter. It might be here stated that all working or shop gauges are made within the limits of the check gauges, and while greater accuracy is required while work is in progress, the rejections from Government inspection are materially reduced.

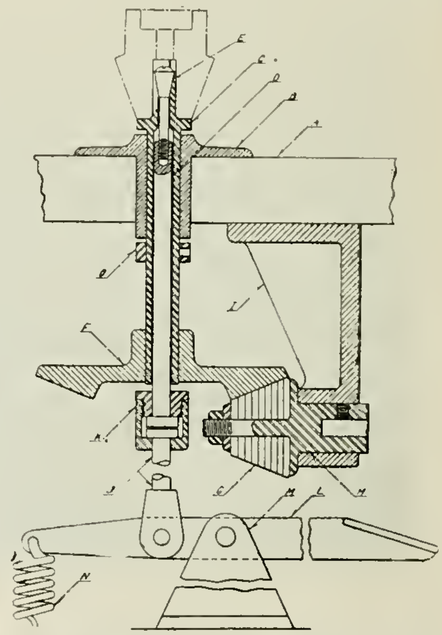

FIG. 4. DEVICE FOR REMOVING BURR FROM EDGE OF PLATFORM.

A noteworthy feature in connection with the body finishing operations is the method adopted for placing the semi-finished fuses in the pneumatic chucks on the Stecher machines. For economic production it is essential that the machine be operated continuously, and as it is a dangerous practice to place rough pieces in a rapidly moving chuck, the simple device shown in Fig. 3 is used. This is a piece of mild steel machined out to fit the rough nose of the

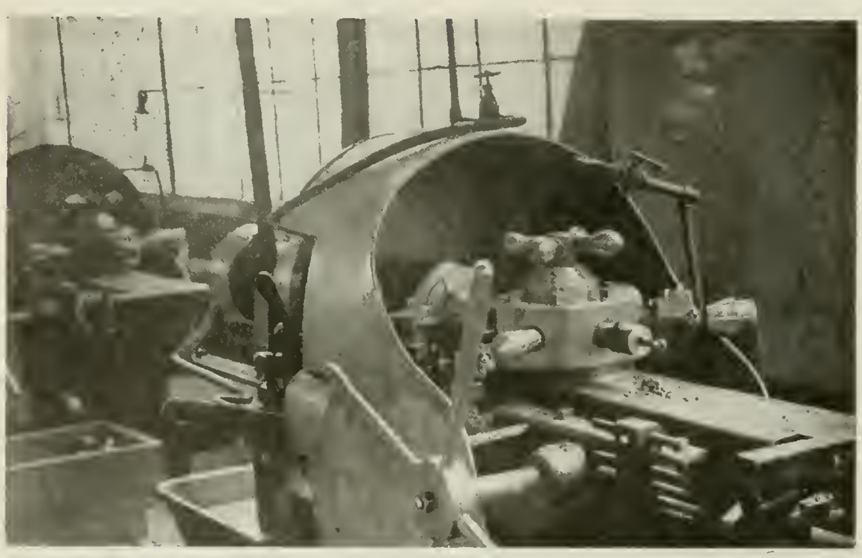

FIG. 2. STECHER TURRETS FINISHING FUSE BODIES.

fuse, with four slots cut in to serve as a spring grip; the shank being turned to fit the hole in the turret. Fuses are removed from the chuck by releasing the pressure when the finishing reamer is in the hole. The gauging instructions for inspectors on these machines are issued in printed form and are as exacting as those previously mentioned. The neutral diameter of the outer extremity of the platform is 2.387 inches, with an allowable variation either way of .013 inch. The depth of the pellet hole is very important, the tolerance permitted being only .010 inch in a length of 1.5 inches. The thickness of the lip below the groove must be between .03 and .04 inch.

Removing Burr from Edge of Platform

The slight burr at the outer diameter of the platform, which is unavoidably caused by machining, must be removed, for which purpose the machine shown in Fig. 4 has been developed. Speed of handling parts is an important factor in the manufacture of fuses, in which connection the rapidity of action of this machine is a commendable feature. Inserted in the bench is the bronze bush B, through which the vertical spindle C passes. The upper end of this tool steel spindle is turned to fit the pellet hole of fuse, and three slots are cut in to give it the expansion qualities. The action of this delicate chuck is controlled by the treadle rod D, and the tapered bolt E. Secured to the lower end of the vertical spindle is the large friction gear F, which is driven by means of the small pinion G, made of leather washers and placed on the short shaft H, which is supported by the bracket hanging from the lower surface of the bench. The treadle rod is so constructed that the lower portion remains stationary while the upper section revolves, the connection being by means of the point collar K. It will be noticed that the device is designed so that the force required to expand the chuck and revolve the work is derived from the weight of the gear and spindle, and the tension of the spring N. This arrangement eliminates the possibility of too great a pressure being put upon the split chuck, which would arise if the treadle rod were depressed by means of the foot lever.

Detail Operations

While the detonating fuses may not be as complex as the time fuses, many of the details require an equal degree of accuracy, both as regards machining and gauging of the various parts. With the exception of the foregoing operations, the bulk of the work on the fuses is accomplished on vertical drill presses, equipped with jigs or fixtures for specific operations. A row of these machines, single and double, Henry & Wright, are shown in Fig. 5. Drilling the detent hole and counterboring for tap is performed on a double spindle drill, both these operations being done at the one setting, the jig being pivoted to bring the hole central below each drill spindle. The detent hole, having a high limit of .223 inch and a low of .217 inch, is drilled to a depth not exceeding 1.425 inches from the bottom of the adapter recess, the exact depth being determined at a later stage. The counterbore for tap has a maximum depth of .205 inch, measured from the same base as the detent hole, the low limit being 0.010 inch.

The next machine, a single spindle drill, is used for drilling the small hole for the detent spindle. The point at the bottom of the detent hole acts as a guide for the small drill, which must leave the diameter between .082 and .088 inch, and have the same axial line as the larger portion. The jig used for this operation is shown at A, Fig. 6, while the other views of this figure show the application of the same design to the various requirements of the different details. At B is illustrated the jig adapted for tapping the detent hole, a small pin being placed in the anvil to locate the fuse in the correct position. At C is shown the jig arranged for connterboring the cap recess, while D is that for tapping the detent hole. The elevation of the anvil is obtained by means of a helical cam operated by a horizontal lever, and it will be noted that gauging positions are all located at points from which the inspectors gauge for finished dimensions.

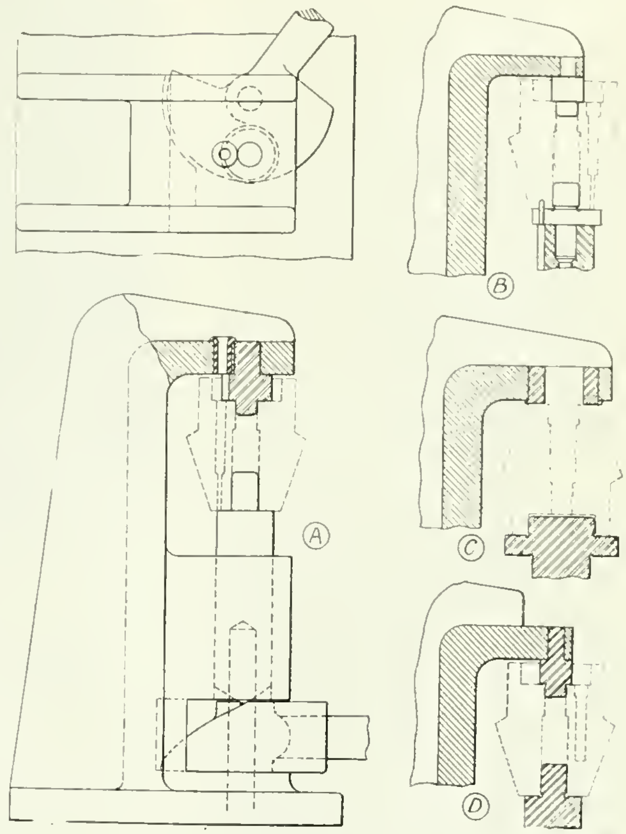

FIG. 6. FIXTURE FOR DRILLING AND COUNTERBORING FUSE HOLES.

Counterboring Detent Hole

Another jig used for counterboring the detent hole is shown in Fig. 7, the action being similar with the exception that the motion of the anvil is obtained from the vertically operated lever C, the anvil B being of fairly large diameter to protect the moving shaft from falling cuttings.

The graze pellet hole is now reamed to the finished diameter, which must be between .535 and .54 inch; and by means of a milling cutter secured to the reamer, the fuse is faced off to the exact

FIG. 5. BATTERY OF "HENRY & WRIGHT" DRILLS ON BODY DETAIL OPERATIONS.

overall dimension. The lower end of the detent hole is squared off to form a seat for the detent, and also to form a shoulder that will not fail to lock the detent

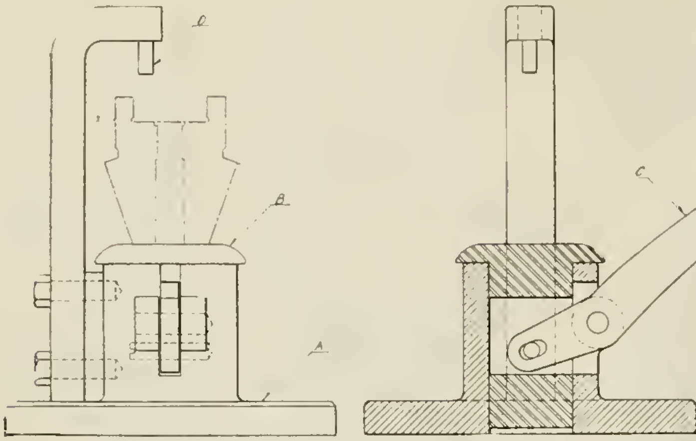

FIG. 7. FIXTURE FOR COUNTERBORING DETENT HOLE.

spindle when in action. The wrench hole is next drilled, the dimensions to be a diameter of .235 inch with a high and low tolerance of .005 inch; the depth of the hole not to exceed .38 inch at the shallowest portion. The centre of this hole must be between 1.13 and 1.15 inches from the upper or nose end of the fuse. The recess for the brass washer is the next operation, and a tolerance of .005 inch is allowed on a maximum diameter of .56 inch. The same tolerance is permitted on the depth, which must not exceed .085 inch. Following this operation the fuses are passed to another jig on the same double spindle drill, where the undercut at the base of the cap recess is cut in. A special tool has been designed for this work, where the small cutter is contained in a holder and is lowered to the proper position, being gauged by a collar resting on the nose of the fuse. As the drill spindle continues downwards, the tool is forced outwards by a taper attachment contained in the body of the fixture and acting behind the tool. Jigs similar to those illustrated in Fig. 6 are used for the purpose of holding the fuses.

It may be stated here that while the drawing specifies recesses at the base of the small screw holes, an optional method is permitted, by which the undercut may be omitted, and a screw with a pilot used to overcome the portion at the bottom of the hole that cannot be cut to a full thread.

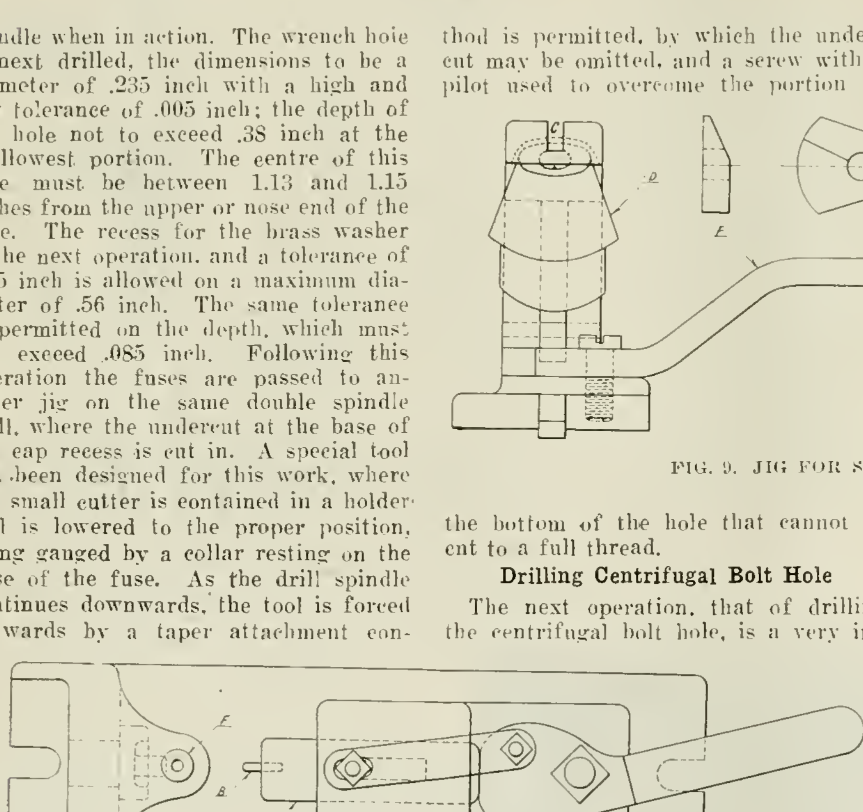

FIG. 8. JIG FOR DRILLING CENTRIFUGAL BOLT HOLE.

Drilling Centrifugal Bolt Hole

The next operation, that of drilling the centrifugal bolt hole, is a very important one, owing to its position in the fuse and the duties it is called upon to perform. The jig for the purpose is shown in Fig. 8, and is used on a two-spindle Henry & Wright drill. It is swiveled in the same manner as those previously described; the drilling of the bolt hole, which is .208 inch diameter, having a tolerance of .003 inch either way, is performed on one spindle, while the counterbore is accomplished on the adjacent spindle. The depth of the counterbore measured at the shallow portion must not exceed .205 inch, the neutral distance being .2 inch. The clamping spindle A, of the jig is provided with a locating pin B, that enters the detent hole of the fuse, the clamping spindle being guided by the key bolt C. The spindle is advanced by swinging the cam lever D and is returned by the link E. Owing to the angle at which the drill must enter the work, the guide bush F is beveled to provide better support for the drill when starting. Extreme care is exercised in having the hole accurate, jig and gauges are therefore checked daily.

Tapping Cap Recess

Tapping the cap recess and also the small plug holes at the entrance to the detent and centrifugal bolt holes is accomplished much in the same manner as the adapter set screw hole described at an earlier period. The minimum diameter of the cap screw thread, 24 to the inch, R. H., is .6 inch, with a tolerance above this dimension of .003 inch. The plug holes have a similar tolerance on a mean diameter of .3 inch. A feature that might be mentioned here is the method of handling the fuses as they progress through the shop. The drilling machines on the detail operations are so arranged that the fuses are passed from one girl to the next, often without the necessity of putting it down, although pocket trays are located between each machine in which the fuses may be placed. These trays are made of wood to avoid injury to the semi-finished work while in transit.

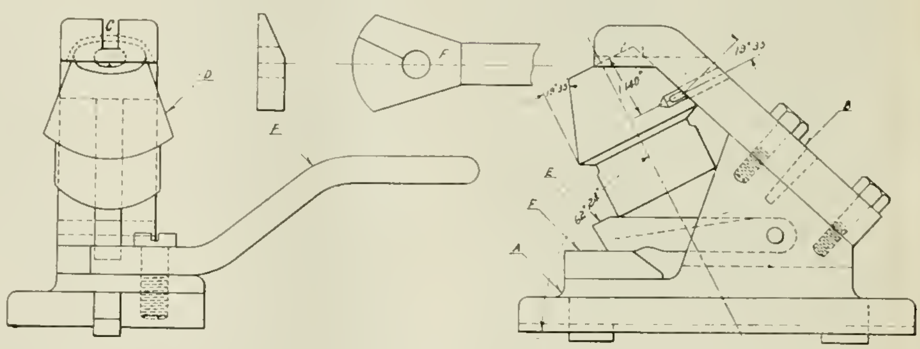

FIG. 9. JIG FOR SLOTTING FUSE NOSES.

The small angular groove at the outer edge of the nose is next milled-in. The purpose of this detail is to lock the cap in position after final assembling. Cutting this small groove is accomplished on a Whitney milling machine, the jig used being shown in Fig. 9. To the base of the jig, which is secured in a permanent position to the table of the milling machine, is secured the piece B, the upper portion acting as a locating point and also as a guide for the cutter, which

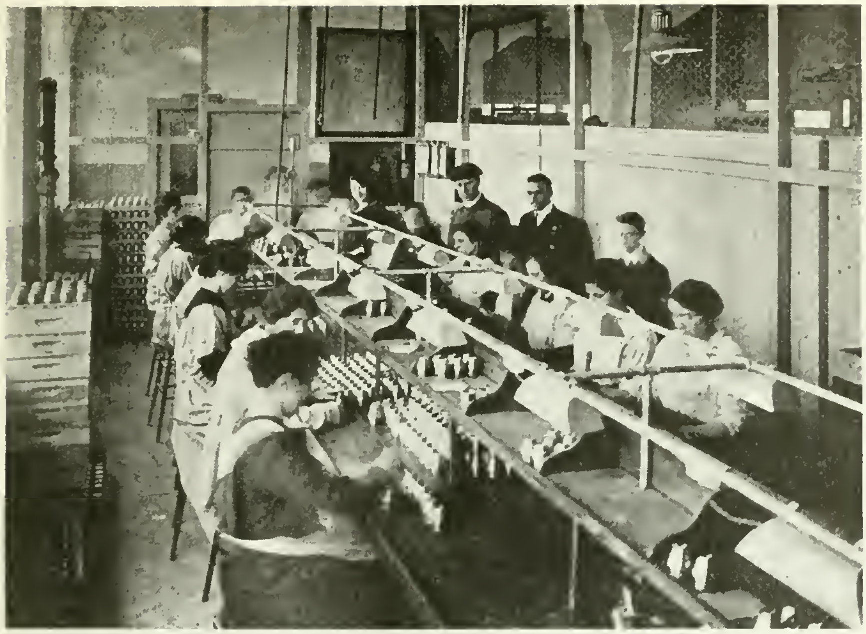

FIG. 10. FINAL INSPECTION ON FUSE BODIES.

operates through the groove C. The position of the groove in the fuse is determined by placing the wrench hole on the pin shown. The fuse is locked to a working position by the swing clamp E, acted on by the cam lever F.

Marking the Fuses

A Dwight-Slate marking machine is used to put the identification marks on the fuse, these being rolled in just below the serrations. After the fuses have been buffed and polished, they are washed and otherwise made ready for final inspection.

A view of the final inspection on the fuse bodies is shown in Fig. 10. This room is closed off from the rest of the workshop and no one is allowed in unless their duties demand it. The girls are arranged along either side of the table and gauging is under the direct supervision of several inspectors. Every facility has been provided for the rapid and accurate gauging of the various details. In addition to the pleasing environment, the chief inspector and his assistants are ever on the alert to devise methods to minimize the labor necessary in the handling of thousands of pieces each day. As an example of the ingenuity displayed in developing rapid production fixtures, the sketch, Fig. 11, illustrates a device designed by the chief inspector which greatly facilitates the gauging of the threads on the shell end of the fuse. This arrangement has materially reduced the physical exertion that would otherwise be required if the gauges were screwed on by hand.

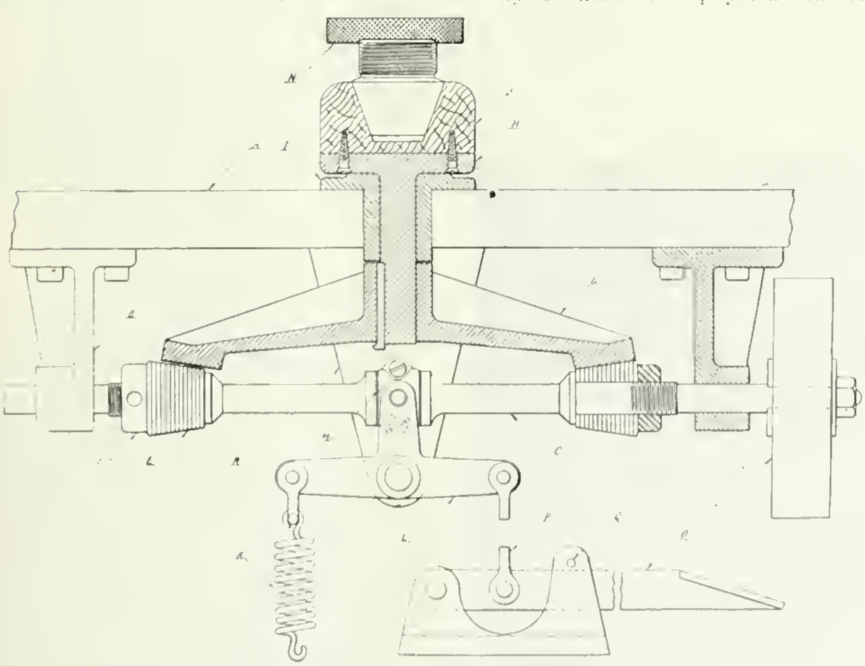

FIG. 11. GAUGING MACHINE FOR FUSE THREADS.

The driving shaft C, driven by the pulley D, is supported by the hanging brackets B. The two built-up leather pinions E, are located an equal distance on either side of the centre of the fixture. Secured to the lower end of the vertical shaft is the large friction gear G, the upper flanged end H carrying the wooden friction chuck block J; the whole revolving in the bush I. The tension of the spring K, operating on the double end bell crank lever L, causes the shaft C to be forced to the left, thus bringing right hand pinion in contact with the large gear and revolving fuse in a right hand direction. The gauge N is started on by hand, and is then placed in the block, when the ring threads its way to the platform of the fuse. Should the ring, for any reason, fail to go to the desired position, the fuse will slip in the block, thus preventing seizing of the gauge. The action of the spring will always revolve the spindle in the one direction, but, if it be necessary to stop the machine the treadle can be locked in a neutral position by means of a pin inserted in the hole Q. While the gauging of these parts is not strenuous work, much of the irksomeness has been removed by the use of this device.

Owing to the high degree of accuracy that is required, the best of lighting is essential for inspection purposes. The room is provided with spacious windows and artificial light is arranged to minimize the eye strain, the beams being reflected on the work, while the eyes of the operators are protected from the direct rays of the lamps.

Detail of Fuse Parts

Before passing to the assembling room it might be well to give a brief description of the various details, as shown in the assembly, Fig. 14. At A is seen the graze pellet that carries the detonator. This piece has an overall length of .97 inch and a maximum body diameter of .53 inch. The upper end has two shoulders, one for the locking position and the upper as a seat for the creep spring. At B is shown the centrifugal bolt, the maximum dimensions being .202 inch diameter and .245 inch long. The detent spindle is shown at C, and the container at D, the overall length of both being .65 inch; the mean diameter of spindle is .076 inch, and that of the container .2125 inch. The detent spring E is made from steel piano wire .026 inch diameter, and must contain 13¼ coils in a length of between 1.3 and 1.15 inches, after 12 hours of complete compression. This spring must compress to a length of .45 inch under a weight of 6 lbs. 8 oz. The graze pellet plug H, secures the detonator in position; its diameter being .215 inch, with the exception of the thread which is .298 inches in diameter and 24 threads per inch. The creep spring I retains the graze pellet in position after the centrifugal bolt has been displaced, and until the shell strikes an object. The action of the mechanism will be described later. This spring is made of steel piano wire .02 inch diameter, there being 6½ coils in a length of .99 inch; the spring must compress to a length of .48 inch under a weight of

$9\frac{1}{2}$ oz. The cap J fits on the nose and contains the striking needle. The cap has an overall length of .9 inch, measured from the edge of the counterbored hole, the length of threaded portion being .35 inch. The steel striking needle K is probably one of the details that is given the greatest attention as regards gauging for length, which must not exceed .76 inch from the shoulder of the head to the striking point. In fitting these needles in the caps, special care has to be exercised in assembly, and, to emphasize the fact to the girl operators, a special notice is posted above the bench calling attention to the fact that all needles must be screwed in tightly and in no case must they be eased back in order that gauge may fit, because a loose needle may have serious results to those in charge of the firing operations. At L is a distance piece made of pressed paper, and at M is a small brass washer. At N is the adapter containing the magazine Y. The details X and Y are placed at the filling base and do not enter into the manufacturing contract.

Detonator and Magazine

The detonator X consists of a small cylinder made of copper .022 inch thick, with an external maximum diameter of .225 inch, the hole in the upper end being .1 inch in diameter, and that on the bottom .05 inch. A copper washer .022 inch thick is placed inside the upper surface, and below it a thin brass disc, .022 inch thick; on the inner bottom there is also a brass disc .001 inch in thickness and between the two brass washers is contained the 1.7 grains of detonating composition. The magazine Y may be fitted with or without delay as desired, and consists of a .01 inch disc of delay composition (pressed 400 pounds dead load), contained between a perforated powder pellet and a brass fitment, these being located centrally in a tin cup of .82 inch diameter, and .26 inch deep. On the inner bottom of this cup is a thin white paper disc, and on the outside a muslin disc. On the outer upper surface is a tycoon paper disc covered with a lasting cloth washer, the whole being shellaced together and to the tin cup. The intervening space is filled with 25 to 30 grains of F. G. powder.

FIG. 13. VIEWS OF FUSE AND ITS COMPONENT PARTS.

Assembling Department

Fig. 12 is a general view of the assembling department, and the layout and method adopted is an interesting feature of the plant, being as it is an efficient factor in the rapid assembly and inspection of the various fuse parts. The girl operators and men inspectors are arranged along one side of a long table, the fuses being passed from one girl to another, each having her allotted duties to perform in the progressive assembling of the numerous parts. The fuses are placed in small pocket trays, each holding six fuses, these being moved from one operation to the next as each detail is performed, the movement being continuous. The table is divided into two sections, and at the end of each division the empty trays are placed on inclined runways and returned to the starting point. The continuous nature of the operations is such that several spare girls are required for relief purposes. The sequence of operations as the fuses advance along the bench are indicated on the general assembly, Fig. 14, in alphabetical order:—

A.—Boy filling trays and dropping in graze pellets.

B.—Putting in centrifugal bolt.

C.—Putting in detent spindle and container.

D.—

E.—Putting in detent spring.

F.—Screwing in detent plug.

G.—Screwing in centrifugal bolt plug.

H.—Screwing in pellet plug.

I.—Placing in creep spring.

J.—Screwing in cap. (Steel needle fitted in in another department).

L.—Putting in paper cylinder.

M.—Putting in brass washer.

N.—Putting in adapter.

O.—Screwing in adapter plug or set screw.

These set screws are screwed in by means of a simple jig that holds the fuse in a certain position with the screw opposite a fixed crank-operated screw driver. Two small, weighted lever bench presses are used to stencil the Lot Number, and Government Acceptance Stamp.

Before passing to the lacquer preparation table, the fuses are carefully examined by shop inspectors. After lacquering, they are given a final Government inspection preparatory to packing. Minor repairs are made at this time, but where fuse assembly does not conform to specifications, they are placed in separate cases and taken to another department for overhauling and correcting. It might be mentioned that, at various points along the assembly bench, Government inspectors are placed to check

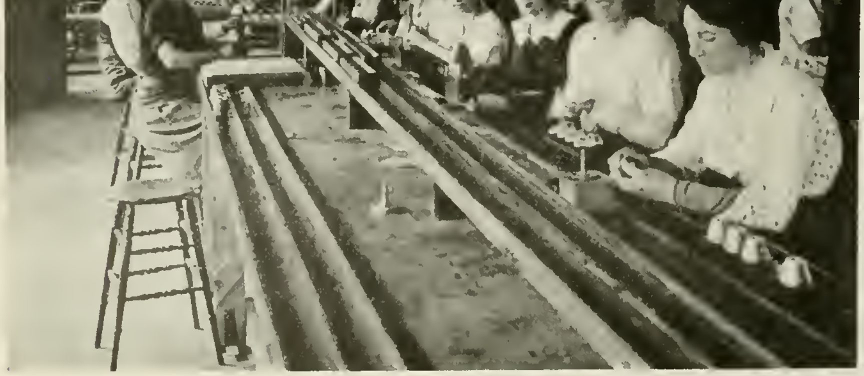

FIG. 12. FUSE ASSEMBLY DEPARTMENT.

the work as it progresses. It has been found, however, that with the close working limits that are in vogue in the actual evolution of the finished fuse body the percentage of rejected fuses is remarkably low. In this respect, it might be well to add that manufacturers in many instances, obtain the various small details from outside sources. In order, therefore, to eliminate the possibility of subsequent error, every component part used in the fuse construction, is carefully gauged and examined before going to the assembling department. Several views of the semi-finished fuse, together with the small details, are shown in Fig. 13, while Fig. 14 gives the more important dimensions and also shows a cross section of the fuse through the centre of the graze pellet and detent holes. Fig. 15 illustrates some of the gauges that are indispensable for accurate production. The group here shown is understood to cost well over $5,000, the large one in the background costing over $200.

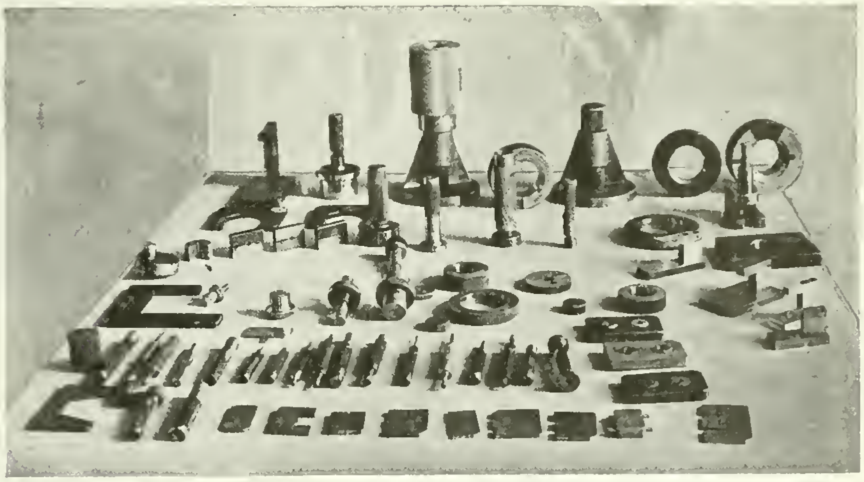

FIG. 15. SOME OF THE GAUGES USED TO SECURE ACCURACY IN PRODUCTION.

Mechanism in Action

The purpose of the various details may be better understood by a brief description of the action under firing conditions. With the fuse is assembled, the detonator cannot be fired until the graze pellet is released. In order to do this the centrifugal bolt must be removed from its position on the shoulder of the graze pellet, and, to do this, the detent must be forced down into the space now occupied by the detent spring. When the shell is discharged from the gun, the sudden and violent movement causes the small detent C and D to exert a pressure of over 25 lbs. upon the spring E, and consequently compresses it until the detent spindle is below the shoulder, when the revolving motion of the shell created by its passage through the rifled barrel, results in the point of the detent spindle tipping over to the outer edge; the reaction of the spring causes the detent to lock, thus preventing it again entering the small hole. As soon as the detent spindle has unlocked the small bolt B, the centrifugal action has the effect of making the centrifugal bolt fly out, leaving the graze pellet free to advance. As long as the shell is flying through space, however, and more especially when falling downwards, the graze pellet is prevented from creeping by the action of the small spring I. Immediately the nose of the shell strikes an object, the graze pellet will bound forward and the detonator, coming in violent contact, fires the charge, which is then transmitted either instantaneously or by means of the delay, to the explosive charge in the shell

BRITAIN'S EXPORT TRADE

DESPITE the unrestricted German submarine warfare, Britain's exports to America during the month of February show a considerable increase over those of February a year ago. During February, 1917, exports from London to America reached the aggregate of $14,061,276, as against $12,371,166 for February, 1916, an increase of $1,690,110. In January this year there was also an increase over the same month a year ago. Exports in 1917 were $16,911,008, as against $16,455,973 in January, 1916, or $455,035 more. Exports for January and February this year from London to America aggregate $30,972,284, as against $28,827,139 in th esame months last year, an increase of $2,145,145. The figures are those of exports going out of England through London alone; there is of course a considerable export going direct from Liverpool and other ports without touching London.

Of exports in two months this year from London, the biggest item is rubber, of which $10,000,000 worth was sent to America after being received from Africa and other British rubber producing parts. Art exports, including paintings aggregated $1,904,400 during Januar ' February this year, as against $1,259,087 in January and February last year.

ENGINEERS ORGANIZE FOR NATIONAL SERVICE

ENGINEERS and technical men generally belonging to the various branches of the profession in Ontario have recently organized to lend their practical and technical knowledge in the service of their country. A joint committee is making a canvass to register engineering ability of every sort and description, and cards have been distributed to the members of all the societies, asking for accurate information as to each man's special experience and qualifications.

The object of the committee is to devise ways and means by which engineers and other technical men may, as a result of their special training and experience, render assistance in the development and government of our Dominion. The immediate aim is to evolve a plan or plans whereby such of these men as for business, family, or other reasons, are unable to go to the front, may be used for war purposes at home in such manner as their special technical training may make them most valuable.

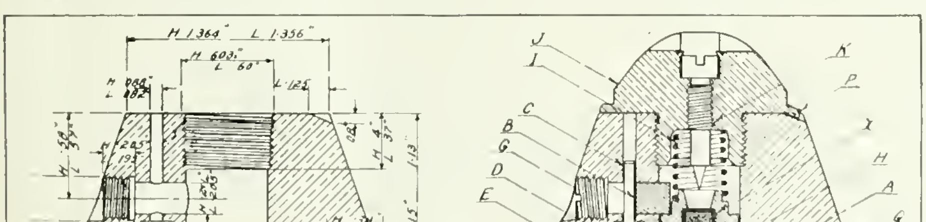

FIG. 14. DETAIL OF FUSE BODY AND GENERAL ASSEMBLY.

OUR MINERAL AND FOREST RESOURCES

THE Dominion Royal Commission now closing the fifth year of its existence has recently issued what is understood to be its final report. Along with the latter appears the fifth interim report, the subject of which is Canada, and concerning the ownership of whose mineral resources the following statement is made:—

The Commission finds it regrettable that Canada's mineral assets should be owned so largely outside the Empire, and adds that the present income received by the various Provincial Governments for the loss of their mineral wealth—a most valuable and everwasting asset, appears wholly inadequate. The taxation is quite insufficient in comparison, for instance, with that levied in the Union of South Africa.

Forest Assets

The forest resources of Canada, the Commission admits, undoubtedly form one of the most valuable assets of the Empire. It doubts whether the provincial and federal forest reserves are as yet under an efficient and economic administration worthy of the vast natural wealth which they represent. It is pointed out that Canada is estimated to have between two and three hundred million acres of commercial timber, but the output is approximately only that of Germany, where timber is cut on an area of 24,000,000 acres only. The German output however, is from lands which have taken a hundred years to bring to their present perfection, as timber producers.

"The possession of assets such as the Canadian asbestos and nickel resources could be used by the British Empire as a powerful means of economic defence. We desire to point out that, though Canada is practically the only producer of raw asbestos on a large scale in the world, the United Kingdom is largely dependent on foreign sources, especially the United States, for the manufactured asbestos which it requires."

The commission emphasizes the fact that the water powers of Canada should place the Dominion in a favorable position for the production of synthetic nitrogen compounds, while the manufacture of potash from felspar by a hydro-electrical process in Canada is contemplated.

Empire Resources Development

"The success of the action achieved during the war suggests that it is expedient that the various Governments of the Empire should take steps as soon as conditions permit," says the report, "to secure the development and utilization of their natural wealth on a well-considered scheme directed towards a definite and recognized object. In our opinion it is vital that the Empire should, so far as is possible, be placed in a position which would enable it to resist any pressure which a foreign power or group of powers could exercise in time of peace or during war in virtue of a control of raw materials and commodities essential for the well-being of the Empire and it is towards the attainment of this object that co-ordinated effort should be directed."

The commission has made a survey of the natural resources, commercial and industrial effort, and man-power of the Empire, and advocates the completion and continuance of the work under a permanent Imperial Development Board representing all parts of the Dominions which should keep this survey up to date, so that there may be a scientific development of the natural resources of the Empire.

QUESTIONS AND ANSWERS RELATING TO MUNITIONS

Question.—What is the purpose of the serrations on the forward portion of the copper bands on the large size shells?

Answer.—The guns from which these shells are fired are generally discharged at a considerable angle, the guns being brought to a horiontal position for reloading. When the shell is placed in the breech it is given a violent push forward and the serrations in the copper band provide a better means of starting the band in the rifling of the barrel, so that the hold thus attained will support the weight of the shell when the gun is tilted upward.

* * *

Question.—An air cylinder 10 inches in diameter is used to feed the saddle of a lathe when drilling a shell nose. If the gauge registers 70 lbs., what thrust is put upon the lathe spindle, provided 2 per cent. is used to move the saddle?

Answer.—The total force acting on the piston would be represented by the initial pressure multiplied by the area in square inches, or $70 \times 10 \times 10 \times .7854$ equals 5497.88 lbs. As this includes the force required to move the saddle, the net pressure acting on the lathe spindle will be 98 per cent. of the total, or 5497.8 lbs. $\times$ .98, equals 5,388 lbs.

* * *

Question.—What dead weight would be required for an accumulator to exert a pressure of 1,000 lbs. per square inch, the piston being 12 inches in diameter?

Answer.—The area of the piston upon which the pressure would come will be the diameter squared multiplied by .7854, or $12 \times 12 \times .7854$ equals 113.098 inches, and as each square inch must be subjected to a pressure of 1,000 lbs. per square inch, the weight required will be 1,000 lbs. multiplied by 113,098, or 113,098 lbs., which will be approximately 57 tons.

* * *

Question.—What rule can be applied to calculate the amount of stock to be removed from the base of a six-inch shell, when the same is overweight?

Answer.—A fairly accurate formula for calculating the weight of round steel per foot of length is to divide the square of four times the diameter by 6. Thus for 6-in. steel the weight would be $\frac{(4\ D)^2}{6} = \frac{(4 \times 6)^2}{6} = 96$ lbs. per foot. To find the weight by sixty-fourths of an inch, divide 96 by the number of sixty-fourths contained in one foot, or 96 divided by 768 equals ⅛ of a pound, or 2 ounces. Therefore, each two ounces would correspond to a cut of 1-64 inch from the surface of the base.

* * *

Question.—If the inner and outer walls of a shell were not concentric, what effect would it have on the flight of the projectile?

Answer.—The fact that a shell in flight has two distinct motions, that of the path of the projectile and the rotating motion about its own axis, requires that the closest attention be given to the production of a perfectly uniform shell to insure the highest degree of accuracy result. Should the walls of a shell vary in thickness on the same circumference, the weight would be unevenly distributed, and the centrifugal force set up by the rotating action would cause the shell to travel in ever-increasing spirals in the course of its flight. The principle is similar to the unbalanced pulley on a rapidly revolving shaft.

* * *

Question.—Why are the threads on the base plugs or adapters cut left hand, while those on the sockets are cut right hand?

Answer.—In order to increase accuracy of fire, all modern guns have rifled barrels; that is, a series of helical grooves running throughout the entire length, so that when a shell is discharged the copper band cuts its way through, causing the shell to rotate about its own axis at a very great speed. Unless the adapters were screwed in the base in the contrary direction to the action of the shell when in flight, the possibility of turning out would be very great, more especially if the adapter were a little loose. With a left hand thread, this danger is eliminated. It is, therefore obvious that all threads forward of the driving unit (the copper band), will be right hand and those to the rear will be the contrary.

* * *

Question.—Why are the copper bands on the large shells heated before being pressed in the grooves?

Answer.—In order to overcome the inertia of the mass of the shell, together with the important duty that is required of these bands when the shells are discharged from the gun, it is essential that no slippage take place between the shell and the copper band; it is therefore necessary to heat the larger sizes to insure the metal being forced well about the waved ridges and into the undercut. The contraction of the metal when cooling, also aids in the copper taking a firmer grip of the shell.

Shrapnel Shell Manufacture

Featured by An Installation of Special Equipment

Staff Article

Whether in the matter of forging or that of machining, it can truthfully be said that the various stages of shrapnel shell production continue to provide unusual scope for the display of inventive genius and mechanical engineering skill of a very high order. That the latter have not been lacking in the past, we know, and that their further development may be looked for in the future, will, we are sure, be a reasonable conclusion to anticipate.

SUITABLE equipment is undoubtedly the chief essential to the economic manufacture of any product, be same large or small, heavy or light, rugged or delicate, and irrespective of purpose or service. This fact has been amply demonstrated during the past two years. The demand for munitions necessitated the development of certain lines of machinery, to cope with the unprecedented situation created and to solve successfully problems that were entirely new to the metal-working industries of this country. Volumes would be required to relate what has taken place since the inception of shell-making in Canada, but it is safe to say that the knowledge obtained from the participation in the work will fundamentally revolutionize manufacturing methods in many branches of metal-working enterprise. The inability to secure machinery when most needed has probably been the chief reason why so many plants have been forced to make the most use of their available resources, adapting them to achieve what at one time might have been considered impossible. Full scope has been given the inventive genius of those in charge of production, and the resultant fruits have more than met the expectations of the different executives concerned.

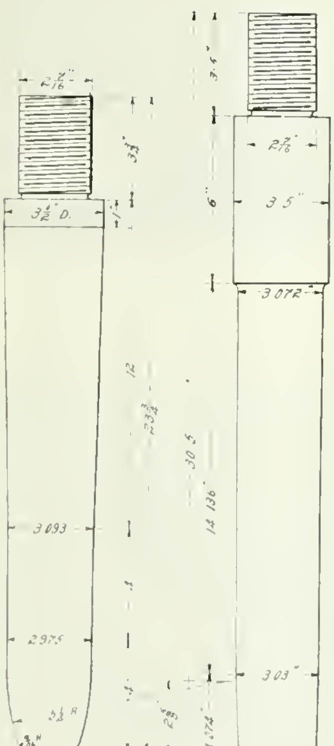

FIG. 1. PIERCING AND DRAWING PUNCHES FOR FORGING SHRAPNEL.

Shell Body Forging

Maximum production of modern munitions of war depend in great measure upon the quality of forgings that are supplied to the manufacturer. In the early period of the war, at a time when little was known regarding the technical or practical side of shell making, the equipment for the purpose was designed more from impromptu need than from any extensive knowledge of previous practice. Experience, however, together with a comprehensive study of the detail requirements has placed the manufacture of shells on a par with other lines of industrial activity, and while the product has varied but little during the past two or three years, the details of production have undergone many changes, with the result that present methods and practice, evolved out of previous faults and failures, have materially reduced the losses incidental to the work.

With due consideration given to the quality of steel used, the successful production of shell forgings is as much a question of trained labor as a problem of working equipment. This does not mean that a thorough technical knowledge is required, or even desired, by those men employed on the forging process; but each man should so study his particular duties, whether it is heating the billets, cooling the punches, or other apparently insignificant operation, that his eye and his hand shall become so trained, that he will quickly see and readily adapt himself to the needs of the situation, and thus co-operate with his other associates in attaining and maintaining maximum efficiency, both in quality and quantity.

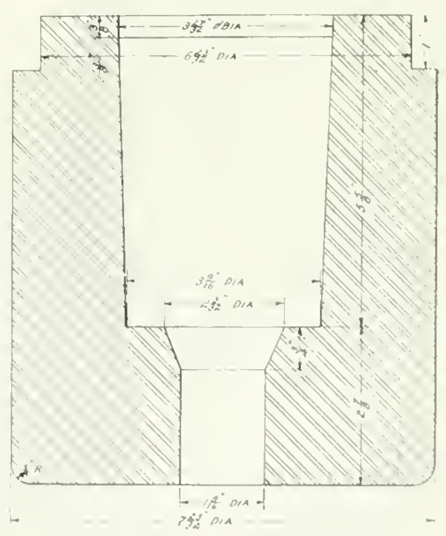

FIG. 2. KNOCK-OUT PROVISION FOR PIERCED BLANK.

Without actually seeing the process through which the steel passes, in its short but rapid passage from the bar to the rough forging, little conception can be had of the tremendous energy required on the part of the operators, in the performance of their various duties. Every section of the forging department, from cutting-off the billets to the stacking of the finished forgings, could be compared to a busy bee colony, where each individual has his allotted

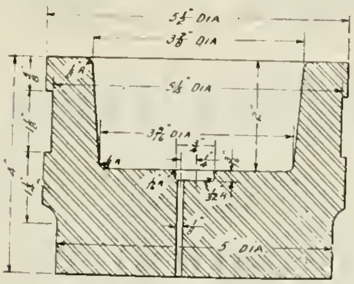

FIG. 3. CUP FORMING DIE WITH TIT.

task to perform, the end being achieved entirely free from disorder or confusion.

The gradual improvement shown in shrapnel shell production in the plant supplying the following data, has resulted from closely studying the varied requirements; and designing the dies and punches to produce a more uniform forging both in shape and dimensions. The cut billets, $5\frac{1}{4}$ inches in length, and $3\frac{1}{2}$ inches in diameter, are placed in several Mechanical Engineering Co. furnaces where they are heated to a temperature of approximately 1800 degs. F. The care exercised at this stage has much to do with the accuracy of subsequent machining operations. The uniform heating of the billets being largely a question of the trained eye, experienced heaters are indispensable, and under no consideration should this work be placed in the hands of a novice.

The first operation on the press is piercing the billet. This is accomplished on a Boomer & Boschert 250 ton hydraulic press fitted with twin dies and punches, so that two shells are operated on at one stroke. In addition to the duplex arrangement, the stroke of the ram has been reduced to eliminate the

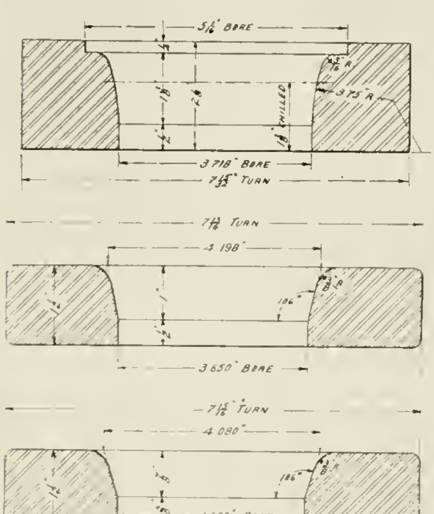

FIG. 4. SERIES OF DRAWING DIES.

loss contingent to the unnecessary lift. The actual piercing operation consists of forcing the punch into the billet and causing the metal to flow up and around the punch to a height of about 7 inches. with a slight taper on the outside surface, the base being 3 9-16 inches diameter, and the upper end 3 27-32 inches.

Punch and Die Features

The piercing punch, shown on the left of Fig. 1, has an overall length of 20 inches from the face of the descending ram. From a tangential point, $2\frac{5}{8}$ inches from the nose, the profile of the punch is formed with a radius of $5\frac{1}{4}$ inches, the extreme nose being rounded to 9-16 inch radius. From the tangential point to a distance 4 inches from the nose, the punch has a parallel diameter of 2.975 inches. With the exception Fig. 4. The top die is made of cast iron, chilled to height of $1\frac{3}{8}$ inches from the lower surface. The drawing diameter on the upper die is 3.718 inches, and has a parallel length of $\frac{1}{2}$ inch, the mouth being belled out with a radius of 3.75 inches. The center die made of machine steel hardened, has a drawing diameter of 3.65 inches, parallel for $\frac{1}{2}$ inch, the upper portion having a taper of 14 degrees with the axis of the dies. The lower die has a similar taper but with a parallel portion $\frac{5}{8}$ inch long and a diameter of 3.6 inches. The draw punch shown to the right of Fig. 1 has an overall length of 27 inches, exclusive

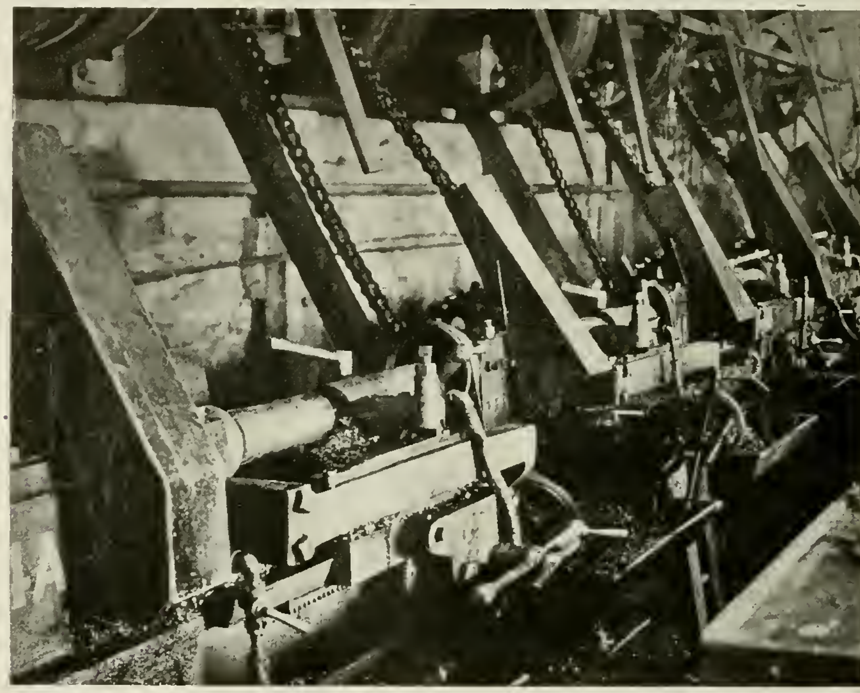

FIG. 5. "LYMBURNER" SPECIAL LATHES ON ROUGH TURNING OPERATION.

of an inch at the upper end, which is parallel, the remainder of the punch has a gradual taper to $3\frac{1}{2}$ inches in diameter, the size 8 inches from the nose being 3.039 inches diameter. As shown in Fig. 2 provision is made for a knockout to eject the pierced blank.

As the blanks lose very little of their heat during this piercing process, they are immediately transferred to the drawing press which is likewise fitted with twin equipment. The first operation is to form the cup recess at the base of the bore. The die shown in Fig. 3 is placed in a recess on the upper surface of the top draw die; when the blanks are placed in this small pot die, the punch descends and forms the rough powder cup chamber. While the general practice is to form the base of these shells flat, a small tit having a diameter of $\frac{3}{4}$ inch and a length of 3-16 inch, is often pressed on to reduce the thickness of stock at the base. A small hole is drilled through the die to permit the escape of air.

The ram is again elevated and the blanks placed in the draw dies, when the drawing punch forces the shell completely through the three dies shown in of the threaded end. This extreme length is necessary in order to force the rough shell completely through the die. As very little machining is done on the upper end of the shrapnel bore, the dimensions of the draw punch should be fairly accurate, with shrinkage allowance. The cup forming tit has a diameter of 2.16 inches, with a corner radius of $\frac{1}{2}$ inch and a length of .89 inches; it is flared out to a diameter of 2.46 inches to a point 1.1 inches from the nose. Three sections of varying tapers make up the remainder of the length, the diameters and points of intersection being 2.8 inches at 2.79 inches from the nose: 3.03 inches at 6.864 inches from the nose, and a diameter of 3.073 inches at a point 6 inches from the face of the ram.

After the shells are taken from below the press, they are gauged for concentricity and overall length and then stamped by the inspector, following which they are left to cool preparatory to being machined.

Shell Body Machining

The methods adopted in the plant from which this article has been secured, show clearly to what extent standard machine tool equipment has been eliminated, being replaced by single purpose machines which make for more rapid production of 18-pdr. shrapnel shells. In describing the manufacturing methods of this shop it is not intended to follow in detail the progressive stages, but to dwell more particularly upon those features that have been locally developed and that make for efficiency and maximum output.

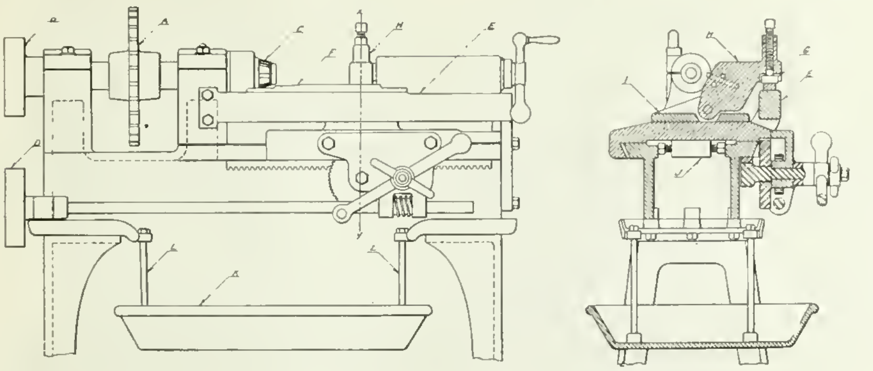

FIG. 6. DETAIL OF SPECIAL ROUGH TURNING LATHES.

Cutting Off and Rough Turning

Cutting off the open end—the first operation—is performed on special machines constructed in the plant. These machines were designed with a view to maximum of efficiency, being equipped with pneumatic chucks and automatic ejectors. The mechanism of the operating arrangement is so constructed as to put a pull upon the piston and connecting rods, this method giving greater satisfaction, as the rods being in tension provide increased holding power to the jaws. After the open end has been cut off and the chuck released, the shell is partly forced out by means of the automatic spring ejector. The length from the inner base to the open end, after cutting off, is 9 inches. Following this operation, the base end of the forging is centered in the lathe, after which the shells are rough turned on the outer diameter. Several single purpose machines of Lymburner make are used for this operation, a group being shown in Fig. 5. It will be noted that the general use of belt driven machines has been almost entirely discarded, the majority of the lathes being equipped with Baldwin chain drives, and, in order to avoid the necessity of long chains, a special countershaft has been erected about midway between the line shaft and the machines. This additional shaft, which runs continually, is equipped with tight and loose pulleys for each machine, the driving sprocket for the chain belt being rigidly secured to the side of the loose pulley. The chain drive for machines working on operations that require the constant application of oil or cutting lubricant, has an advantage over the leather or cotton belt, inasmuch as the efficiency of the drive is not affected by becoming saturated with the liquid used for lubricating the cutting tools; as a matter of fact, the chain will often do better work when well coated with oil or grease. Owing to the increased hazard contingent to the use of chain belts, special guards are installed upon all machines so equipped, in order to protect the operators. These turning machines are arranged to work in pairs, one performing the roughing, while its companion is used for the finishing operation. When roughing the outside, the main portion of the body is turned to a diameter of 3.4 inches, the minimum diameter being .01 inch smaller. One cut is required on each machine, the size of the body and the larger diameter at the mouth being derived by the action of the rocking tool post bracket upon the generating cam which is shown at the front of the lathe, straddling the saddle, and secured to the head-stock at one end, and to the end of the lathe at the other.

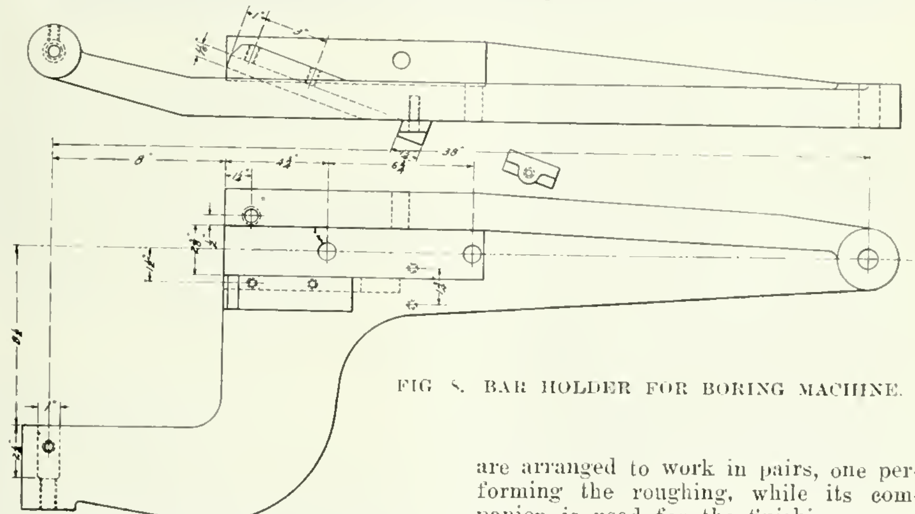

FIG. 8. BAR HOLDER FOR BORING MACHINE.

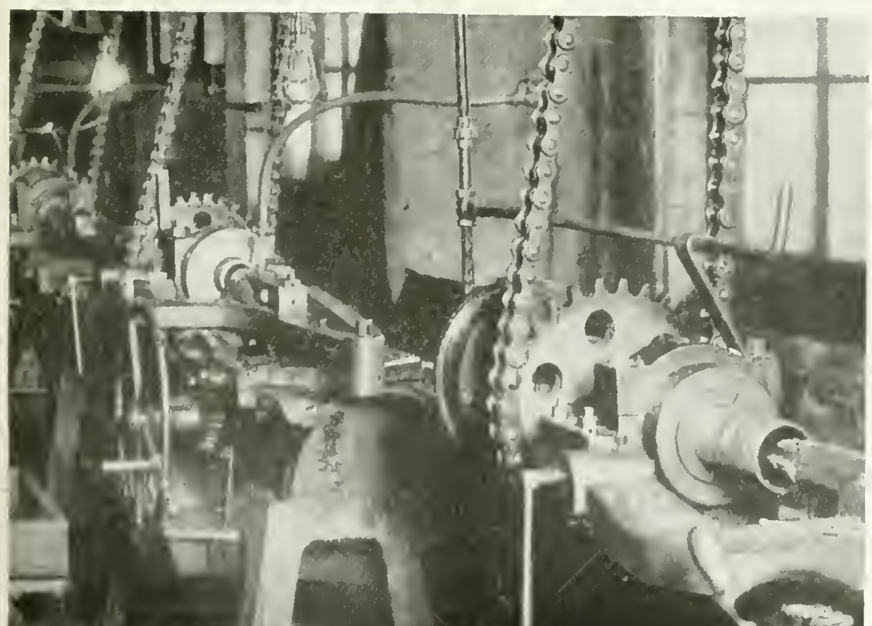

FIG. 7. INTERIOR BORING ON "LYMBURNER" SPECIAL MACHINES EQUIPPED WITH WITH "BALDWIN" CHAIN DRIVE.

Rough Turning Lathe Features

A sketch of these special lathes is shown in Fig. 6, and a casual glance will show the simplicity together with the efficient design for specific operations. The main driving unit or sprocket A is secured to the solid spindle between the two bearings; powerful yet elastic feed drive being obtained by using large diameter and wide face pulleys. Secured to the nose of the spindle is the cone-shaped, inserted serrated tooth driving arbor C. Upon the upper surface of the cam bracket E, which is secured to the stationary parts of the lathe, is the generating cam F, upon which the steel block G bears while the tool is advancing along the shell. The tool block proper is secured to the casting I by means

FIG. 9. "LYMBURNER" SPECIAL LATHES OPERATING ON WAVES AND GROOVE.

of two trunnions, one on either side. When the tool has been set ready for cutting, close adjustment is obtained by setting the screw in the tool block H. Adjustment of the tailstock is provided for by the lug J, which extends below and between the shears of the lathe. All machines are equipped with drip pans hung below the bed, from which the lubricant is drained to a central well to be again pumped to an overhead supply tank. The dimensions after finish turning are a maximum diameter of 3.32 inches, with a low limit of 3.315 inches. For a distance of ¾ inch from the open end, the diameter must be between 3.522 and 3.542 inches; the length of the taper from this point to the body diameter is 1⅝ inches. The diameter at the base to a point 8¼ inches from the open end has a neutral dimension of 3.308 inches.

Interior Boring

After the base has been rough faced, leaving a maximum thickness of .832 inches, the shells pass to the boring machines for interior machining. These tools are also of Lymburner make, being specially designed for this operation. As seen in the illustration, Fig. 7, these machines, in common with others, are equipped with chain drive, thus eliminating machine belt slippage and utilizing the full power of the line shaft belting. By referring to Fig. 8, a clearer conception can be had of the operation of the boring bar in developing the inside profile. This large movable arm forms part of the saddle, an extension of which provides a pivot for the rear end, the point being located in a central position at a distance of 38 inches from the generating point of the cam, the latter being secured to front of the forward headstock bearing. In addition to the boring bar which is held in the square groove in the centre of the fixture, a small tool is inserted in an inclined slot at one side for facing the open end at the same time that the base of the bore is being finished. The adjustment of this facing tool is accomplished by means of a small screw passing through a bracket secured to the bottom of the boring bar holder. These machines, like the turning lathes, work in pairs, roughing and finishing being performed on separate machines.

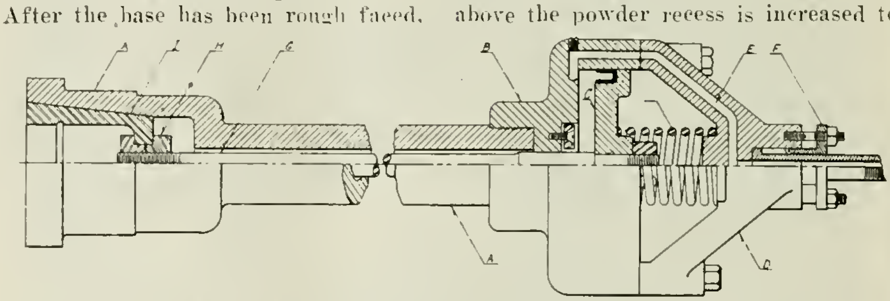

FIG. 10. AIR CHUCK EQUIPMENT OF LATHES.

FIG. 11. SPECIAL CONVEYOR IN CONNECTION WITH SHELL NOSE ANNEALING OPERATION.

Power Cup Chamber

The powder cup chamber is roughed out to a diameter of between 2.228 and 2.248 inches, with a mean depth of .870 inch. The small diameter of the tapered portion must not exceed 2.54 inches, the overall length from the open end to the inner base being 8.9 inches. The overall length, after finishing does not change, but the cup chamber is enlarged to a diameter of 2.52 inches low and 2.54 inches high, the depth to be not greater than .84 inch. The shoulder above the powder recess is increased to a diameter between 2.5975 and 2.6175 inches.

Band Wave and Groove

Before cutting the groove for the copper band, the base is again faced off to the desired thickness, which must not be less than .42 inch. Lymburner special purpose lathes are used for machining the rifling band groove, a cut of one being illustrated in Fig. 9. A fixture, forming part of the lathe, is secured to the forward portion of the head-stock, the waving attachment being in constant motion and forced into the work by the lever at the fore part of the device. The undercutting tools are in operation at the same time, they being used alternately, so that, when the waving is completed, the sides are also finished. A tolerance of .1 inch is permitted on a maximum length of .832 inch from the base to the back edge of the copper band groove.

Heat Treating

Previous to heat treating the shells, several small nicks are made with a cold chisel across the ribs in the band groove, this being considered necessary for the escape of the air from the grooves when the copper is being forced into position. The heat treatment process is similar to that described in former articles, the shells being subjected to a temperature of approximately 1,450 degs. F., care

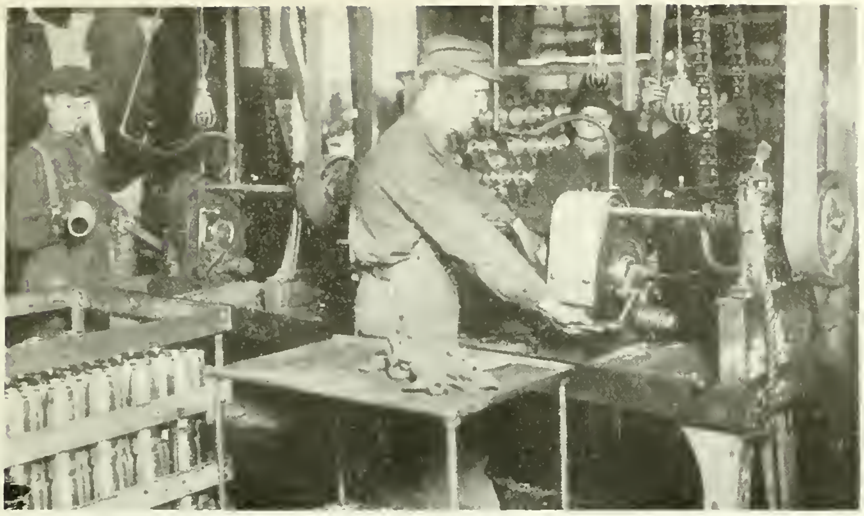

FIG. 12. "LYMBURNER" DOUBLE END CRIMPING MACHINES ROUNDING-OFF CORNERS OF SHELL BASE AND CUTTING SMALL GROOVE JUST BELOW NOSE.

being exercised to obtain an even heat on all portions of the shell. This is essential, as unevenly heated shells when hardened will show various degrees of harness when tested with the scleroscope,

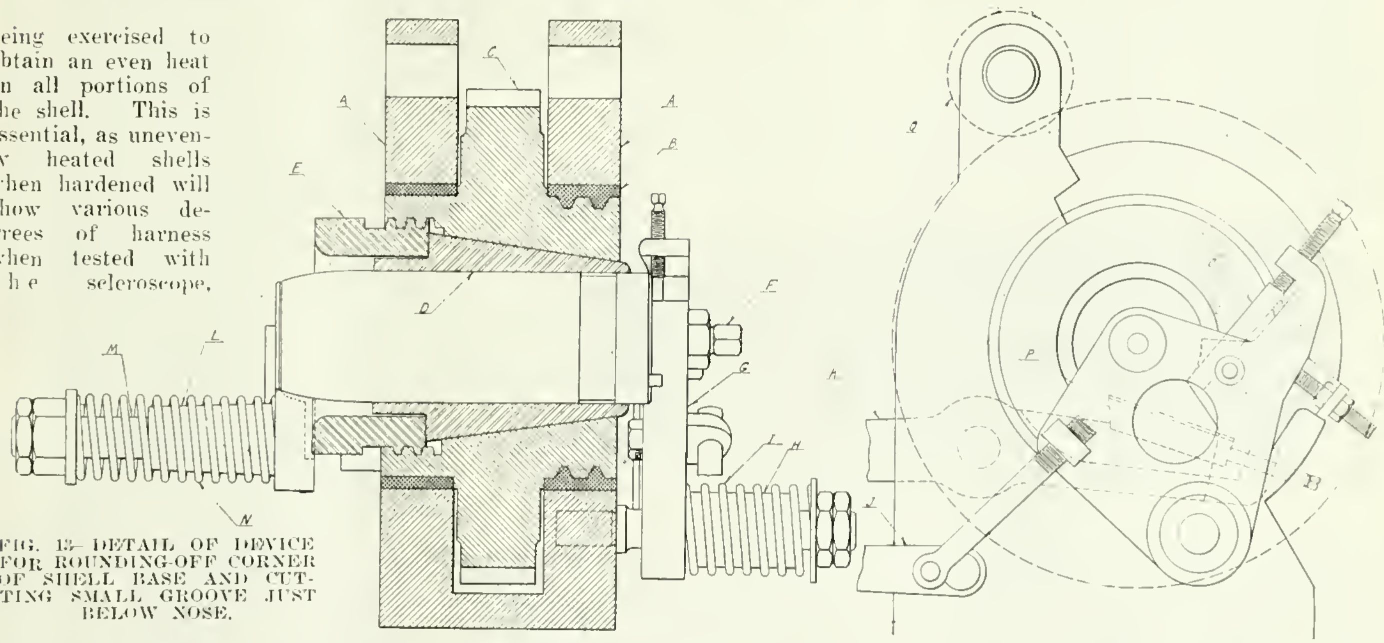

FIG. 13—DETAIL OF DEVICE FOR ROUNDING-OFF CORNER OF SHELL BASE AND CUTTING SMALL GROOVE JUST BELOW NOSE.

which in the case of shrapnel should give a reading of from 45 to 50. If above 50, the shells are again placed in the furnace and drawn back somewhat to reduce the hardness of the metal.

The medium for hardening purposes is oil which is contained in a large tank located in the centre of a still larger one, the intervening space being filled with water for cooling purposes. This water is kept in continual circulation by means of a small pump. As a certain amount of oil is removed with each shell, it is necessary to replenish the supply from time to time, and in connection with the hardening bath it may be well to draw attention to the fact that periodical inspection should be given the contents of the tank. If this practice is not followed, there is the possibility that the lower portion of the solution may consist of water that has leaked in from the cooling chamber, or otherwise; drain cocks should be provided at the lowest extremity to carry off any water that may have accumulated. Cases have been known where irregular hardening has resulted from this cause. All shells are tested with the scleroscope, after which they are sand-blasted to remove the scale created by the heating process.

Swedging-in the Nose

Swedging-in the nose is accomplished on a Brown, Boggs geared press; the shells being first heated in a lead bath, for a short distance up, to a temperature of about 1,500 degs. F. The method of heating the nose in the lead bath is necessary in order to localize the heat and avoid drawing the temper from the lower portion of the shell. As the heated shell is being placed in the press, the diaphragm is dropped in, as it is of greater diameter than the bore of the nose.

As the shells come from the swedging press, they are placed in powdered mica, nose downwards, for annealing, as it would be very difficult to machine this portion if shells were allowed to cool in the air. An interesting method has been adopted in this plant for the storage of the shells during the time required for annealing purposes. Adjacent to the nosing press, so as to avoid unnecessary handling, a special conveyor has been erected that not only offers excellent fa-

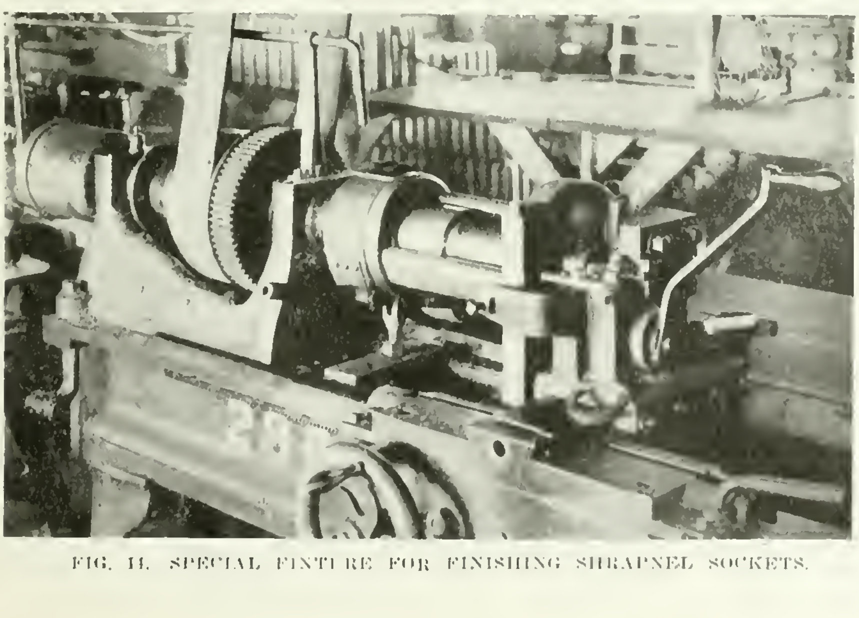

FIG. 14. SPECIAL FIXTURE FOR FINISHING SHRAPNEL SOCKETS.

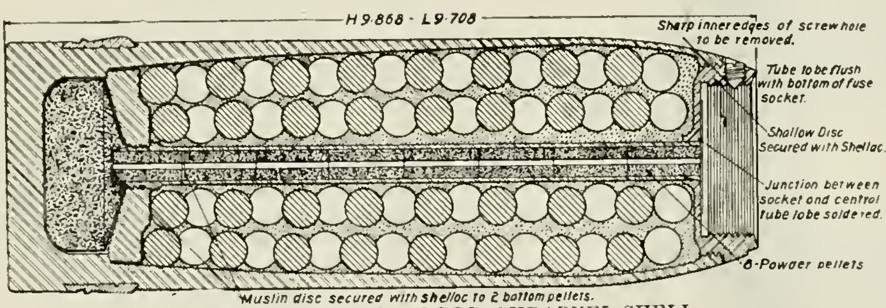
cilities for annealing the shells, but also solves the problem of additional "floor" space, which is ever an important factor in small shops. To provide ample support for the heavy weight, the structure is strongly built, provision being made for sixteen trays each holding about forty shells each. As each tray is loaded, the conveyor is moved to the next position and, when the conveyor has made one revolution, which takes 4 or 5 hours, the shells are ready to be removed from the trays. A view of this apparatus is shown in Fig. 11. As the shells are taken from the conveyor, they are placed in a small sand blast where the copper band groove is thoroughly cleaned.

Nose Machining

At present the machining of the nose is being accomplished on several Jones & Lamson turret machines, but this operation will soon be performed on special machines now under construction in the shop. The contour of the nose is formed with a radius of 6.57 inches, the tangential point being 1.91 inches back from the open end. After the inner and outer profiles have been finished and the nose threaded, the exterior surface is ground to the final shape and dimensions on a Ford-Smith grinder, several of which are installed for the purpose. After the shells have been subjected to a washing process, which is necessary to remove all grit and grease from the surfaces, the base below the rifling band groove is ground to a maximum diameter of 3.20 inches, with a low limit of 3.283 inches. It might be mentioned here that with a few exceptions, all machines fitted with chucks are equipped with pneumatic devices for more rapid and economic handling of the shells. Fig. 10 is a typical example.

Base Corner Radius

An ingenious device has been designed for rounding off the corner on the base and cutting the small groove just below the nose. Both these operations are performed at the same time, the machine being constructed so that the shell protrudes from both ends of the spindle, which is, generally speaking, simply a revolving chuck. Two of these machines are shown in Fig. 12, and their simplicity is probably one reason of their efficiency. A sectional view of the device is shown in Fig. 13. The frame which is six inches wide, has bearings seven inches in diameter made of babbit metal, one of them so constructed to serve as a thrust bearing. The "spindle" is a large cast iron gear C, which also acts as the outer portion of the chuck. The split collet D that grips the shell is operated by the nut E, the thread of which fits that on the large gear. It is obvious that with this device, it is necessary that the machine be stopped while the shell is being placed in or removed from the chuck; the adjustable stop F, acting as a gauge when placing the shell in position, this bolt passing through the arm G, which also serves as the tool holder for rounding the corner on the base end. To give increased support to this arm, it is provided with an extension H, the whole oscillating on the stud shown, which is screwed to the frame of the machine. As the gauge bolt F is kept in contact with the base of the shell by means of the spring I, any slight variation in the setting of the shell does not affect the operation, as the tool retains its relative position to the gauging point. The operation of this tool arm is obtained by lifting the lever J. Cutting the groove in the nose is similarly achieved, the position of the tool being controlled in a like manner to that on the opposite end. The driving gear ratio is 4 to 1. The groove in the nose is cut to a depth of .0175 inch and a width of .12 inch; the distance from the nose to the edge of the groove should be not greater than .07 inch, and not less than .06 inch.



TYPICAL EXAMPLE OF 18-PDR. SHRAPNEL SHELL.

The next machining operation, that of pressing on and turning the copper band, follows the preliminary inspection. Pressing on the copper band is accomplished on a 150-ton Lymburner hydraulic press, operating at a pressure of 1,500 lbs. per square inch. In order to avoid any possibility of over compression on the shell, the press is fitted with a safety relief valve located on the supply pipe. Special lathes fitted with Lymburner improved band turning attachment, are provided for machining the copper bands.

Shell Assembly

Body machining is now completed and the shells are ready for assembling. The tin powder cups are first placed in, and allowed to drop below the diaphragm, after which the brass tubes are screwed into the diaphragm and the surrounding space filled with lead bullets. In order to get the required number of bullets in the shell, it is necessary to jar the latter, this being accomplished by means of an air vibrator placed immediately beneath the spout of the hopper. This firm is at present using large quantities of these lead bullets, and, in order to conveniently handle same, a special bucket conveyor has been constructed that elevates them from a bin in the basement to the floor upon which they are used. The bullets are discharged into a large hopper above the assembling bench. While the resin is being poured in, the hole in the tube is covered to prevent any of the liquid from entering. When the desired amount has been put in, the brass socket, which has been previously coated with red lead, is screwed into position.

Applying and Machining Nose Sockets

The sockets are screwed into position by means of a mechanical device developed in the shop, a great saving being effected over the hand method. The attachment is secured to the bench so that the shell is held in a vertical position. Before the shell is placed in the chuck, a split bush is dropped over the body to allow for the greater diameter of the copper band, and when the chuck has been tightened by means of a foot treadle, a driving collar is placed on top, which engages with the dogs inserted in the body of the chuck, the fixture being revolved by a worm acting on a gear outside of the central chuck, the latter remaining stationary. As the dogs engage the driving collar, the gripping jaws are forced into the brass socket and turn it to its finished position.

After the sockets are screwed in, and the tube soldered, the shells are taken to the machine shown in Fig. 13 where the brass socket is finish turned. This machine is fitted with a special fixture for holding the shell and machining the same. The shell jig is secured to the face-plate of the lathe and has two stiff arms extending out to a circular portion that revolves in a separate steady rest. The shell is placed in the chuck from the side, between the two arms, and is secured in a working position by the action of an air operated ram forced forward by the cylinder located on the rear of the spindle. The entire machining on the socket is performed by the movement of the handle shown, the outer edge being finished as the lever is pushed outwards, while the reverse movement cuts the inner portion to the desired shape and size.

From here on, the shells are passed through the several operations of reaming and hand sizing, final inspection, painting, packing and shipping. A feature of the plant, and one that has had much to do with the successful production, is the establishment of a local shell committee, which meets periodically to study the best methods of organization for rapid and economic output.

On an examination paper the following question was asked: "What is steam?"

One engineer said: "Steam is water in terrible sweat."

OUR PRESENT EFFORTS A FUTURE ASSET

HISTORY has been made in more ways than by feats of arms since the memorable appeal for shells was made by Sir John French when in command of the British forces in France. Not the least notable of developments incident to the then crisis has been the steady increase of munitions output by Canada, with its resulting influence on our future status in the manufacturing world, and which, is yet, possible of little more than approximate estimation. One fact, however, stands out in strong relief amid the meantime din of industrial effort, viz., our reserve strength in men, money and material wealth.

In pre-war days the productive capacity of the Dominion, in strictly mechanical fields, was of a very limited nature, due in part to the fiscal policy which seems to be indispensable to young industrial nations during the embryonic stages of developing their natural resources and consolidating their commercial and manufacturing enterprises. Had times such as these been foretold in all their present reality, their improbability would have been readily admitted rather than otherwise.

In referring to the articles on munitions manufacture which feature this issue, it may be said that they in themselves are ample evidence of the first item of reserve strength, i.e., men. The use of the word "men" is, of course, somewhat ambiguous now, in view of the successful and increasing employment of women, and when we say successful, we mean more than getting out shells or fuses on time. By successful, we mean the utilization of women help in such a manner that mutual satisfaction with the results obtained will insure a future continuance whenever and wherever opportunity offers. Among the contributing factors may be mentioned equitable remuneration, facilities enabling their arrival and departure from work to be made in a manner consistent with reasonably refined custom, and the shortest hours possible that the nature of the work permits.

Another noteworthy and intensely personal factor, and perhaps more important than that of actual service, is the mechanical resourcefulness which has been displayed by the staffs of hundreds of factories from ocean to ocean. In the ordinary course of events, thousands of mechanics would never have had occasion to worry about methods and devices of production to the extent at least that these latter have had to be applied in solving satisfactorily munitions manufacturing problems. Their experience with products of their own brains and hands in competition with those of erstwhile competitors and foreign specialists has given them a confidence in their own ability and a capacity for estimating and appreciating at their true value the products of others, a circumstance in itself that cannot help but have a great, though indirect bearing on our future industrial activities.

It has enabled them and others to judge our engineering products from every angle, and, while the ultimate growth of the country precludes the possibility of being entirely independent of foreign machine tool builders, conditions during the last two years have been such that a fuller, stronger, wider, and more distinctively Canadian industry in machine tool building can be confidently looked forward to.

Vast though our expenditure on war has been, it must not be forgotten that our ability to meet this is due to national credit, which in turn is founded on national resources. Without the first and last of these—men and materials—our credit might long ago have ceased to exist. The recognition by the Government of the necessity for scientific research, and subsequent industrial development, will result in an ever-increasing appreciation of Canada's natural wealth. The extent of our dependence on the United States for essential materials would be brought home to us, perhaps more vividly, if the entrance of that nation into the European conflict resulted in prohibition or even restriction of much meantime exported material. It would, however, be ultimately beneficial so far as it stimulated the development of our own resources—mineral and manufacturing, and many present projects in these directions, especially the latter, are not likely to be abandoned without a struggle.

DEVELOPMENT OF SHIPBUILDING AND MARINE ENGINEERING

REGARDING the plans of the Imperial authorities relative to the development in Canada of shipbuilding and marine engineering, together with the auxiliary equipment incidental and necessary thereto, we are in a position to state that in at least one instance definite arrangements have now been concluded, and contracts arising therefrom placed. Immediate action is being taken regarding fulfillment of the latter. Reference was here made in our last week's issue to the fact that negotiations concerning the above had been entered upon and were making progress.

Shipbuilding and marine engineering combine an aggregation of manufacturing industries in their finished product unsurpassed by any other forms of industrial endeavor, and what is thus true in a general sense, is even more emphatically so as regards iron, steel, and the manufactures thereof. The plans now being matured will include in their scope not only our at present established ship and marine engine builders, but the establishment of others of a like nature in combination or separate. In addition, those of our engineering plants in position to undertake the building of marine boilers, propelling and auxiliary machinery—the latter ship deck or 'tween decks—are embraced in the projected developments referred to.

Taken all in all, no such opportunity has ever presented itself to Canadian business enterprise as that of shipbuilding in its variety scope, now knocking, and no such urgency either for the "Cause" or otherwise, has been so worthy of prompt consideration.

The Genera Market Condition and Tendency

THE industrial situation continues satisfactory in regard to the volume of business offering, but manufacturers are still experiencing the greatest difficulty in getting supplies of raw material, owing to the freight congestion on the railways. The shortage of coal has been relieved, but the railways so far have been unable to do much in the way of moving the large volume of freight lying in the yards at the frontier. The situation is serious and is affecting trade generally, touching both manufacturers and merchants. Receipts of coke and pig-iron at the furnaces are improving, and it is expected that the output of domestic pig-iron will increase materially in the near future. There is, however, no Canadian foundry pig-iron on the market at the present time. The situation at the foundries has improved to some extent, owing to increase in supply of raw materials. Prices of steel products continue very firm, and the general impression is that further advances are certain, notwithstanding the prevailing high level of values. This will naturally be reflected in prices of finished iron and steel goods, and, therefore, affecting many lines of machine shop supplies. While the machine tool market is not particularly active just now, business is a little better than it was earlier in the year. Canadian machine tool builders have, however, plenty of work on hand, with deliveries, if anything, rather slow. Prices are very firm and further advances on some lines of tools are anticipated. Quotations on all kinds of scrap metals are very firm, with an upward trend. The ingot metal markets continue very firm, influenced largely by the expectation of war between the United States and Germany, in which event prices would undoubtedly advance materially.

Montreal, Que., March 5.—The industrial situation has undergone little change during the week. The freight congestion is not so pronounced, but conditions as yet show little relief. The lack of fuel and other raw materials is still a feature of the situation, and no immediate relief is anticipated. Developments in the States may terminate in a crisis at any time, and predictions of daily conditions are more or less futile.

Pig Iron

That the steel situation is due for further strength is indicated in the recent sharp advance in the pig iron market. The scarcity of raw material, coupled with heavy demands, has been followed by an advance ranging from $1 to $6 per ton for various grades of American iron. Canadian producers are out of the market, having withdrawn all price quotations.

Steel

The railroad situation has experienced some relief during the week, but facilities as yet are far from adequate. Many factories are still affected by shortage of raw materials and maximum activities have not yet been generally resumed. Steel dealers locally report the conditions as increasingly serious, and anticipate still further difficulties should the States reach the breaking point with Germany. The Pittsburg quotation on billets has been advanced $5 per ton, the nominal figure being now $70. Forging billets show a similar increase, the quotation being $90 per ton. The shortage in plates is still acute, and mills are reported to be filled up until the close of the year. Higher prices are looked for in sheets. Indications point to an advance in wire products very shortly, as several producers have already withdrawn quotations, pending a readjustment. Owing to prevailing conditions, this will not come as a surprise, as this line has remained steady for some time, under adverse circumstances. Following increased demand for iron bars, the price on this commodity has been advanced $5 per ton. The local situation is practically unchanged, but dealers anticipate a tighter situation in the near future. Price changes are confined to boiler plates, these being advanced $10 per ton, the current nominal quotation being $6.50 for 1/4 to 1/2-inch plates, and $6.85 for heads.

Metals

Existing conditions all tend to increase the strength of the metal situation. The movement is generally upwards, emphasized by inability to secure delivery. Copper is very strong, but not active. Tin has again reacted upwards. Spelter is steady, but with a weaker undertone. Lead is again advancing. Antimony is firm, but developing weakness.

Copper.—The market is still influenced by the continued upward movement of prices, and buying is light. Uncertainty on all sides as to the early future seems to have developed extreme cautiousness on the part of consumers, and sales are generally being made only for immediate needs. The London market is very firm, but the nominal price on the New York market has declined 1/2c on the week, the current quotation being 36 1/2c for electrolytic and 33 1/2c for castings. Dealers here have advanced quotations 2c per lb., lake and electrolytic being 42c and castings 41c.

Tin.—While little tonnage of tin has been lost through submarine activity, the possibility is ever present, and the market is in a state of continual expectancy. Both London and New York are quoted at higher levels, the latter reporting the quotation of 53c, this being 3 5/8c higher than last week. Tin has again advanced locally, the quotation being 53 1/2c, an advance of 2 1/2c per lb.

Spelter.—Operations on the part of dealers have developed a firmer tone, but consumers have not been influenced to take an active interest in the present situation. Producers were looking forward to a return of former activity, and should this situation continue, spelter may show a weaker tendency. The American situation is very firm, with prices 1/8c above that of last week, the New York quotation being 11c per lb. Local dealers report an easier tendency, but prices firm at 15c per lb.

Lead.—Some relief has been given to the situation by the easing of the freight situation, but the scarcity of spot metal is apparently as pronounced as ever. The action of the trust in advancing their quotation to 9c has placed lead in a much stronger position. Dealers here report an advance of 1/2c on a strong market, the quotation being 13c per lb.

Antimony.—Improved transportation facilities have enabled deliveries to be made to an extent which has brought about a slight weakening in demand, with prices dropped somewhat. A decline of 3c on New York quotations has reduced the nominal price to 31c per lb. Firm locally at 34c per lb.

Aluminum.—The situation is very firm, the market showing an undertone of strength. Unchanged here at 70c per lb.

Machine Tools and Supplies

No features have developed to change the general situation, although the trade anticipates conditions in the near future that may materially affect the present tone of the situation. The serious effect that the stoppage of American shell contracts was expected to have on the Canadian situation, owing to the fact that much of he machinery would be placed here, has quieted down, and the prospect now is that very little of this equipment will find its way to Canada, as America may find itself in a position to utilize the bulk of this shell machinery. While the present business is not heavy, the outlook for the spring months is encouraging, in view of further prospective shell contracts. Sales of machinery are confined to single or small lots, and delivery on these is still delayed by existing railroad conditions.

Scrap

Increasing strength is developing in the scrap situation, and higher prices are pending. New York quotations are generally stronger, and dealers here are contemplating a readjustment. The transportation question is still serious, and difficulty is experienced in receiving and making shipments. Local changes are confined to machine compositions and turnings, the former being quoted at 23c and the latter at 19c per lb., this being an advance of 1c and 1/2c respectively.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

Toronto, Ont., March 6.—While the fuel situation has been relieved for the time being, little improvement has been noticeable as regards supplies of raw materials. The efforts of the railways were concentrated on moving coal but there still remains a large volume of freight along the frontier that has not been touched. Manufacturers who cannot get their raw materials are seriously handicapped. Machinery houses have the greatest difficulty in getting shipments through, while several cars of steel products have been over three months in transit from Pittsburgh to Toronto.

Steel

The situation in the steel trade has improved during the past week principally because supplies of coke are coming forward in greater volume. It will probably be some weeks before conditions are really satisfactory and production of steel reaches the level which obtained during the latter part of 1916. The return of cold weather will further handicap the railways and cut down supplies of fuel. Notwithstanding adverse conditions however, the steel companies are making a fine showing in regard to the production of steel for munitions. Plant extensions have of course enabled them to increase their output, to mention one concern only as a typical case. The Nova Scotia Steel & Coal Co., whose report for 1916 was recently issued. The output of forged shells in 1916 was 90 per cent. greater in number, and 120 per cent. greater in weight than in the previous year, while the total shipments of finished steel, forgings, etc. showed an increase of as much as 64 per cent.

Prices of iron and steel products continue very firm and further advances in the near future are expected. Plates, particularly, are bound to reach considerably higher levels owing to the large excess of demand over production. The mills are declining large tonnages because their capacity is quite unable to cope with the extraordinary heavy demand. The urgent demand for ships is the principal reason for the unusually tight situation in plates. Higher prices on wrought pipe are likely as skelp has recently advanced. Steel bars and shapes are unchanged, but very firm. A shortage of natural gas at Hamilton is causing considerable inconvenience at the mills.

Sheet mills continue to operate at reduced output, production ranging from about 75 to 85 per cent. of capacity owing to the unsatisfactory traffic conditions. Shut-downs are threatening all the time owing to the shortage and uncertainty of supplies of raw materials, chemicals, and fuel. Practically all mills are sold up for most of their first and second quarter output, prices are thus very firm and seem certain to avance. Galvanized sheets are already up; Premier No. 28 gauge is quoted at $7.70, and 10 3/4 oz., at $8.00 per 100 lbs., with higher prices expected.

The fuel situation in the United States is not quite so acute but is still seriously affecting production at a time when even a small falling off in output is severely felt. During February, operations at the mills equalled only 70 per cent. capacity, the falling-off in production being due to the severe cold weather and transportation difficulties. The situation has recently improved to some extent, production now being about 85 per cent. of capacity. Prices of iron and steel products continue very firm, but no important changes have been made during the week.

Pig Iron

With the freight situation improving, shipments of coke and pig iron are moving more freely. If the improvement continues with no set-back, the furnaces and foundries in this district will resume more active operations. The pig iron market is still very firm and prices steadily advancing. Very little foundry iron has been obtainable from Buffalo furnaces, but what can be secured is around $37 at furnace.

Scrap

The improvement in the freight situa-
(Con. on page 155, Advtg. Section.)

TORONTO MARKETS—Continued.

tion is welcomed by scrap dealers and business is more active. Prices continue very firm on all kinds of old material, but there are no important changes to note. There is a heavier demand for low phosphorus steel scrap, and prices are steadily stiffening. Lead scrap is very firm and an advance is looked for shortly. All grades of copper and brass scrap continue very firm at unchanged prices.

Machine Tools

The machine tool market continues fairly quiet, the general disposition being to await developments as regards further shell contracts. The business that is passing is almost entirely in connection with munitions plants. Deliveries are slow on practically all lines of machine tools with the exception of lathes which are readily obtainable. Second-hand equipment is in good supply, but the demand is light at present. Prices continue to have an upward tendency. Some firms are only quoting at the price obtaining on date of delivery. One U.S. manufacturer of milling machines has advanced his quotations 10 per cent. A Cleveland concern contemplates making an advance on milling machines and shapers.

Supplies

The general situation as regards machine shop and mill supplies has now changed materially from last week. Business continues very brisk and prices on all lines are very firm. The high cost of pig lead has naturally resulted in an advance on lead products, including lead sheets which are now 2c higher. Gasoline, benzine and coal oil have each advanced 1c per gallon, and further advances are expected during the year. There appears to be a great scarcity of linseed oil, and prices, therefore, are entirely nominal.

Metals

There is practically no change in the situation in the metal markets, and prices have been maintained at last week's level. The general tendency of the market continues strong, due for the most part to the expectation that the United States will ultimately be drawn into the war. Copper continues strong with prices still nominal. Tin although higher in London is unchanged here. Prices of tin are also nominal, the market being affected by submarine operations. Spelter and lead are firmer at unchanged quotations, while antimony is quiet and easier.

Copper.—There have been no recent developments of importance in the copper market. Spot and nearby demand has not been so active, although a fair volume of business has been done in third quarter copper. Early deliveries continue scarce, and the general aspect of the market continues to be one of waiting developments. Quotations continue nominal and unchanged at 39c per pound.

Tin.—Although the price of tin has advanced in London, local quotations are unchanged, but market is firm. Submarine activities are affecting the market although it is understood that very little tin has as yet been lost. Local quotations are nominal and unchanged at 56c per pound.

Spelter.—Supplies of spelter in the East are more plentiful, and the situation has been relieved to some extent. There is no real shortage of metal, as production is large enough to take care of the present demand. Local quotation unchanged at 14c per pound.

Lead.—The "Trust" price of lead which for some time has been below the outside market has been advanced to 9c New York. Independents, however, are still quoting 10.25c to 10.75c New York for spot metal. There has been a marked falling off in demand, but the advance is expected to stimulate business. Local quotations unchanged at $12\frac{1}{2}$ per pound.

Antimony.—The market is quieter though still firm, due to the continued scarcity of antimony. Local price 35c per pound.

Aluminum.—The market is firm with a slight upward trend but local quotations are unchanged at 68c per pound.

LATIN-AMERICAN TRADE POSSIBILITIES

THE following paragraphs, taken from the *Pan-American Union*, are descriptive of trade possibilities in Central and South America:—Broadly speaking, Latin-America is one of the new quarters of the world. It has an older culture than ours, and it would be to our advantage to study the systems of thought and law, and other things that count in life that dominate in Spanish and Portuguese America. Nevertheless, for lack of economic pressure and, until quite recently, of immigration and, because of the enormous extent of natural resources, there has been no general mastery and development of those resources. In most Latin-American countries, the people to-day are merely living on the fringe of the country, so far as natural wealth and possibilities are concerned.

The vast continent of South America, and the by no means inconsiderable territory of Central America—nor ought we to forget the Latin West Indies—offer an inviting market for the widest possible variety of our products and, indeed, for products of which we have yet produced no respectable quantity for purposes of export. The chief demand in all the Latin countries is for what we may call medical products, that is to say, for those things that are directly necessary for the protection of native raw materials. Thus everything that enters into the development of railways and transportation facilities generally is an absolute necessity for every Latin-American country whenever it sets out to develop its resources one stage further than that which it has reached. That surely should be a significant fact for the people of this country. They might long ago have taken vigorous steps to associate in the Latin-American mind all that is new and comprehensive in railroad expansion and railroad facilities with American capital and American exporters.

Rolling Stock of British Origin

At present the railroads of Argentina are owned in Engalnd, and the locomotives there have been made in Leeds. In Brazil only a small part of the rolling stock has come from the United States, and in Chile a few specimens from the Baldwin works, but for the most part the rolling stock has come from England or the continent of Europe. As in railroad development so in the industries dependent upon the production of power; everywhere power houses are being constructed in Latin-America in connection with municipal enterprises or the activities of public-service corporations. The machinery and, equally important, the fuel have largely to be supplied from abroad. The South American continent has disclosed but little fuel except, perhaps, Argentina's recently discovered petroleum, and the Colombian and Peruvian oil wells, both of which fields have not yet reached an advanced stage of development, and a certain quantity of coal in the southern part of Chile.

Demand for Manufactured Goods

There is a demand for manufactured articles of every possible and imaginable type, and, above all, those which have to do with agriculture. Uruguay, Southern Brazil, and Argentina form one of the great wheat regions of the world. The demand for sugar machinery is growing constantly in the tropical section of the continent; and the Brazilian cotton market is going to take its place some day beside that of the U.S. Southern States and of Egypt. Then, too, all the luxurious accompaniments of refined taste are in demand, and these tastes in Latin-America are in a remarkable degree to be found everywhere, and in no way inferior to those which characterize the greatest capitals of the world. The Latin-American even of moderate standing enjoys a cultivated acquaintance with the fine things of Europe—with European literature and drama, with the finest costumes that Paris and London can produce—a familiarity that is, indeed, rare in the United States. If a professional man, he is closely in touch with all that goes on in the European centres of his profession; he has the latest law books from Paris, the latest scientific instruments from Germany, and is constantly alive to all the intellectual currents of Europe. The intimacy between Latin-America and Europe is bound to create a strong demand throughout Central and South America for Articles of refinement and culture and to create there at least an excellent market.

Raw Materials in Exchange

What has Latin-America to give in return for these by no means inconsiderable demands that she makes upon the rest of the world? She can give raw products and those alone. Grain, fruit, meat, coffee, wool, hides, fine woods and dye woods, rubber, precious metals, and industrial minerals—these are the things that Latin-America has and which she proposes to exchange either for tools with which to get further supplies of raw material or for objects requisite to the ordinary carrying on of a highly organized and complex social system. Of any one of the materials mentioned, Latin-America seems to possess an inexhaustible supply, and her capacity to meet the growing requirements of the rest of the world for these things would appear to reach as far as human vision can foretell. In proportion as the necessities of transportation are met, and the difficulties of extracting and preparing for shipment or even for manufacture on the spot of these raw products, the economic wealth of Central and South America will loom larger and larger in the eyes of international economists.

Investments of Great Britain Are Prodigious

Let us see briefly how these things balance and what conditions will result. So far as Latin-America has been developed to this stage she owes it pretty much wholly to Europe. To-day, except possibly for one or two Central American Republics, the Latin-American world is dominated by Europe financially and commercially. The investments of Great Britain alone are really prodigious, amounting to fifty-one hundred millions of our money in public loans, national or local, in public-service corporations, and in banking and transportation. To some extent the vast trade that Great Britain enjoys with Latin-America is nothing more than disguised interest upon these great investments. Great Britain has come to depend upon the food products of Latin-America to such an extent that her subsidized shipping lines, which have to maintain a continuous stream of food-bearing vessels from Argentina and Uruguay to England, have always been willing to reduce the outgoing freight rates even below actual cost in order not to have the boats, which necessarily must return to South America, go out empty. That, perhaps, is the secret why the exporter from the United States has often found it cheaper to send his goods to Southampton for transmission to Latin-America than to send them direct from Boston or New York.

Banking Facilities

Moreover, European banks have been in South America in some cases for nearly a century, and they have been very strongly established for over a half century. These banks are ready to give credit, and they are so closely allied with the merchant that they are always willing to back him up and enable him to sell credit, although his main business is to sell merchandise and not credit. The power of these European financial institutions is soon realized by any man who seeks to enter a Latin-American market. This South American market is inviting, but we will have to work fairly hard to earn a share therein.

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa. British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—H. R. Poussette, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H Ross, Stock Exchange Building, Melbourne. Cable address. Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—Acting Trade Commissioner, Lonja del Commercio, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—G. B. Johnson, P. O. Box 109, Yokohoma. Cable address, Canadian.

HOLLAND—Acting Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address. Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrivskaya. Ploshch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent. Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 27-28 Pearl Building, East Paradise, Leeds. Cable address, Canadian. F. A. C. Bickerdike, Canada Chambers, 36 Spring Gardens, Manchester. Cable address, Cantracom. J. T. Lithgow, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.

SPECIAL TRADE COMMISSIONER—LUMBER

H. R. McMillan, visiting Europe, Africa, Australasia and the Orient.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin, Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum Grubbeged No. 4, Christiania, Norway. Cable address, Sontums.

CANADIAN HIGH COMMISSIONER'S OFFICE

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Guelph, Ont.—The Page Hersey Iron Tube & Lead Co., has awarded the contract for the erection of an addition to its plant to cost $3,500.

Princeton, B.C.—The Canada Copper Corporation is to erect a 2,000-ton mill here and will construct 13 miles of railroad to mines on Copper mountain. Work will cost about $2,000,000.

Coaticook, Que.—Penman's Ltd., propose to erect a power house, construct a concrete dam, and install 180 h.p. turbine and generator. Engineers, T. Pringle & Sons, Ltd., Montreal.

New Hazelton, B.C.—The Santa Maria Mine has commenced mine development at Telkwa, B.C. Machinery consisting of drills, compressors, hoists, pumps, and gas engine will be installed.

Thorold, Ont.—The Exolon Co., manufacturer of abrasive refractory materials, has commenced the erection of an addition to its plant, and will instal equipment so as to increase the production by 100 per cent.

St. Thomas, Ont.—The plant of the C. Norsworthy Co., known as the Red Foundry, was badly damaged by fire on Feb. 28. The origin of the fire is unknown. The loss, $20,000, is partly covered by insurance. The company will rebuild at once.

St. John, N.B.—It is reported here that a plan to establish a steel shipbuilding plant on the Miramichi River, in Northern New Brunswick, is being worked out. Two million dollars is said to be the capitallization. Montreal money is understood to be in the deal.

Hull, Que.—Fire which broke out in the plant of the Hull Steel and Iron Foundries Ltd., on Sunday afternoon caused damage to the extent of between $4,000 and $5,000 to the building and its contents. The loss is fully covered by insurance.

Parry Sound, Ont.—The new plant of the British Cordite Co., to be built at Parry Sound by the Canadian Explosives, Ltd., for the Imperial Munitions Board, will probably be the largest work of its kind in Canada. Orders for the material and equipment are being placed by the Canadian Explosives, Ltd., Montreal.

Haileybury, Ont.—The Riordon Pulp & Paper Co., which established a rossing plant at Haileybury two years ago, is planning to erect a large sulphite plant in the same neighborhood. Surveys for the site of a 500-ton mill are now being carried out and it is proposed to have the first unit of 100 tons ready by January. The mill, if completed to the 500-ton capacity now under consideration, would be easily the largest of its kind in Canada.

Trenton, Ont.—The Church-Ross Co., of Montreal, it is said, have taken over the contract of the Gaylord Engineering & Construction Co. here, and work in the different departments is fast nearing completion. Messrs. Fraser, Brace & Co., of Montreal have a contract for the smokeless powder plant, and have commenced operations.

Windsor, Ont.—A contract has been closed with the Canadian Steel Corporation and the Hydro-Electric Commission for two thousand horse power of Niagara current. The contract provides that the steel company shall use not less than 2,000 h.p. for the next 20 years, and after that period have the option of purchasing an additional 3,000, making 5,000 h.p. in all.

Victoria, B.C.—With a capitalization of one million dollars, the Ladysmith Smelting Corporation, has been incorporated and will operate, the old Tyee smelter at Ladysmith, which was recently purchased from English owners by United States capitalists, at the head of whom are Col. Stevenson, an Alaskan mining man, and F. A. Seiberling, head of the Goodrich Tire & Rubber Co. Offices have been opened here in the Belmont block. Additions to the plant will increase its capacity to 1000 tons per day.

MUNICIPAL

Bothwell, Ont.—The Town Council are considering installing a waterworks system.

Brantford, Ont.—The City Council are considering the question of installing pumps in connection with the water works system.

Kincardine, Ont.—The Town Council will submit a by-law shortly to provide free site for a $50,000 factory to be erected by J. B. Watson.

Hull, Que.—The city council will call tenders about May 1, for a mechanical filtration plant to cost $170,000. J. P. A. Laforest is engineer.

Caledon Township, Ont.—A by-law has been passed to raise $5,000 to provide for the cost of works, plant, machinery and appliances for the village of Alton.

London, Ont.—The City Council has decided to include in the City of London bill to be presented in the Legislature provision for the erection by the Railway Commission of a modern grain elevator at Port Stanley. It will cost about $100,000, and will assure London of at least one large new industry this year.

Sherbrooke, Que.—The City Council proposes to purchase Two Miles Falls at Weedon and to erect power plant and transmission lines to Sherbrooke, at a cost of $1,500,000. Francis & Co., Montreal, are consulting engineers.

Brantford, Ont.—Fire Chief D. J. Lewis, has recommended the purchase of the following: Combination hose and pumping auto truck, 800 gallons per minute, $10,000. Motor tractor ladder truck $5,000. Storage battery system to replace present gravity battery system $1,800.

Ottawa, Ont.—The City Council has awarded contracts for their 1917 supplies as follows:—Lead pipe and pig lead, Canada Metal Co., Toronto; castings and special pipe castings, Thos. Lawson & Sons; oils and grease, Imperial Oil Co.; cast iron pipe, National Iron Works, Toronto.

GENERAL

Montreal, Que.—The Walter M. Lowney Co., will build an addition to their factory.

Grimsby, Ont—The Metal Craft Co., have obtained a building permit to erect a factory here at a cost of about $4,000.

Toronto, Ont.—The B. J. Johnson Soap Co., have purchased a site and expect to erect a factory and warehouse to cost $50,000.

Longueuil, Que.—Mr. Bruay of the Belgian-Canadian Glass Co., is negotiating with the town regarding the building of a glass plant here.

Winnipeg, Man.—Fire last Monday destroyed the plant of the Armstrong Trading Co., with an estimated loss of between $50,000 and $75,000.

St Hyacinthe, Que.—Duclos & Payan, will build a factory for the manufacture of leather goods, etc. Ross & Macdonald, 1 Belmont street, Montreal, are the architects.

Preston, Ont. A by-law authorizing the town to endorse bonds for the Preston Car and Coach Co., to the extent of $75,000 was carried last Monday by the ratepayers.

Ottawa, Ont.—W. J. Trick's industry, known as the Oshawa Interior Fittings Works, was totally destroyed by fire early on March 1. The loss is estimated at from $75,000 to $100,00, but, it is understood, is well insured.

Oshawa, Ont—The Pre-Cast Concrete & Supply Co., have taken over the plant of the Concrete Builders Ltd., and propose to install machinery for making concrete bricks, blocks, etc. T. P. Parker of Oshawa is interested in the new concern.

Toronto, Ont.—The City Architect has issued a permit to Canadian Aeroplanes, Ltd., for a brick addition to the Fuselage factory, on the west side of Dufferin street, near Lappin to cost $25,000.

Niagara Falls, Ont.—Construction work will be started immediately on the the erection of a new plant at Niagara Falls, for the American Cyanamid Co., whose plant was recently damaged by fire to the extent of $250,000.

PERSONAL

Richard Bell, for the last twenty-three years chief engineer of the pumping station at Sarnia, Ont., died on February 19th, aged 43.

G. Gordon Gale, formerly general manager and chief engineer, Hull Electric Co., has been appointed vice-president and general manager.

John R. McDonald, who has for several years been successfully in charge of the mines of the Franco-Canadian Colleries, at Frank, B.C., has resigned.

Capt. James N. P. Ritchie, master of the C. P. R. steamer Princess Patricia, died at Victoria on Feb. 21. Capt. Ritchie was born in Yarmouth, N.S., 58 years ago.

James S. Paige, who for some time has been associated with the Fore River Shipbuilding Co., of Quincy, Mass., has been appointed general manager of the Port Arthur Shipbuilding Co.

D. Walter Munn, of the Montreal Rolling Mills Branch of the Steel Company of Canada, has joined the engineering department of the Algoma Steel Corporation, Sault Ste. Marie, Ont.

George Dawson, who has been master mechanic of the Canada Stove & Foundry Co., St. Laurent, Montreal, and who is leaving to accept a position in Campbellford, Ont., was given a farewell supper and presented with a quarter-oak cabinet and a silver tea service at the factory on Feb. 26, by his fellow-workers.

Major John Roaf Barber, president of the Barber-Ellis Co., paper dealers and envelope manufacturers of Toronto, and one of the pioneer paper manufacturers of Canada, died last Saturday at his home in Georgetown, Ont., in his 77th year, after an illness of three months. Mr. Barber had been actively connected with the Barber-Ellis Co. for over forty years, and was also president of the Wm. Barber & Bros., Georgetown, Ont. Mr. Barber was born in Georgetown in 1841.

TENDERS

London, Ont.—The County Council of Middlesex, are in the market for a 10-ton steam road roller. Tenders received until March 22. John Stuart, county clerk.

Yorkton, Sask.—Tenders are being received for the following:—One 357 h.p. oil engine, one 280 k.w. generator, one transformer down to 30 kw., 450 feet of 4-inch cast iron pipe, 200 pounds of lead. Further particulars from F. J. Pilkington, town clerk.

East Angust, Que.—Tenders for the construction of a Boys' Academy at East Angus, will be received at the secretary-treasurer's office until March 15. Plans and specifications will be seen and all informations obtained at the secretary's office at East Angus. J. E. Palmer, secretary-treasurer.

Winnipeg, Man.—Tenders will be received up to March 9, for the supply and delivery of one electrically operated, three-phase oil switch for the city's terminal station. Instructions to bidders, specifications and form of tender may be received at the office of the City Light and Power Department, 54 King street.

Ottawa, Ont.—Tenders addressed to the chairman of the Board of Control, will be received up to March 13, for the supply and delivery of: 10 roller type, single horse refuse wagons; 18 two-horse rectangular box refuse wagons; 4 two-horse bottom dump refuse wagons. Specifications and full particulars may be obtained on application to the City Engineer's office, City Hall, Ottawa.

Quebec, Que.—Tenders, addressed to the secretary-treasurer of the Municipality of Halifax-South, will be received until March 25, for the construction of two highway bridges, with steel superstructure, concrete abutments, approaches, etc., on the Fortier and Pidgeon Rivers (ten arpents distant in the Parish of St. Ferdinand d' Halifax, Megantic County. Plans and specifications may be examined at the Council's Office and at the Department of Public Works and Labor, Quebec.

INCORPORATIONS

The Thompson Powder Co., has been incorporated at Toronto with a capital of $500,000 to manufacture all kinds of explosives at Deseronto, Ont. The provisional directors are Fred C. Sutherland, Hugh H. Sutherland and Norman C. Urquhart all of Toronto.

Kingston, Ont.—The St. Lawrence Smelting & Refining Co., has been incorporated to carry on smelting and to manufacture metals of all kinds, with $100,000 capital, by Frederick H. Markey, Waldo W. Skinner, and Wilson G. Pugsley, all of Montreal, Que.

International Shipbuilding Corporation has been incorporated at Ottawa with a capital of $2,000,000 to construct and operate ships of all kinds with head office at Montreal. The incorporators are Henry A. Lovett, George W. Cole and B. F. Bowler all of Montreal.

Canadian Coal Products Engineering Ltd., has been incorporated at Ottawa with a capital of $1,250,000 to operate coal mines and manufacture coal products with head office at Toronto. The incorporators are A. J. Reid, Norman Limpricht and William Bowler all of Toronto.

Standard High Speed Steel Hardening Co., has been incorporated at Ottawa with a capital of $150,000 to carry on business as metal manufacturers, founders, machinists, etc., at Montreal. The incorporators are Anthime Fortin, Frank Willdon and Francis Guerin all of Montreal.

Canadian Rein Drive Tractors Ltd., has been incorporated at Ottawa with a capital of $1,000,000, to manufacture tractors, motors and machinery of all kinds. The head office is at Toronto and the incorporators are Henry J. Martin, Charles Evans-Lewis and Edmund H. Austin all of Toronto.

Shell-Bar Boico Supply Co., has been incorporated at Toronto with a capital of $40,000 to manufacture munitions, and tools, etc., and to take over the Shell-Bar Grate Co. and Boico Ltd. Head office is at Toronto and the provisional directors are Henry D. Lanz, George S. Moffatt and J. L. Wilson all of Toronto.

The Kingsdale Box Co., has been incorporated at Toronto with a capital of $60,000 to take over the business of lumber and woodenware business formerly carried on by Ross & Branscombe at Kingsdale Village, York County. The incorporators are William P. Gillespie, and Harry K. Bowes of Toronto and B. Ross of Newmarket, Ont.

Carbon & Alloy Steels Co., has been incorporated at Ottawa with a capital of $1,500,000 to take over the Moffatt-Irving Steel Works, Toronto and to operate a steel foundry at Hamilton, Ont. The incorporators are James B. O'Brien and James W. Moffatt of Toronto and Henry J. Waddie of Hamilton, Ont.

MARINE

Sarnia, Ont.—Capt. J. Reid has purchased the outfit cruiser Reo and will use her in connection with the reid wrecking tugs this season. The boat is 50 feet in length and fitted for long trips.

Quebec, Que.—The manager of one of the leading ship-building companies of Lauzon has just returned from New York, with a contract for the construction of fifty wooden vessels of the same style as those built last year only somewhat heavier.

Victoria, S.C.—The Norwegian steamer Strinda, Capt. Lovedahl, after undergoing extensive repairs and overhaul at Yarrows, Ltd., has left for Vancouver. The steamer, which is under charter to the C.P.R., will load a capacity cargo for Vladivostok.

Halifax, N.S.—During the past week applications were received at the Board of Trade office from two different parties for information regarding steel shipbuilding and the site available. This makes the third such application within a month.

St. John, N.B.—It is reported here that a plan to establish a steel ship-

building plant on the Miramichi River in Northern New Brunswick is being worked out. Two million dollars is said to be the capitalization. Montreal money is understood to be in the deal.

Victoria, B.C.—According to an announcement made by Captain C. H. Nicholson, manager of the G. T. P. coast steamship service, important structural altrations have been ordered for the steamer Prince John which is at present repairing at the Wallace Shipyards, North Vancouver, after her stranding in Wrangel Narrows a few weeks ago

Victoria, B C.—The C.P.R. steamer Princess Patricia, which is undergoing repairs at the plant of the Victoria Machinery Depot following her recent mishap by stranding on the Spanish Banks while on her regular run between Nanaimo and Vancouver, is expected to be ready to take the water very shortly. The work on the Patricia has proved to be bigger than was anticipated.

Vancouver, B.C.—Contracts have been let by the Dominion Government for the construction of two auxiliary schooners promised some time ago. The vessels, which will be used in the trade between Victoria, Vancouver and Halifax, via the West Indies, will cost approximately $250,000 each and the contract stipulates they must be ready for commission by September next. The vessels will be on similar lines to those now under construction for the Brown syndicate. The Wallace Shipbuilding yards at North Vancouver will build one of the vessels and the Cameron-Genoa Shipbuilders, Ltd., at Victoria, the other .

BUILDINGS

Montreal, Que.—Permission has been granted the St. Jean Baptiste School Commission to issue debentures for $275,000 to erect a school on Berri street and Chateaubriand avenue, by the Board of Catholic School Commissioners of Montreal. The school will have a frontage of 206 feet on Berri street and 220 feet on Chateaubriand.

TRADE GOSSIP

Saskatoon, Sask.—The Saskatchewan General Development Co., has been organized with a capital of $1,500,000 to build pipe lines and supply natural gas to municipalities in the province.

Montreal, Que.—The C.P.R. are building at the Angus Shops, 260 automobile cars with double decks, and specially adapted for the accomodation of motor cars during railroad transportation.

Windsor, Ont.—The signing of a contract between the local Hydro Commission and the Canadian Steel Corporation will lower the hydro rate at Windsor from $39 to $31 per horsepower.

Prohibit Export of Cyanide of Sodium.—The exportation of cyanide of sodium and compounds and mixtures containing cyanide of sodium, from Canada to countries other than the United Kingdom, British Possessions and Protectorates, has been prohibited by Order-in-Council.

G.T.R. Order Ten Engines.—The Canadian Locomotive Works, Kingston, Ont. have succeeded in closing a contract with the Grand Trunk Railway system for ten large Mikado-type locomotives.

The Cockshutt Plow Co., Brantford, Ont., are making tractor plows for the British market. Over 500 have already been shipped to the Old Country and the company have orders on hand for 400 more.

The Illinois Tool Works, Chicago, Ill., have opened an office in 403 C.P.R. Building, Yonge and King streets, Toronto, in charge of Allan B. Wearing who has been appointed Canadian representative.

Durham, Ont.—The National Portland Cement Co. is now manufacturing at its plant, near here, a considerable quantity of potash from feldspar as a by-product. The output of potash, which is being used as a fertilizer, is 14 to 16 tons per day.

Flotation Plant Reduces Loss.—The 150-ton oil flotation plant which was recently installed at the Coniagas Mine is understood to be resulting in a larger recovery than was anticipated. The loss now is said to be less than one ounce of silver to the ton.

The Canadian Fairbanks-Morse Co., Ltd., Toronto, has been awarded a contract by the City Council, of Kitchener, Ont., for a motor-driven centrifugal pump, consisting of a 25 h.p. Fairbanks-Morse motor direct connected to a Fairbanks-Morse centrifugal.

The Canadian Fairbanks-Morse Co., Ltd, Toronto, have secured a contract from the Town Council of Bothwell, Ont., consisting of a 24 h.p. oil engine, direct connected to a Goulds triplex pump for fire purposes, and a motor-driven centrifugal pump for domestic purposes.

Ontario's Heavy Fire Loss.—E. P. Heaton, Provincial Fire Marshal, addressing the Mutual Underwriters' Association, said that the fires in Ontario during the past year numbered over 8,900, with an aggregate loss of $12,000,000. This, Mr. Heaton said, was the highest fire loss in the Province in any year since the great Toronto fire.

British Shells for U.S. Navy.—It is reported that Great Britain has withdrawn her objection and given permission for Hadfields, Ltd., to contract with the United States navy for large armor-piercing shells. The withdrawal of objection by the British Government may cause the secretary to re-award the contract to Hadfields.

Toronto Man's Patriotic Gift.—Prime Minister Lloyd George has received a cablegram from David J. Johnston, Canada Nitro Products, Toronto, presenting to the nation, to aid in agricultural work, 100 farm tractors of a type considered the most efficient yet designed. The gift includes harrows, binders and other implements. A skilled mechanic will accompany each tractor. Lloyd George replied gratefully accepting the generous gift on behalf of the nation.

Trade With France.—L'Office National du Commerce Exterieur, 3 Rue Feydeau, Paris (France), is an address that should prove useful to Canadian buyers or agents wishing to be placed in touch with the best French manufacturers and producers. Prospective buyers or agents should state very clearly just what they want, and furnish references. Correspondence in English is welcomed.

No Work for the Unskilled.—Dr. A. H. Abbott, director of the Imperial Munitions Board for the Ontario Department of Labor, in a letter to President Falconer of Toronto University, states that there is little need for unskilled help in munition factories at present, and the problem which has to be considered is that of help for the farmers. He points out that in May there may be a greater need for unskilled help in munition factories, because it is probable some of the men employed in the latter at present will go on the farms.

Big Increase in Customs Revenue.—The Customs revenue of Canada for the fiscal year which ends on March 31 will probably exceed that of the last fiscal year by more than forty million dollars. The revenue from customs duties for February the Minister of Customs announced on Feb. 27 amounted to $11,190,000, or $1,062,000 more than those of the corresponding month in 1916. For the eleven months of the fiscal year which have now passed Canada's customs revenue amounted to $130,739,000, as compared with $91,946,000 in the same period of the last fiscal year, or an increase of $38,793,000.

Cunard Line on Pacific—Sir William Mackenzie is authority for the statement that the contract which the C.N.R. made with the Cunard Steamship Co. for the taking over and operating of the former company's Atlantic service contemplates the establishment of a service on the Pacific to be run in conjunction, with the company's land service. Under the contract made it is intended that a trans-Pacific service between Canada and the Orient shall be established. The Cunard Co., has just let contracts for ships to be built in Seattle yards, and these will, when ready, be placed on the Pacific route."

Further Recession in Shipping Risks.—Further recession has taken place in war risk insurance on Atlantic voyages. The rate is now as low as 6½ per cent., compared with 10 per cent. at the beginning of February. Some underwriters, however, are charging 8 per cent. The low rate is on liners and armed belligerent ships bound for the war zone. Mediterranean rates continued at 10 to 12 per cent. and South American rates have held firm at from 5 to 8 per cent. The raider in the Indian Ocean is expected to cause an increase. Some New York underwriters quote war risk

insurance contingent upon shipments within two weeks.

The Turbine Equipment Co., Toronto, have recently closed contracts with the following towns for pumping equipment. Town of Lindsay, 1-De Laval 2 stage pump having a capacity of 1¼ Imperial gals. a day, for domestic requirements, and 1¾ Imperial gals. a day for fire requirements. A vertical high speed gasoline engine will be connected by clutch to one side of the pump, and the electric motor on the other. Contract price was $8000, including installation. From the town of Barrie, Ont., 1- 1½ million Imperial gals. a day, De Laval single stage centrifugal pump, to operate against 87 lbs. pressure and direct connected to 100 h.p. electric motor. From International Nickle Co., Port Colborne, Ont., 1-De Laval 130 h.p. steam turbine driven centrifugal underwriter fire pump.

Engineers Organize for Service.—The engineers and technical men belonging to the various branches of the profession in Ontario have recently organized to lend their technical knowledge in the service of their country. The new movement is known as the Joint Committee of Technical Organizations, Ontario Branch, and is governed by a strong committee composed of representatives from all the known engineering associations of the Province. Representatives have been selected from such institutions as the Canadian Mining Institute (Toronto branch), Canadian Society of Civil Engineers (Toronto branch), Ontario Assoiation of Land Surveyors, Society of Chemical Industry, Canadian section (Ontario members), Engineering Alumni Association of the University of Toronto, Engineers' Club, Toronto, Royal Canadian Institute, Canadian Engineers (Military District No. 2), American Society of Mechanical Engineers (Ontario section), American Institute of Electrical Engineers (Toronto section), Institution of Electrical Engineers (Ontario members), Ontario Association of Architects.

WOODWORKING

Wiarton, Ont.—The Canadian Furniture Mfg. Co. will build an addition to its plant and instal new machinery.

New Westminster, B.C.—The Brunette Sawmills Co., will build an engine and boiler house. The new shingle mill is practically completed.

RAILWAYS—BRIDGES

Fort William, Ont.—M. H. McLeod, general manager of the Western Lines of the C.N.R., stated recently that as soon as the weather is favorable work will be commenced on a $50,000 station in Fort William. The station, which will be of the same model as the depot in Port Arthur, will be erected a short distance north of the present station.

CONTRACTS

Toronto, Ont.—Reid & Brown have been relieved of their contract to supply gulley tops to the city at $5.55. The contract was awarded to The Don Foundry Co., at $6.70 per ton.

CATALOGUES

Circulating Pumps.—A bulletin dealing with a line of circulating pumps for machine tools, has been issued by C. F. Roper & Co., Hopedale, Mass. The principal features of construction and method of operation on the Roper geared pump are described fully, accompanied by illustrations which include dimensioned diagrams for various sizes.

Hydraulic Presses.—An interesting and varied line of hydraulic presses is described and illustrated in a series of leaflets distributed by the Charles F. Elmes Engineering Works, Chicago, Ill. The principal dimensions are given for the various sizes of each type, and also of equipment used in their operation such as hydraulic pumps, valves, etc.

Storage Battery Trucks.—The Buda electric storage battery trucks for railroad shops and manufacturing establishments, made by the Buda Company, Chicago, Ill. Bulletin illustrating and describing several types of the "Buda" industrial trucks. The illustrations feature a variety of purposes for which this truck can be used. Copies may be obtained from the Canadian Agents, the Federal Engineering Co., 92 Sherbourne St., Toronto.

Electric Welding by the "Winfield Way" is the title of an attractive bulletin issued by the Winfield Electric Welding Machine Co., Warren, Ohio. The bulletin describes the Winfield method of welding, also the Winfield electric welder, illustrating many types of machines, both spot and butt welders. An interesting feature of the bulletin is the large number of excellent halftones showing the welder operating in a variety of plants thus demonstrating its wide field of application and utility. Some useful data on spot and butt welding are also included.

Fairbanks Hammers is the title of a catalogue issued by the United Hammer Co., Boston, Mass. The catalogue gives a general description and principal structural features of the Fairbanks hammer, and also illustrates the various types. Tables giving the sizes and details of motor-driven, countershaft-driven and regular pattern hammers are included while reference is made to the wide range of work for which this hammer is adapted. The concluding pages contain a schedule of foundation dimensions and an illustrated list of parts of power hammers.

BOOK REVIEW

Water Powers of Manitoba, Saskatchewan and Alberta, a well-bound and attractively illustrated volume, just issued by the Commission of Conservation, forms a valuable contribution to the authentic literature respecting the natural resources of Western Canada. This report, by Leo G. Denis and J. B. Challies, comprises the results of special surveys by the Commission of Conservation and a compilation of records from other reliable sources. As a compendium of all available data on the subject, it is particularly valuable for reference purposes. While the Prairie Provinces, as a whole, are not lavishly endowed with water powers, the report demonstrates that the utility of their rivers for power development can be vastly enhanced through proper storage of flood waters. At present, in the absence of conservation dams, and of adequate natural regulation, the great volume of flow is lost during high water seasons. Methods of development to ensure the maximum utilization are now being carefully worked out on the Winnipeg, Bow and other large rivers. The more northerly regions possess numerous sites of great potential value for pulp, electro-chemical and other special industries. The report just issued is the second in the series on water powers in Canada to be published by the Commission of Conservation. The third volume, "Water Powers of British Columbia," which is now in press, will complete the Commission's general inventory of this item of the Dominion's natural wealth.

Subsidence Resulting From Mining, published by the Engineering Experiment Station of the University of Illinois.—As a result of underground excavation which is made in the process of mining, the earth's surface frequently subsides to an extent which interferes with the stability of buildings, railroads and other facilities which may exist on the surface. Where subsidence is occurring or in the immediate future is likely to occur, building projects on the surface must take account of these facts. The comparative newness of most of our mines is probably responsible for the fact that the subject only recently has attracted widespread attention. The subject is one which has recently been studied by the Engineering Experiment Station of the University of Illinois in co-operation with the State Geological Survey and the United States Bureau of Mines. The investigators, Professor L. E. Young and Professor H. H. Stoek, have summarized existing facts as presented by the literature on the subject, have conducted an extensive correspondence with mine operators and mine workers throughout the coal mining districts of the United States, and have studied local conditions as they now exist in the mining districts of Western Pennsylvania, West Virginia, Maryland, and Illinois. The results of these investigations are presented in Bulletin No. 91 of the Engineering Experiment Station, a book of 200 pages, well illustrated. Copies may be obtained gratis upon request from W. F. M. Goss, director, Urbana, Ill.

CANADIAN MACHINERY

AND MANUFACTURING NEWS

A weekly newspaper devoted to the machinery and manufacturing interests.

Vol. XVII. TORONTO, MARCH 15, 1917 No. 11

EDITORIAL CONTENTS

THE MACLEAN PUBLISHING COMPANY, LIMITED

Shell Production in a Plant Equipped for Post-War Effort

Staff Article

Much interest attaches to the efforts by means of which our manufacturers hope to maintain, to a considerable degree, the position which the Dominion has attained in the realms of engineering accomplishment. That opportunities await the progressive manufacturer in the near future is generally admitted, and the plant described herewith is one instance where a high degree of preparation has been made for future developments, limited only by the exigencies of present production requirements.

MACHINING MARK VII. 4.5 IN. H.E. SHELL

THE numerous plants engaged in manufacturing munitions throughout the Dominion may be roughly divided into three classes, viz., plants existing previous to the war, plants built specially for shell production with little or no intention of future utilization, and plants built for meantime shell production, but with definite intentions of utilization in certain future activities.

The plant described in this article belongs to the last named class, and is of particular interest at this time as being concrete evidence of the thorough and discriminating manner in which certain of our manufacturers are preparing for peace while engaged in supporting the Arms of Empire. Readers familiar with machine shop equipment and practice will be quick to appreciate the keen perception and sound judgment displayed by the executives of this plant in the selection of its present equipment.

All of the machines necessary for the production of 4.5 in. howitzer shells have been obtained from makers of repute, are of standard design and quality, and are tooled up so as to interfere as little as possible with their future employment on regular machine shop work. The types of machine adopted are such that with very few additional ones the scope of work which can be undertaken in the plant will be greatly widened, and the opportunities for profitable employment in post-war days correspondingly increased.

Building Lay-out

Considerable interest centres in the building, which is of the T design, combining simplicity and convenience of arrangement with efficiency in lighting, heating and shop administration. Fig. 1 is an exterior view of the building, and Fig. 2 a plan. Seven saw-tooth roof lights provide an ample supply of north light, supplemented by liberal sidelights, the latter being of Henry Hope sash with tilting centre sections for ventilation in warm weather; each saw-tooth section is provided with two ventilators of the positive exhaust, swivelling cowl type.

At the present season of the year the heating arrangements are much in evidence. Steam heating is adopted throughout, being supplied by a Kewanee horizontal fire-box type of boiler. High efficiency and great economy of space are obtained by the use of pressed steel radiators, which are mounted on the walls below each window, but well clear of the floor, so as not to favor the accumulation of dust, scrap articles and other refuse.

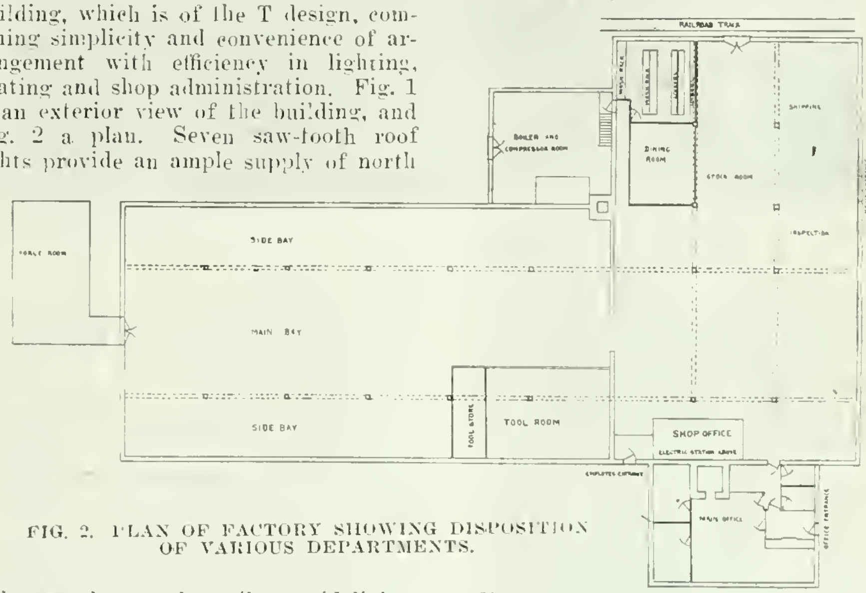

FIG. 2. PLAN OF FACTORY SHOWING DISPOSITION OF VARIOUS DEPARTMENTS.

The building is 181½ ft. long over all, with a width of 64 ft. in the machine shop, and 105 ft. over the receiving, shipping, and stock rooms. A two-storey office building, 42 ft. by 30 ft., extends

FIG. 1 EXTERIOR OF FACTORY SHOWING SAW-TOOTH ROOF, EXTENSIVE SIDELIGHT PROVISION, AND OFFICE BUILDING

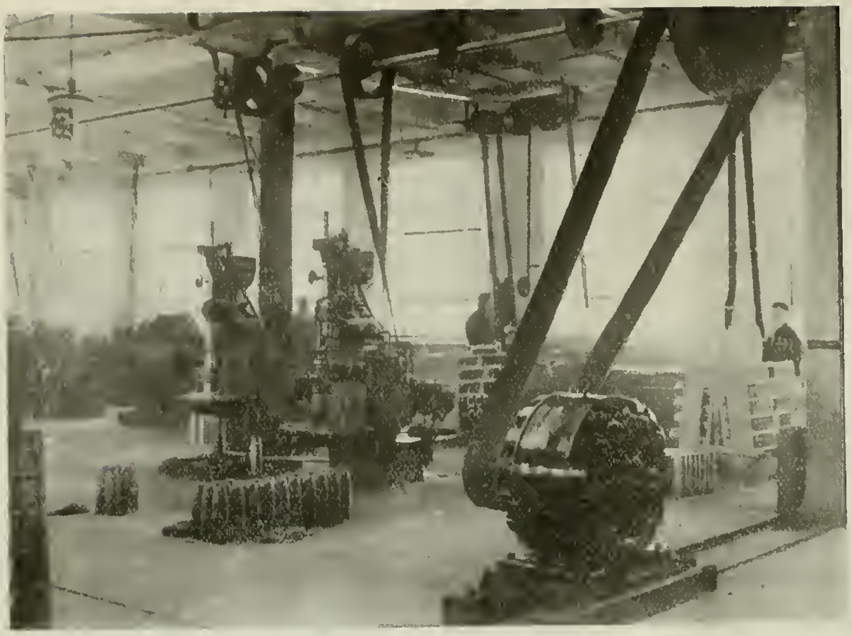

FIG. 3. VIEW OF SIDE BAY SHOWING BALL-BEARING SHAFTING, DRILLS AND AUTOMATIC TURRET LATHES.

across one end of the latter department. The upper floor is occupied by the drafting room, blueprint department, and superintendent's office; while the ground floor provides accommodation for main office, and two private offices. A fireproof vault provides safety deposit facilities for records, etc., on each floor.

Power Supply

Electric power from a supply company is used throughout, while compressed air is supplied from a motor-driven Curtis 9 in. x 9 in. vertical two-cylinder compressor, this service being at present utilized in various ways in the shell work. An idea of the interior arrangements of the machine shop can be obtained from Figs. 3 and 12. Main line shafting extends along either side of the main bay—one 118 ft. x 3 in.; one 80 ft. x 3 in., and 18 ft. x $2\frac{1}{2}$ in., carried in S.K.F. self-aligning ball bearings, and driven by 40, 10, and $7\frac{1}{2}$ horse-power motors respectively.

Incandescent electric lighting is used throughout, nitrogen lamps of suitable power being used wherever suitable, supplemented by high efficiency reflectors. All of the wiring is enclosed in metal conduits and the central control station is next to the office (see plan), the switchboard being located on a mezzanine gallery above the shop office. The employees' entrance is situated here, with time-recording clock and barrier grill, the latter arranged so as to provide suitable space for parties whose business does not require them to enter the shop proper. Team entrance and railroad track are provided for handling goods directly on to floor of shipping room.

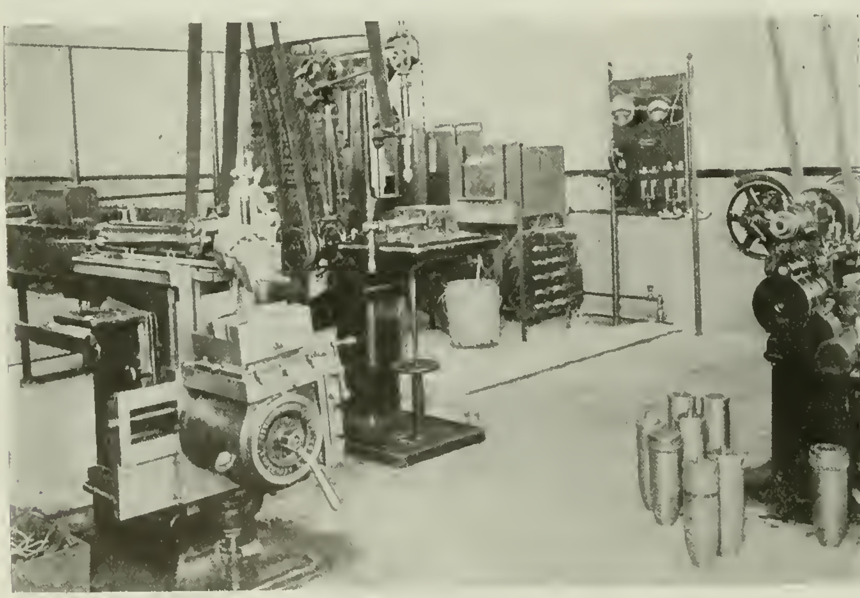

FIG. 4. A CORNER OF THE TOOL ROOM. UNIVERSAL SHAPER AT THE LEFT WITH ELECTRIC FURNACE INSTALLATION IN THE BACKGROUND.

In this part of the building are also provided locker accommodation and dining room, hot water, individual metal lockers, and comfortable restaurant equipment.

Tool Room

Tool room equipment for handling shell work must be capable of dealing with a higher proportion of cutters and other heat treated parts than usually obtains in the ordinary run of jig and fixture work, lathes, drills, shapers, and grinders being perhaps the essential tools required. A corner of the tool room is shown in Fig. 4, prominent items of equipment being a Potter & Johnston universal tool-room shaper, a single-spindle Henry & Wright sensitive drill, and two Hoskins electric furnaces. Remaining items in the tool-room include a hack saw machine, a McDougall 10-in. vertical drill, one McDougall 16-in., one Hamilton 14-in., and one American 14-in., tool-room lathes, one LeBlond tool-room grinder, one drill grinder, and several individual benches, with Parker universal vises. The tool crib is liberally provided with steel shelving of suitable design.

Shell Manufacture

No effort has been made to originate special machining methods, the underlying principle being to obtain a maximum output of good work, while maintaining the machines in a high state of general efficiency and ultimate adaptability to special or general machine work. With this object in view, such work as equipping LeBlond engine lathes for rough turning was done with practically no material alteration to the machine itself, all special tool-holders, profile bars, counterweights, etc., being attached by clamps, so that only one $\frac{5}{8}$-in. tapped hole has had to be drilled to attach the fixtures.

The initial operation of roughing out the bottom is done in a Barnes all-geared drilling machine, the metal being removed to a point where soundness of material is assured. With this as a starting point, the base is cut off and the mouth trimmed in cutting-off machines of the Williams type, and the base is then centred on a small special machine constructed of an old 16-in. lathe bed. The chuck holding the centre drill is mounted on a spindle with screw feed, carried on a hinged member, which swings up and back, allowing the forging to be conveniently removed from the driving arbor on which it is supported.

Illustration, Fig. 5, shows the forging being rough turned on a 21-in. heavy duty LeBlond lathe. These and several other machines have been fitted with air chucks by the Manufacturers' Equipment Co., the rapid handling, due to this device, having enabled considerably increased output to be obtained. The shell is roughed to the dimensions in sketch, Fig. 6, and is then bored out on similar machines fitted with the maker's standard type of turret carriage.

Three tools accomplish this work, a single point boring bar, a bottom roughing cutter, and a finishing reamer for

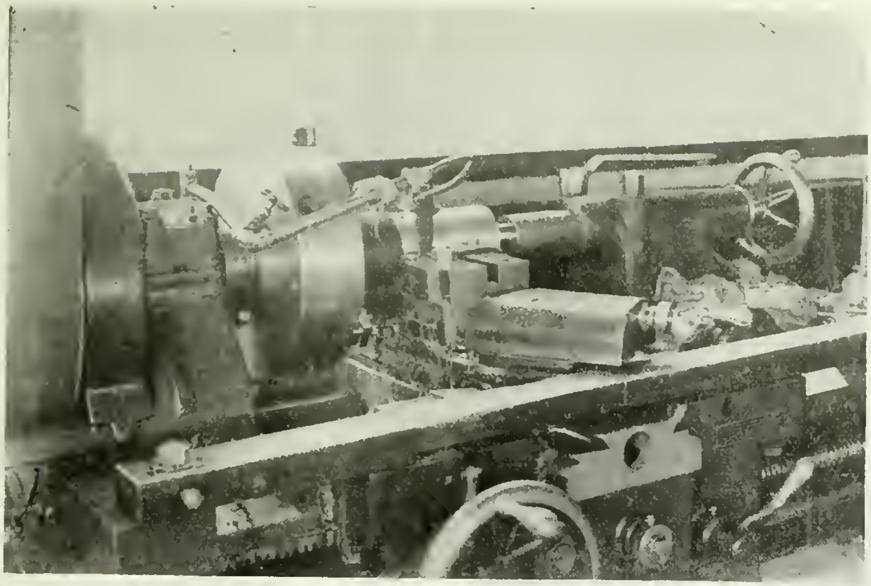

FIG. 5. ROUGH TURNING FORGINGS ON A "LEBLOND" HEAVY DUTY LATHE WITH DETACHABLE PROFILING BAR.

bore and bottom. During the latter part of this operation a bevel is turned on the outside of the mouth in accordance with nosing requirements. Fig. 7 shows the type of spade tool used, the cutting edges being of unequal length to insure a clean surface in the centre.

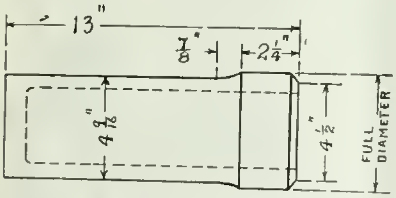

FIG. 6. DIMENSIONS OF FORGING READY FOR NOSING-IN HAMMER.

Forging the Nose

Excellent results are obtained through the use of a Beaudry power hammer, which is provided with suitable forging dies and a chuck for holding the forging by the base (see Fig. 8). This chuck is arranged to feed forward while the work revolves, the forged nose being accurately centred and possessing ample metal for subsequent finishing, both inside and outside. The Frankfort furnace installation is complete with oil pump, blower, etc., and has capacity for heating seven shells simultaneously. A

FIG. 7. SPADE TOOL FOR FINISHING INSIDE OF BASE.

10 horse-power Lincoln motor operates this department, which is housed in a separate structure at the end of the machine shop. Apart from the fact that satisfactory results are obtainable by any of the various methods of nosing-in, the adoption of the power hammer method would appear preferable in this case because of its ultimate sphere of usefulness in ordinary shop work.

In this department are also installed two tanks with lye solution and hot water for washing purposes, provision for heating in summer time being made through a 22 in. x 4 ft. 6 in. vertical boiler.

A battery of Potter & Johnson 6 A automatic machines equipped with Lincoln individual motor drive takes care of the finishing operations on the nose and the recessing of the base. In the former operation, the shell is held in air chucks of the type previously mentioned, which grip the body of the shell over a length sufficient to insure accurate location of the nose, which is now bored to size, recessed, reamed and beveled.

Body Finishing

The design of dies used in forging, combined with the proper allowance of metal result in a minimum of stock to be removed in the final turning of the entire outside. A 16 in. Stevens lathe with parallel and radial tool boxes performs this work in good shape.

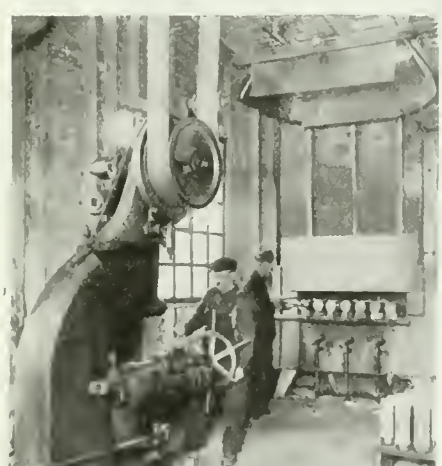

FIG. 8. BEAUDRY POWER HAMMER AND FRANKFORT OIL-FIRED FURNACE HEATING AND FORGING THE SHELL NOSES.

The carriage is provided with two separate tool boxes as shown in sketch plan Fig. 9. Each is adjustable individually while the perpendicularity of the radial link, and its points of swinging are adjusted by two sets of lock nuts at the back of the carriage. Tubular cutting tools enable a maximum cut to be taken with the required degree of finish on the surface while the peculiar shape of the tool allows the entire circular cutting edge to be utilized, giving five or six times the life of an ordinary tool between grindings.

After tapping the nose in vertical drilling machines with collapsible taps, the interior profile is finished or blended with the parallel bore, a LeBlond turret lathe with solid formed cutter bar making an excellent job. A number of the P. & J. automatics mentioned are tooled up for base recessing grooving and waving. The layout of the tools is shown in Figs. 10 and 11, which shows the completed shell ready for removal. The various stations of the turret are numbered in rotation, No. 4 having a spring-backed supporting bearing which

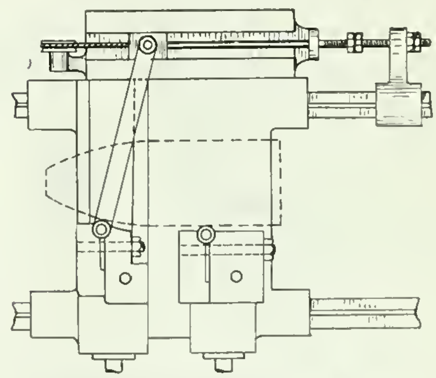

FIG. 9. PLAN OF LATHE CARRIAGE WITH TUBULAR TOOLS AND RADIAL LINK FOR GENERATING PROFILE CURVE.

takes the side thrust due to the grooving and waving tools.

Minor Operation

Following this in rapid rotation, the under cutting is done in a Roelofson band turning machine with diagonally sliding cutters, followed by washing, air blasting with steel shot in a Curtis outfit and complete inspection prior to notching the nose and riveting in the base plates. A High Speed Hammer Co's. machine is used for the latter operation, the riveting ram being revolved by power while working insuring even wear on the point with uniform results from each blow and consequent ease of control.

The notching referred to is the three small grooves now required on the point of the nose, and a discarded thread milling machine provided ready means of doing this. A special cutter spindle was arranged transversely to suit the position of the grooves and three dividing holes provided on the back plate which holds the shell inside the hollow headstock spindle. The shell nose contacts positively with a hardened plate on the cutter support insuring uniform results.

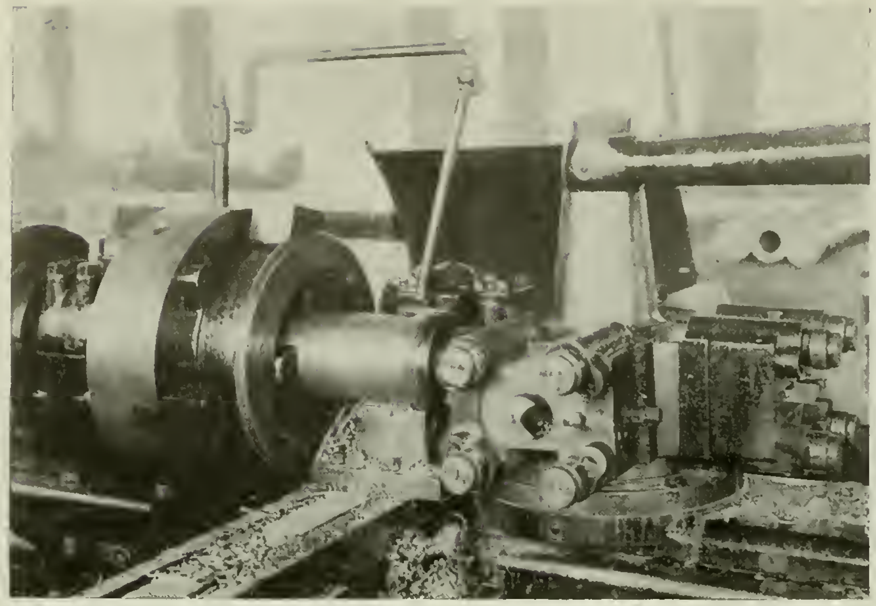

FIG. 10. VIEW OF "POTTER & JOHNSTON" AUTOMATIC WHICH RECESSES BASE AND MACHINES DRIVING BAND GROOVE COMPLETE AT ONE SETTING.

Banding and Varnishing

After facing the bases, the bands are pressed on with a Goldie-McCulloch press operated by a Smart-Turner three-throw pump operating at 1500 lb. per sq. in. The turning of the band to the correct diameter and profile is done in a Roelofson band turning machine. A quick acting chuck, with two cutting tools and ample belt power enables one machine to keep pace with the balance of the equipment, graduated feed dials and rigidity of tool supports giving desired accuracy in results. This equipment is shown in Fig. 12.

A further washing and inspection is now given before varnishing and baking, these latter being done in a dust-proof room. A Paasche air brush equipment has been installed for varnishing the interior surface. Air at 80 lbs. pressure is passed through a small electric heater on the wall, Fig. 13, and atomises a gravity supply of varnish, the mixture depositing a uniform film of varnish, free from bubbles, and with a small consumption of time and material. An electric oven with two trucks performs, the baking, one truck filling while the other is heating.

Painting is performed by hand while the shell is revolved by power. Boxing and shipping which follow after, being performed under the supervision of government officials.

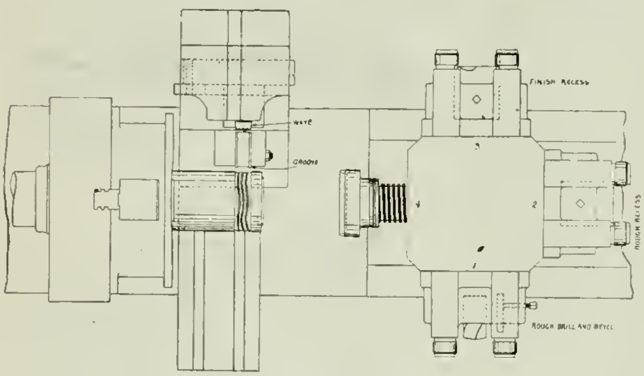

FIG. 11. LAYOUT OF TOOLS IN FIG. 10. SHELL IS SHOWN READY FOR REMOVAL.

FIG. 12. BANDING DEPARTMENT, SHOWING HYDRAULIC PRESS WITH "ROELOFSON" BAND TURNING MACHINE AT RIGHT.

LOCOMOTIVES FOR CANADIAN GOVERNMENT RAILWAYS

A CONTRACT for twenty more heavy Mikado freight locomotives for the Canadian Government Railways has been awarded by the Minister of Railways to the Canadian Locomotive Works, Kingston. Already the work is in such shape that the first engine is on its way to the Intercolonial Railway to help cope with the present heavy movement of freight to the seaboard. Deliveries have been completed by the Canadian Locomotive Works under an earlier order for thirty locomotives. These engines cost about $39,000 apiece, or almost 100 per cent. more than pre-war prices. In addition, the department purchased 10 Santa Fe Moguls at $36,468 in bond Montreal, and 28 second-hand locomotives from Transcontinental contractors. A total of 88 engines have thus been bought or ordered for the Government railways during the present fiscal year.

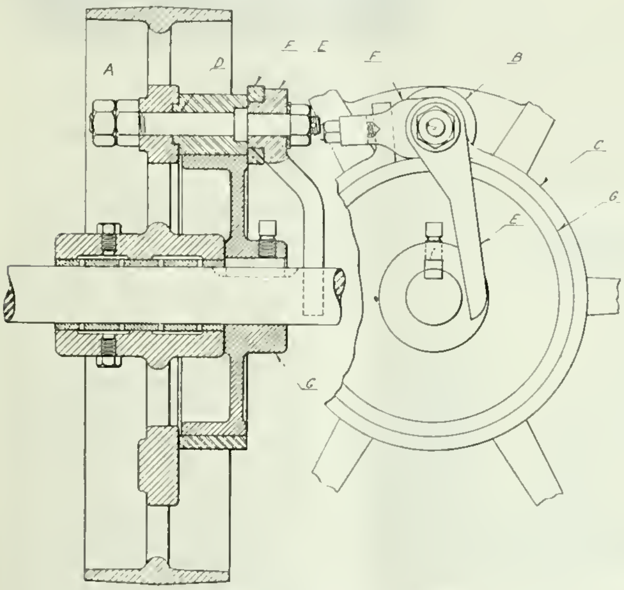
PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

FRICTION CLUTCH FOR COUNTERSHAFT

by J. H. R.

THE matter of suitable drive for machine tools is an important factor not only in the production of munitions but in that of other manufactured articles as well. While recent applications of machine drives do not bear directly upon the munition problem, many of these have been developed to overcome difficulties arising out of this industry. The clutch here shown was designed and constructed by the John McDougall Caledonian Iron Works, Montreal, for the purpose of increasing the efficiency of shell turning lathes. Contrary to the general practice of an expanding spring clutch ring, the method adopted in this device has been to use a spring ring that closes on the outer diameter of the driving hub G. One end of the spring clutch ring C is secured firmly to the boss B of the loose pulley. The operating lever arm E, when forced outward by the slip sleeve (not shown), draws the two ends of the clutch ring C together, gripping the driving hub G. With the interior ring, there is generally a tendency for the clutch to creep, this being caused by the centrifugal action of the spring ring. With the type here shown, the motion, when clutch is out of action assists in preventing contact between the two friction surfaces.



FRICTION CLUTCH FOR COUNTERSHAFT.

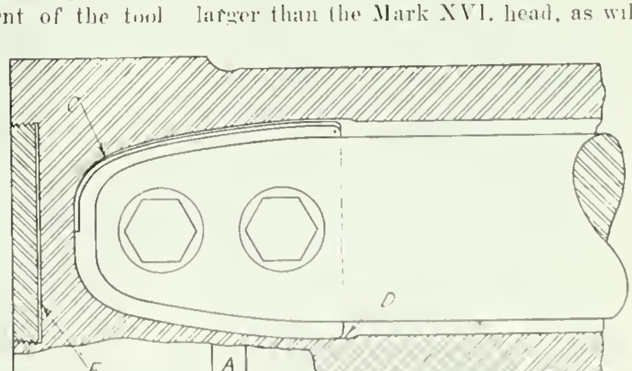
SHELL MAKING TROUBLES

by R. O.

WHERE the percentage of defective shells in any munitions machinery plant is abnormally large, the cause may be attributable to the dullness of the cutting tools employed in the several processes, a circumstance largely due to lack of appreciation on the part of operators of the degree of efficiency to which maintenance is essential to ensure both quality and quantity production.

Dull tools are also the source of more or less trouble and expense. A common result of dull cutting tools is shown at A in the sketch, where the tool is set at an oblique angle (in a forward direction), to the parallel travel of the tool. When roughing the outside of shell forgings, the variation in depth of cut is often considerable, resulting in variable strains being placed upon the tool itself, and also on the containing parts. This feature, alone or in combination with others, tends to force the cutting end of the tool in the direction of the arrow; if a keen edge be not maintained on the tool, or extreme hardness in the shell be encountered, resulting in rapid deterioration of the tool cutting qualities, a tendency to swing becomes at once obvious. If set at the angle shown, any shifting of the tool from above causes will result in a gradual reduction in diameter, or probably a groove as indicated. Whenever possible, tools should be set at right angles to the direction of the cut, so that any movement of the tool in its support, caused by excessive pressure, will reduce the depth of cut, forcing the tool to cut a larger diameter and thus avoid spoiling the work.

Similar conditions may result on the inside bore operation, but, owing to the different method of tooling, the effect is somewhat varied. When in a munitions plant some time ago, I was shown a 60 pdr. shell that had been cut lengthways through the centre to demonstrate a fault that had originated by reason of too much stock removed from the inner base, in addition, the dullness of one portion of cutter blade was contributory. The section of the cut shell showed an enlarged chamber at the base, slightly greater in length than the forming blade and having a diameter about 1-32 inch larger than the main bore of the shell, as shown at D. Investigation proved that several shells had been rejected for this reason; and it was also discovered that the cutters used had a dull portion at the point C. Aided by the length of the boring bar and the poor cutting of the section C, the side thrust had the effect of enlarging the chamber as indicated.



FEATURING SHELL MAKING TROUBLES.

I was shown a shell recently that had been cut to demonstrate the cause of its rejection, to wit, a defective base plate. This plate was of the threaded type and had been coated with cement and screwed in, the fit being apparently very snug. The cut shell showed that contact had not been made with the two surfaces as indicated at E. A reasonable cause of this was the inability of the trapped air to escape, the compression being so great as to prevent the direct contact of iron and iron. After this discovery, base plates were not permitted to be screwed in so tightly, the riveting process taking place after the plates had bottomed.

RAPID CAPSTAN LATHE WORK

Herbert's Monthly.

MANY firms who are now manufacturing the 6-in. high explosive shell, Mark IV., were previously working on the Mark XVI. shell, and the capstan lathes which had been installed for producing the heads of the latter shell were naturally changed over to the Mark IV. head when the transition took place. The Mark IV. head is, however, much larger than the Mark XVI. head, as will be seen from Fig. 1, and the additional duty on the capstan lathes was very considerable. The way in which capstan lathes are handling this work is a remarkable revelation of the reserve in strength and power which these comparatively small machines possess, while the rate of output which is being obtained on the Mark IV. head is all that can be desired.

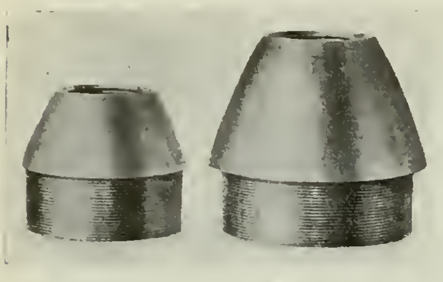


FIG. 1—MARK XVI. AND MARK IV. HIGH EXPLOSIVE SHELL HEADS.

In one works, the material for the head is in the form of blanks cut from mild steel bar; this form of material being found much more satisfactory to machine than forgings or pressings, which are usually scaly and not uniform in size. The lathe operations on blanks are three in number, two of which, namely, the first and third, are performed on No. 4 Capstan Lathes. The first operation is shown in Fig. 2, where the blanks are held by special jaws in a 12-in. Coventry chuck, the blanks being set back against the steady-bush in the chuck. The tools are numbered in the lay-out according to the sequence of operations, which is as follows:—

1.—A standard flat centring tool, which provides a true start for the drill.

2.—A Herbert patent straight flute drill, with inserted spiral cutter. The size used is $1\frac{3}{4}$-in.

3.—A standard knee-turning tool holder for rough turning the thread diameter, provided with a pilot bar which fits in the drilled hole. Although it would be possible to use a plain pilot bar fitting in the steady bush, the arrangement shown is the better one, inasmuch as it avoids undue wear on the steady bush.

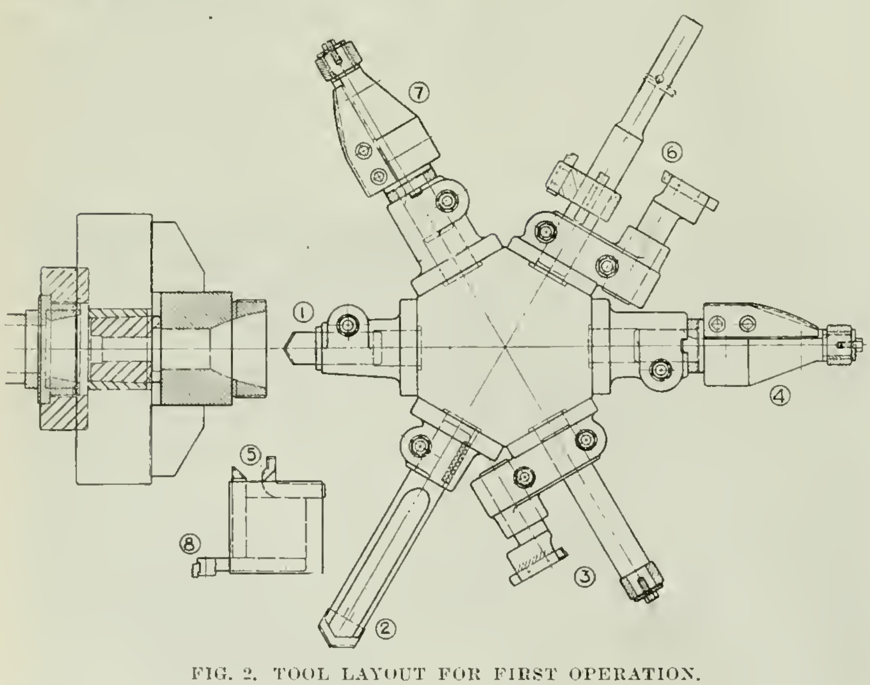

FIG. 2. TOOL LAYOUT FOR FIRST OPERATION.

4.—A single blade form counterboring tool, provided with a revolving pilot bush fitting in the drilled hole. Owing to the heavy cut, a driving collar is provided, which engages with a slot cut across the end of the boring bar holder.

5.—A facing and recessing tool for the shoulder and a chamfering tool for the end carried in the square turret. These operate simultaneously with 4.

6.—A standard knee-turning tool with cutter for finishing the thread diameter. It also carries a boring bar for finishing the 1.82-in. diameter, and for forming the radius at the mouth of the counterbore.

7.—A finish counterbore, identical with 4, except that the bush fits the finished bore.

8.—An inverted chaser holder for cutting the thread.

In some works, we have seen this op-

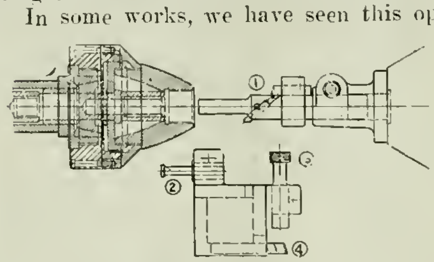

FIG. 3. TOOL LAYOUT FOR THIRD OPERATION.

eration performed in 15 minutes, and we are informed by the management that some of the girl operators have brought the time down as low as 12 minutes.

The second operation, which consists of turning the external profile, is done on an engine lathe fitted with profile attachment. The operation is split up into two parts, which are done on separate machines, and it is interesting to note that the finishing cut is done with a Stellite cutter, the work running at a surface speed of 250-ft. per minute.

The lay-out for the third operation on a No. 4 Capstan Lathe is shown in Fig.

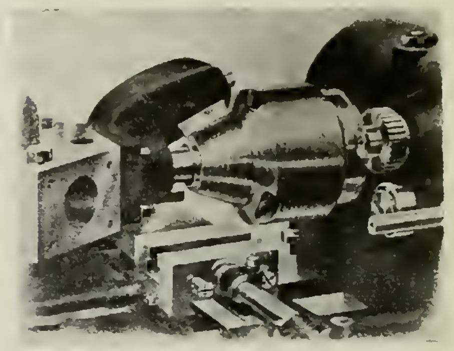

FIG. 4—HERBERT NO. 4 CAPSTAN LATHE ON THIRD OPERATION.

3, where the work is held by the external thread in a Herbert special drawback chuck. The tools are as follows:—

1.—A boring bar for opening out the thread diameter. It also carries a collar and cutter for rough forming the fuse seat.

2.—A circular cutter carried in the square turret, for forming the recess at the back of the thread.

3.—A circular internal chaser, by which the thread is cut to gauge without the use of sizing taps. The patent chasing saddle makes this operation an exceedingly rapid one.

4.—A finish form tool for the fuse seat, which is used in the square turret so as to ensure it being true and concentric with the chasing.

A time for this operation, taken in a number of plants with the foregoing equipment installed, was three minutes.

In some factories the Mark IV. head is being handled at two operations, the second and third being combined so that the external profile is formed on the No. 4 Capstan Lathe. The special tool for doing this part of the work is shown in Fig. 4.

SWEDISH TRADING LICENSES

WEEKS of valuable time continue to be wasted by representatives of American industrial firms because they or the concerns responsible for them have neglected to inform themselves about conditions governing the transit of wares across Sweden. There are few and negligible exceptions to the rule that everything destined for Russia requires a license before it can cross Sweden, and this rule applies as well to samples.

Licenses can be secured by the intervention of the British Legation at Stockholm, but the time required varies from four or five days to as much as three weeks. Canadian business men going to Russia with samples should forward to the Legation there a complete list of the articles, together with data establishing their identify as British citizens and setting forth the approximate date of their arrival. If this is done, the British Minister will have the transit licenses ready when the applicants arrive.

STEEL INDUSTRY DEVELOPMENTS

The War-Created Stimulus given the Steel Industry is Reflected alike in the Nature and Application of New and Improved Equipment being Installed and Developed.

UNIFLOW STEAM ENGINES FOR STEEL MILLS*

By W. Trinks.**

THE trend of power supply in iron and steel plants has been to electrify every machine, up to and including the main rolls, and to concentrate the power generating apparatus in a central power house containing steam turbines in regions of cheap fuel, and gas engines with an auxiliary steam turbine for overloads, in regions of expensive fuel. Into this evolution stepped the uniflow engine, which promises or threatens (depending upon the viewpoint), to change the march of events. The iron and steel plant electrical engineer is particularly interested in this problem because a change would deeply affect his work. For him the two following possibilities are of importance:

The uniflow engine may find a place in the works power plant, or else it may drive rolling mills directly, doing away with the double conversion of mechanical into electrical power in the central station and back again into mechanical at the mill. In Germany the uniflow engine has, in many places, been used for direct rolling-mill drive in preference to electrical drives. The question to be studied is, then, what has been accomplished on this continent in the development of this type of engine, and what is the outlook for the future?

Historical Features

The history of the uniflow engine begins in 1907. In that year Professor J. Stumpf, of Charlottenburg, Germany, made his designs and applied for patents. The characteristic part of the Stumpf engine, as is perhaps already well known, is the cylinder with steam admission at the ends, discharge in the center, and steam jacketed heads, as shown in Fig. 1. The idea of steam admission at the ends in combination with central discharge is old and was patented by Todd in England in 1885, but the fact that the idea remained wholly unused until Stumpf proved that it was useful when coupled with jacketed heads and a partly jacketed barrel, credits Stumpf as the inventor of the uniflow engine from the viewpoint of the critical historian.

In 1907 Professor Stumpf clearly recognized the thermal advantages to be gained from the unidirectional flow of steam through the cylinder. In the summer of that year he fully explained his view upon the subject to the author of this paper at Charlottenburg, Germany. At that time the drawings of the experimental uniflow engines were well in hand. From 1907 to 1911 the evolution of that type of engine was limited practically to Austria and Germany. In 1911, Professor Stumpf published his well-known book on the uniflow engine, and bitter literary controversy on the merits or demerits of the Stumpf engine followed. In the same year American engineers began to take notice of the Stumpf engine and, one by one, the C. & G. Cooper Co.; the Nordberg Mfg. Co.; the Mesta Machine Co.; the Skinner Engine Co.; and the Ames Iron Works took up the building of this type. A great deal had to be learned by these firms, and some of the experience was paid for quite dearly. At the present date, the period of experimenting is practically over, and the time is ripe for a review of the situation.

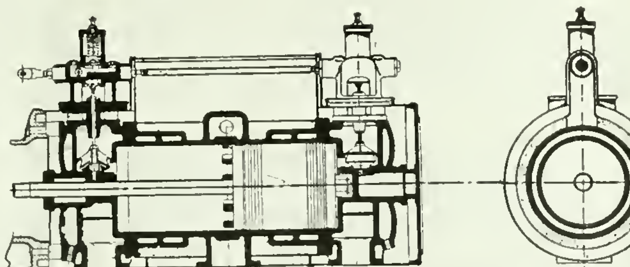

FIG. 1. LONGITUDINAL AND CROSS SECTIONS THROUGH STUMPF UNIFLOW ENGINE CYLINDER.

The principal claims for the uniflow engine are economy, simplicity, reliability and freedom from attendance. Let us consider these features in the order mentioned and then judge whether we can profitably use the Stumpf engine in our work.

In the steel works power plant this engine will have to compete with the gas engine and with the steam turbine. The gas engine was 7,500 to 9,000 British thermal units per indicated horse-power hour, whereas the uniflow engine, running condensing, uses from 11,000 to 13,500 British thermal units in the steam, and more in the fuel gas, depending upon the boiler efficiency. There is, in consequence, little hope of replacing the gas engine by the uniflow engine.

Steam Turbine Comparison

When we come to a comparison between the engine and the turbine, variation of steam pressure and of back presure makes it advisable to leave the British thermal unit basis and to introduce Rankine cycle efficiency, which means the ratio of the work actually produced from unit weight of steam to the work which could be produced by the same weight of steam passing through the Rankine cycle. From a great number of published tests made on the very best turbines, the author has formed the following averages for condensing operation:

Size of turbine, kw......	500	1,000	2,000	5,000	10,000
Rankine cycle efficie'y	0.62	0.66	0.71	0.77	0.82

(Referred to brake h.p.)

For non-condensing operation the values are much lower.

For the Stumpf engine, data furnished by the Stumpf Uniflow Engine Co., tests made by the author, and data from Ames Iron Works and from the Cooper Co., indicate the following efficiencies:

Size of engine, kilowatts.........	300	600
From 3 lbs. per sq. in., back pressure above atmosphere down to about 23 in. vacuum.		
Efficiency:		
Saturated	71	74
100 degrees superheat	75	77
200 degrees superheat	78	79
For high vacuum (about 27½ in.):		
Saturated	58	62
100 degrees superheat	62	65
200 degrees superheat	66	68

The values may vary somewhat to one side or the other, but the general tendency is apparent. For non-condensing operation, at 100 degrees superheat, with moderate vacuum, and for sizes up to 1,000 kilowatts, the uniflow engine is more economical than the turbine. It will, therefore, find a place in comparatively small power plants, and in locations where 28 inches of vacuum or better is not obtainable. It will also be preferred for generating direct current, because turbines for the generation of direct current, when direct connected, are too slow for best economy. If they are to operate at economical speed, gears must be introduced.

Limited Field in Steel Works

Evidently, the uniflow engine will have a very limited field in the steel works power plant. Turning to the

*From a paper presented at the 10th annual meeting of the Association of Iron and Steel Electrical Engineers.

**Professor of Mechanical Engineering, Carnegie Institute of Technology, Pittsburgh, Pa.

second application which interests us, namely, the driving of rolling mills, we find a changed condition. Let us for the sake of clearing up doubts, compare the uniflow engine with electric drive, and with older type of duoflow engine. In comparison with electric drive, the steam engine does away with the electric generator, the switchboard, the transmission line and the motor, but it takes undesirable piping into the mill. The elimination of the electrical part means that we must compare the Rankine cycle efficiency of the engine to the Rankine cycle efficiency of the turbine, including generator, transmission line and motor. Allowing the high efficiencies of 92 per cent. for the generator, 98 per cent. for transmission line and 92 per cent. for the motor, we must multiply the turbine efficiencies by 0.83 for comparison with the direct-connected engine.

This procedure furnishes the following:

Size of turbine, kw.	500	1,000	2,000	5,000	10,000
Rankine cycle efficiency:					
Referred to motor shaft	50	54	59	64	68
Referred to mill shaft..	47	50	55	60	64

The lower row of figures was obtained by multiplying the upper row by 0.965, this figure taking care of the efficiency of two speed reductions from the motor to the mill. A study of the resulting values shows that the uniflow engine is ahead of the electric drive, unless the steel plant is so large that turbo units of over 8,000 kilowatts capacity can be installed.

The economy of the uniflow engine compared to that of the steam-turbine-electric drive, taken by itself, is not enough better to explain why the uniflow engine should fare differently from the compound engine. The Rankine cycle efficiency of a good compound engine is practically the same as that of the uniflow engine, but there is one difference. To obtain that high efficiency, the compound engine must have a small high pressure cylinder; but the small size of the latter means a small overload capacity, and quick departure from the best efficiency for comparatively small changes of load.

Compound Engine Comparison

Fig. 2 shows the water-rate-against-load curve for a well known compound engine. Comparison of this curve with the typical water rate curve of a uniflow engine, Fig. 3, shows the difference to be very marked. Mill loads are notoriously variable, because small variations in draft, temperature of steel, velocity of rolling, etc., cause disproportionately great changes in resistance. It is not possible to exactly foretell what the load will be, and it is therefore of the utmost importance to secure a drive which permits over or underloading without serious change of economy. The uniflow engine, and the electric motor hitched to a large central station, both fill this requirement.

The old type simple duoflow engine, the old reliable standby of the rolling mill for over 50 years, cannot be considered here. It is so wasteful, that its low price is more than offset by increased cost of boiler house equipment, not to mention the continuous cost of fuel and water. It retained its place in the mill a long time, due to its simplicity, but was replaced here and there by the compound engine on account of its wastefulness. The uniflow engine combines the simplicity and overload capacity of the simple engine with the economy of the compound engine; it has the added advantages that its overload capacity is even greater than that of the simple engine and its economy is sustained over a greater range of load. Finally, it has very few moving parts and takes up much less floor space than the compound engine.

Variation in back pressure naturally affects the operation of the uniflow engine. However, the vacuum may, with 4 per cent. clearance, vary from 19 to 27 inches of mercury without unduly high compression, or pounding, due to lack of compression. If the vacuum fails altogether, clearance is automatically added, to keep the compression down.

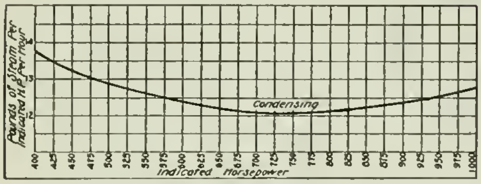

FIG. 2 WATER RATE LOAD CURVE OF ORDINARY COMPOUND ENGINE.

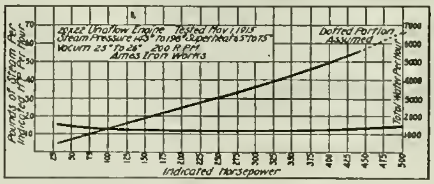

FIG. 3. WATER RATE LOAD CURVE OF UNIFLOW ENGINE.

Uniflow Engine Development

A great deal has been written on the reasons for the economy of the uniflow engine; nevertheless the author will try to present the underlying facts again in as concise form as possible. The secret of the economy of the uniflow engine lies principally in reduction of internal cylinder condensation. In the duoflow single expansion engine, cylinder condensation is so great, that a very great free expansion loss must be allowed for best economy (or rather for minimum wastefulness). In the compound and triple expansion engine, cylinder condensation is reduced so that the free expansion loss can also be reduced, but mechanical losses due to the passing of the steam through so many valves becomes great. In the duoflow engine, cylinder head, cylinder barrel and piston head are alternately heated and cooled by live steam and exhaust steam sweeping over them and wiping heat "on and off".

In the uniflow engine, only the piston head has heat wiped off during the extremely short period of exhaust, the steam near the place of entrance of live steam being at rest like the fixed end of an expanding coiled spring during exhaust, and like that of a compression spring during compression. Besides, the cylinder head and part of the barrel are steam jacketed, and steam jacketed surfaces are cooled very little by stagnant steam. It may be remarked again that the mere provision of a central exhaust does not bring about a successful uniflow engine; the steam jacketing of the heads and of part of the barrel must go with it, to produce the thermodynamic superiority over the duoflow engine.

In the duoflow engine, long compression means increased steam consumption, principally, because the steam temperature exceeds the cylinder (or piston) wall temperature a longer time than it would with shorter compression. In the Stumpf uniflow engine the steam which is being compressed is in contact with progressively hotter surfaces, with the exception of that of the piston, and the steam temperature never rises very much above the wall temperature.

The second reason for the economy of the uniflow engine lies in the enforced or compulsory tightness Steam cannot leak from the live steam space to the exhaust. If the inlet valves are leaky to any exent, the compression rises so quickly that the inlet valves clatter and give notice to the engineer that something is wrong.

In comparing test data with calculation results, I have obtained very good results by using Heck's formula for the internal condensation or missing quantity, but I substitute instead of his constant C the value

$$C - \sqrt{\frac{^\circ\text{F. superheat}}{4{,}500}} \text{ for duoflow}$$

engines, and $0.45\ C - \sqrt{\frac{^\circ\text{F. superheat}}{10{,}000}}$

for uniflow engines.

Uniflow Engine Economy

The development of the uniflow engine in the United States has been slow, probably because it did not fit into the general trend of changing from reciprocating to rotating machinery, and because it is of foreign origin. It began in a small way in 1912. The C & G. Cooper Co., Mount Vernon, O.; the Nordberg Co., Milwaukee, Wis., and the Mesta Machine Co., Pittsburgh, began almost simultaneously to build experimental engines . All three firms moved cautiously and equipped their engines with Corliss gear. All three found out that the Corliss releasing gear, in its usual form, is not ideal for the uniflow engine, because the cut-off is so short, because modern plants carry high pressure with superheat, and because the pressure drops so fast after cut-off, that the valve becomes unbalanced too quickly for the ordinary design and size of vacuum pot. In consequence, the Mesta Co., and the Nordberg Co. switched over to poppet valve gears, while the Cooper Co. adapted its Corliss gear and vacuum pot to the new conditions.

The smaller sizes of uniflow engines have been developed by the Ames Iron Works, Oswego, N.Y., and by the Skinner Engine Co., Erie, Pa. The Ames Iron Works, from the very beginning, adopted poppet valve steam distribution, with shaft governor drive. This design is very well adapted for small engines up to 400 or 500 horsepower, and is very successful. For larger sizes and high steam temperature it is not so well adapted, because the difference in expansion between the valve rod and the cylinder becomes too great and disturbs steam distribution. For poppet valve engines above 500 horsepower the lay shaft drive is preferable.

In the sizes built by the Ames Iron Works, a self supporting piston, guided at the crank end only, is said to be satisfactory. In larger sizes this same design leads to a great deal of trouble. On account of difference in expansion, the piston must fit very loosely in the cylinder. The guiding of the piston by the crosshead is very imperfect. The piston, therefore, wobbles around in the cylinder, riding now on one spot, then on another, never wearing itself in, but rapidly wearing itself out. In large engines of German design, a tail rod guide has been provided, not so much for the purpose of carrying the piston, but mainly for the purpose of guiding it, so that it will always touch the cylinder in a large surface. American engineers have gone one step further and have made the piston rod strong enough to carry the piston.

Early Troubles

The early part of the practical development was thorny. Cracked cylinders, heads and bed plates caused trouble; valve gear troubles and regulation troubles had to be overcome, pistons and cylinders wore too rapidly; but the problems have all been solved and the future promises to be free from any obstacles whatsoever. Whatever troubles were experienced, naturally appeared more forcefully in the larger sizes, with the result that the smaller sizes, developed by the Ames Iron Works and the Skinner Engine Co., have made more progress in numbers than the larger sizes. It can safely be said that the uniflow engine to-day is as reliable as the simplest engine of the duoflow type. Additional steam consumption charts may be appreciated. To the scientific engineer they do not mean as much as Rankine cycle efficiencies, but habit has led many of us to think in pounds of steam per horsepower-hour. Consequently, Fig. 3 is given showing steam consumption of various types and sizes of uniflow engines.

BRITISH SHELL CONTRACTS IN UNITED STATES

REGARDING the reports that munition makers in the United States had been notified by the British Government that all contracts for the manufacture of shrapnel and other shells must be completed by March 31, and that on that date all contracts in existence for these war materials will lapse, an interest who has been in touch with the various orders placed in that country discusses the matter as follows:—"The foregoing statement is untrue. It applies only to such contracts as were originally scheduled for completion by the date mentioned. In this case, contracts will lapse, but this is nothing particularly new, because there have been several cancellations of arrearages on deliveries up to the present time. Contracts that were placed originally with a longer period of leeway for deliveries than March 31 next will be permitted to remain as per agreement and be carried out in accordance with stipulations."

It will be recalled that earlier in the current year it was announced that a number of contracts had been cancelled, but it developed that in each instance a cancellation clause was contained in the agreement. Much of this also was for materials in arrears; that is to say, companies which had agreed to deliver a certain number of shells by a given date, and having delivered only a part, were notified to cancel the balance that should have been shipped up to the time specified.

SEMI-PRECISION GRINDING

RAILROAD frogs, switches, crossovers, safes, large pinions and gears, dredge buckets and so forth, composed of alloy steels, usually manganese steel, are machined on boring mills, planers, shapers and sometimes on lathes by means of grinding wheels. A considerable amount of leeway in the finished dimensions is permissible, in some cases as much as one-quarter inch. The name "semi-precision" is applied to this class of operations.

When a piece is ground in a boring mill, it is firmly clamped to a horizontal revolving table and the grinding wheel is brought in contact, either on the outside or the inside of the casting. A motor is placed on top of the vertical crossrail in such manner that the armature of the motor is in a vertical position. The armature of the motor is extended so that at the bottom end of the vertical crossrail it becomes the spindle for the grinding wheel.

Operations of this nature are performed on a planer by attaching a portable electric grinding machine to the crossrail. Special types of planers are in use, notably the open-side type planer used for surface-frogs and switches. Here, the grinding wheel spindle is belt driven from an individual motor, located above and at the rear of the head which carries the spindle, because it is not convenient to have the wheel spindle directly connected to the armature of the motor.

When a shaper is used for semi-precision grinding, a suitable attachment is clamped to the front end of the ram, the attachment consisting of grinding wheel spindle mounted in proper bearings. The wheel is used on the bottom end of the spindle, which is driven by means of a belt operating over a pulley located at the top end of the spindle. The motor is located on a bracket situated above the back end of the ram. This arrangement makes necessary the use of a cup wheel. Quite a common operation to be performed in this manner is the surfacing of pin slots in large manganese steel dredge buckets.

The use of the lathe for semi-precision grinding is limited almost entirely to special shape castings which have either a cylindrical, conical or flat surface which must be brought to a fairly smooth surface. The work is either mounted between centres or clamped to the face plate as usual. The grinding wheel is mounted on a spindle which is carried in a head fastened to the carriage of the lathe. The spindle is usually driven by means of a motor located on a bracket which is firmly fastened to the carriage. The bracket is situated a sufficient height above the carriage that the belt will operate satisfactorily. —*Grits and Grinds.*

ALUMINUM FUSE MAKING TROUBLES

ALL the difficulties in connection with the Russian shrapnel and high-explosive orders placed in the United States are not yet over, says a New York press despatch. Of total orders for 13,000,000 of these shells (excluding the Canadian Car & Foundry 5,000,000 shell order), probably not more than 3,000,000 have been shipped. Deliveries, however, are gaining in volume, and, while it is hardly likely that the orders will be completed within the contract limits, or by April 30, it is not unlikely that the end will then be in sight.

One of the principal causes of delay has been the employment of aluminum for the fuses, or for some of them. Aluminum, it appears, is subject to quicker fragmentation than brass, and for this reason the greatest trouble has been experienced in getting fuses made of the metal to function.

Under the adjustments made early last October, some of the aluminum fuses were changed to brass, and concerns which had been more successful in the fuse end of the business took over in some cases, parts of the fuse orders of others. From that time shipments, till then practically nil, have improved, but the delivery figure given above shows that there is still room for improvement.

High Pressure Steam Stop Valve Design and Construction*

By D. McNicoll

In what follows, investigation is made of various designs of steam stop valves, particular attention being given those accessory details which contribute to the general efficiency and operation safety of each individual unit, whether for service ashore or on board ship.

IN designing high-pressure steam stop valves, the essentials to be observed are tightness, reliability, simplicity, and safety. In small sizes not exceeding 4 in. or thereabouts and of single-beat type, these essentials are obtained without much call for special consideration, but as the sizes increase the design demands careful attention. In the succeeding columns an investigation of the various designs is contributed, and prominence given to details which affect what might be termed the general efficiency and safety of the fitting.

Fig. 1 shows a type of single-beat unbalanced stop valve frequently used as a boiler stop. The same design in more or less modified form is used throughout most main steam-pipe systems, being met with as an intermediate shut-off or bulkhead stop valve. The valve shown is of 8 in. diameter, the material of chest being cast-iron, internal parts gunmetal, and the working pressure 200 lbs. per square inch. In many instances chests of this size and for this pressure are made in cast steel, but provided the design is carefully observed the choice of material is optional. For larger sizes or higher pressures cast steel is desirable. Independent of pressure, wherever superheat is present, cast steel is essential, and the internal fittings in this instance should be of a high-tension bronze, perferably a nickel alloy.

The features in the design which call for special attention are stresses in the chest due to pressure; stresses due to hardening down; stresses due to expansion of spindle with valve shut; tendency of valve to rotate when steam is flowing through; liability to fracture of seat studs. In settling the thickness of body metal, the general method is to ensure that the aggregate section is such as to allow of a safe stress per square inch of section, but on investigation it is readily admitted that all parts are not equally stressed.

In Fig. 1, assuming that the pressure is present throughout the chest and acting at right angles to the plane of section shown, the stress on the part lettered A is much higher than on the other portions. By way of illustration:—The pressure on the upper half of the outlet and half the cover is approximately 8,950 lbs.; which stresses the section on the top left-hand side to 1,061 lbs., per square inch, whereas the average stress for the aggregate section is only 891 lbs. The cover, of course, takes a portion of the stress due to frictional resistance, and the tighter the cover nuts are screwed up, the greater the assistance given to the weaker section. In a sense this is "robbing Peter to pay Paul," as it simply puts up the stress on the studs.

The stresses resulting from excessive hardening down are in many instances exceptionally high, as is often proved by the burst condition of valve lids. This hardening down is due to an attempt to overcome leakage. It appears providential that the valve lid gives way in nearly every case, or otherwise there might be far more fatal accidents in this connection. Steel crossheads and turned pillars should always be fitted in preference to cast bridges, the latter being anything but safe, particularly in the larger sizes. There is no doubt that in valves over 4 in. diameter a great benefit accrues from the adoption of a flexible seating in conjunction with the solid face. This was introduced by R. R. Bevis, J. H. Gibson and Cockburns, Ltd. With this arrangement leakage from distortion is obviated, and, in addition, there are two faces, so that if one is leaking from any cause of distortion there is always the other one to fall back upon.

FIG. 1

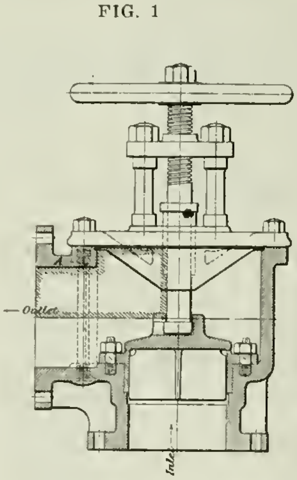

FIG. 2.

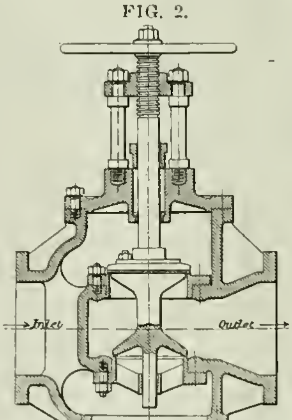

FIG. 3.

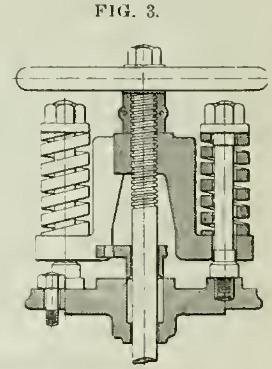

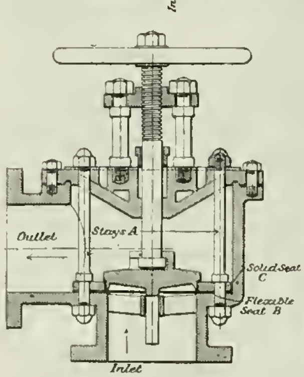

FIG. 4.

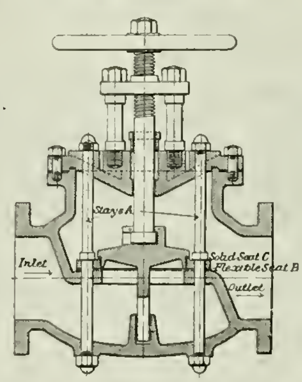

FIG. 5.

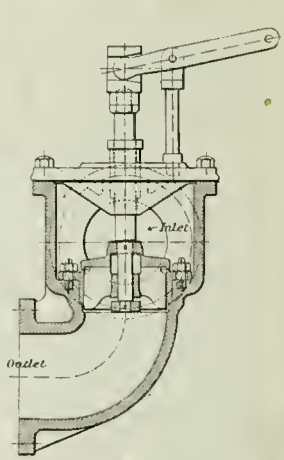

FIG. 6.

Shutting Down Hard When Cold

Another source of high stress is when the valve has been shut down hard when cold, and afterwards steam from other boilers admitted to the top of the body. Even with steam in the inlet side only a fair degree of heat is transmitted to the spindle. In each case the subsequent tendency to expansion puts a stress on all the parts. An actual experience of the author is illustrated in Fig. 2. This was a double-beat type of valve and the bottom seat was attached as shown. The valve was hardened down for a steam test, with the result that after the test a number of the manganese bronze studs from the bottom seat were found lying broken in the bottom of the chest, and all showed signs of fracture, the expansion of the spindle having caused this.

Apart from this, the design of seat is not to be recommended even if the studs do not give way, as the tendency thereby is to cause a leaky joint between chest and seat. Seats should be arranged where valves have to be hardened down so that this hardening tends to make the joint tighter, that is to say the gunmetal seat should be upon the top of the steel seat, and not below it as shown. One method of counteracting the damage from expansion is by fitting a spring crosshead. This is shown in Fig. 3, and is loaded generally from $1\frac{1}{4}$

*From a paper read before the Institute of Marine Engineers.

to 1½ times the boiler pressure per square inch of valve area, and a higher load than this cannot be put upon the valve spindle, no matter what purchase is used. In Fig. 1 stays are sometimes fitted as shown dotted. These only serve to stiffen the cover and, as will be noticed, still further reduce the section of metal at an already weak section.

The rotation of winged valves when steam is flowing is due either to a slight angle on the wings or to eddies in the steam. The valve can be prevented from rotating but to do this a pin must be fitted or other means adopted. The damage done to valves from this rotation is hardly credible, and calls for the adoption generally of pintle or centre-guided valves.

Valve Seat Fixing

The source of much trouble is the fracture of seat-securing pins or studs. In the large sizes it is quite inadmissible to drive the seats in and secure them by means of a pin or pins through the side of the chest and it is absolutely prohibited in all sizes when superheated steam is present, experience showing in this case that seats driven and secured by side pins become quite slack and allow leakage to occur. The seats in larger sizes are therefore secured in the manner shown in Fig. 1. The only way to avoid serious trouble with this design is to run a wire through the heads of all pins or through split pin holes, if studs are fitted. This prevents the fractured portions being carried to some part where serious damage may be caused.

The question of draining generally cannot receive too much attention, and means should always be provided for

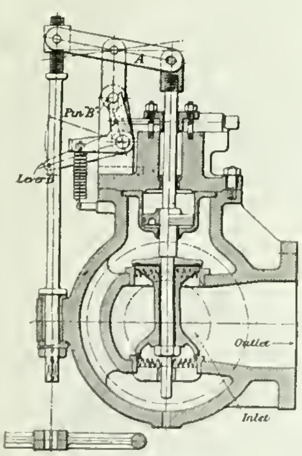

FIG. 7.

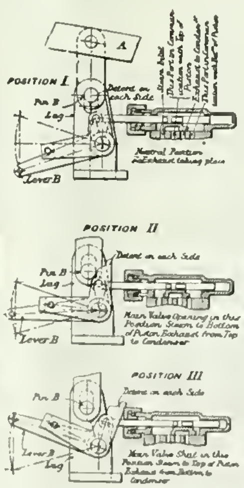

FIGS. 7a, 7b, 7c.

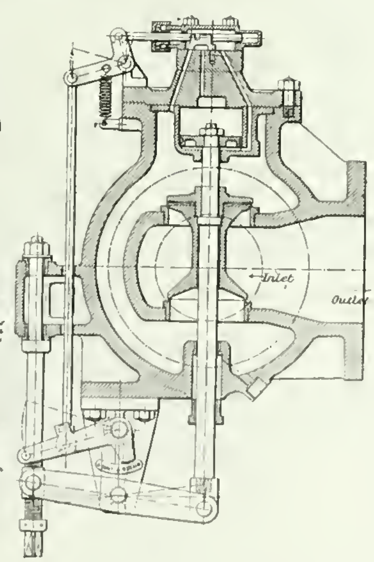

FIG. 7d.

efficiently getting rid of all water in both inlet and outlet before a valve is opened.

In Fig. 4 a type of valve is shown which it is suggested is an improvement on that shown in Fig. 1. The first feature that attention is desired to be drawn to is the method employed so that the cover may take up a share of the bursting pressure which acts at right angles to the axis of the spindle. This consists of a tapered spigot on the chest with a corresponding tapered recess in the cover, making a metal to metal joint. The stresses from hardening down and ex-

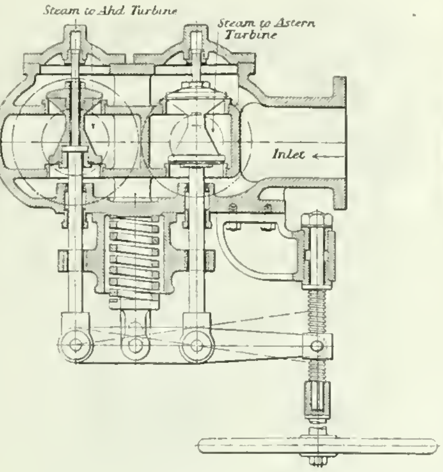

FIG. 8.

pansion are mainly taken up by the four stays A, which also serve to secure the seatings. With this arrangement no loose parts are situated inside the chest, with the consequent prevention of damage from this source. The valve is centrally guided thus preventing rotation. A flexible seating is shown at B and when this and the corresponding valve face engage, the solid seat C and its corresponding valve face are 1-100 in. open, so that when this latter seat and face engage the flexible seating is deflected 1-100 in. Fig. 5 shows the same design of valve as in Fig. 4, but of straight through or globe type: the design calls for the same attention as in the previous case.

Balanced Valves

In singlebeat valves of sizes over 4 in. and pressures in the region of 180 lb. and above, the valves are difficult to operate unless large diameter handwheels are fitted or handwheel spanners used to give the same effect or gearing introduced. The difficulty is due to frictional resistance in the screw and not to the direct load which, but for that resistance, would allow for quite a reasonably

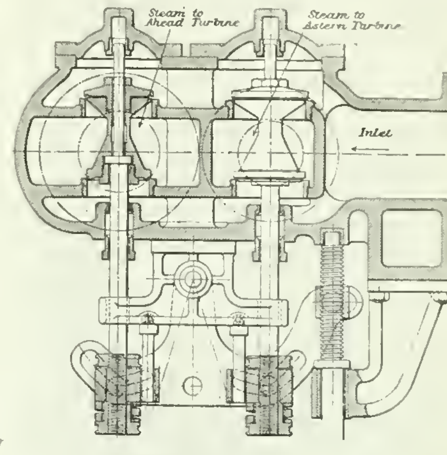

FIG. 9.

sized handwheel and comparatively quick-pitched thread in valves up to about 12 in. diameter. For regulating purposes large diameter handwheels or gearing are objectionable, not enabling the valve to be handled as expeditiously as is desirable. A compromise for this type of valve is effected and is shown in Fig. 6. A pilot valve is introduced and lifts first, balancing to a certain point the pressure in inlet and outlet branches. The main valve is then lifted against much less load. This fitting is extensively adopted, but occasionally trouble is experienced from the main valve pulsating or clattering, in reciprocating machinery, due to the fluctuating flow of steam—which causes damage te the internal parts.

Solid double-beat valves got over this trouble in the majority of cases and were perfectly balanced to all practical purposes, but they had one outstanding defect—they were rarely, if ever, steam-tight, which was very unsatisfactory. For reciprocating work this did not affect the steam consumption to any extent, as it was only when the machinery was at a standstill that leakage was occurring, and if a stoppage was of any length of time the boiler stop valves could be shut down. For turbine machinery, however, leaky astern valves can very seriously affect the economy. The leakage in the solid double-beat stop valve was due to differences of expansion between the double-beat valve and the seatings in the chest and could not be got over. A solution of the difficulty was ultimately found in introducing a flexible disc to one of the beats, and the names associated with this introduction were also Messrs. Bevis, Gibson, and Cockburns, Limited. This valve has been very extensively adopted in varying designs and is exclusively used for all regulating valves in His Majesty's Navy.

Double Beat Valve for Reciprocating Work

Fig. 7 shows a double-beat type of valve used for reciprocating work for regulating purposes and also as a throttle valve, doing away with the butterfly type. In this latter capacity a very light duty is thrown on any form of governing gear, while in larger sizes it obviates the necessity for employing a separate throttle engine, say of the Brown type. For ordinary opening and closing as a regulating valve the pin B is locked by the detents as shown, thus allowing the valve to be positively opened or closed. During these operations the control valve is in the neutral position, preventing steam from passing to the condenser. The operating piston has also inlet pressure on both sides of it, thus effecting a balance. The two beats of the valve have saw-formation spigots; this is to allow of close regulation, particularly where shafting is employed to bring the handwheel to a position not directly below the valve. The back-lash in this instance often allows a big jump to occur in the regulation, which is prevented with the design as shown. This jump is due to the following cause:—

With a valve of this design, that is, with steam entering outside the beats and the spindle going through the cover, there is in the first instance a closing effort due to the pressure on the increase in area of the top beat. The pressure on the area of the spindle where it passes through the stuffing-box is an opening effort. Generally the ratio of the former area to the latter is as two to one, with the result that when the valve is opened to an extent allowing half the initial pressure to be present in the outlet the efforts balance each other. A pound or two over this and an opening effort is present, with the result that the valve jumps open whatever play there is in the operating gear. With the saw formation of spigots this jump does not affect the revolutions to any extent. If instead of the spindle coming through the top of the cover it had come through the bottom of the chest the effort would have been a constant closing one, and there would be no necessity for the provision of the saw formation of spigot. Further on, valves with their spindles coming through the bottom of the chest are shown in Fig. 7d, 8, 9 and 10. The saw formation of spigots is a refinement to give close regulation from dead slow to full speed, as many doublebeat valves are made without this formation. When the valve is opened to any degree of regulation it can be shut and opened again by the throttle gear in the following manner: In Fig. 7a, b,c the throttle lever B is moved from position 7a to 7c. The control valve during this operation moves through position 7b, holding the main valve open till the detents have cleared themselves from the pin B, then with the throttle lever in position 7c the main valve closes—the levers swinging from the nut on the regulating screw. To open up again the lever B is returned to position 7a, the main valve opens up and the small tension spring returns the detent, again locking pin B and putting the valve into a position of positive control. This fitting has given general satisfaction and has been extensively adopted.

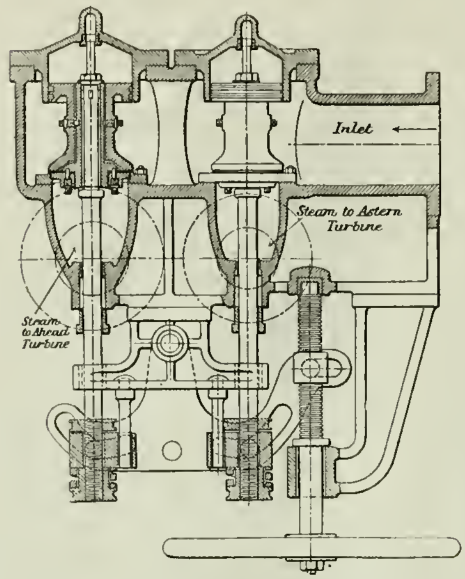

FIG. 10.

In future it is intended to make the last type of valve as modified and shown in Fig. 7d. A constant closing effort is present, which will allow of perfect regulation under all circumstances and will not necessitate the adoption of saw-formation spigots on the beats. The action under throttling conditions is similar to the former valve, with the difference that the slide valve is returned from position 7c to position 7b and 7a by the spring, assisted by the inlet pressure on the area of the slide-valve spindle where it passes through its stuffing-box.

Hardening-down stresses are alleviated by the expansion of the spindle under temperature. The illustration also shows the relative positions of ports and passages, and consequently gives a better idea of the connection between the positions of the controlling slide valve and the positions of the main valve than is shown in Fig.7.

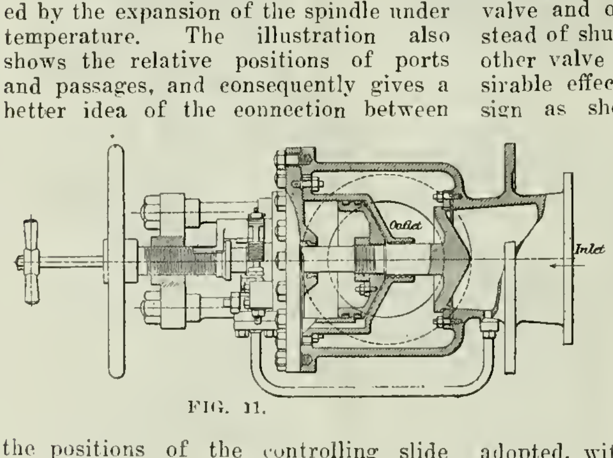

FIG. 11.

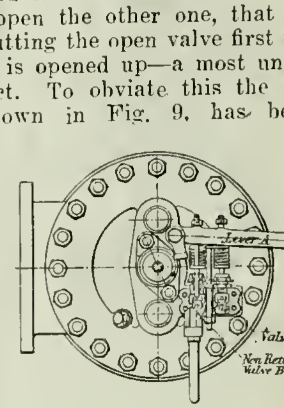

FIG. 11a.

To prevent water coming down between the spindle and stuffing-box of the main valve, as far as possible, the stuffing-box is kept high in the inside of the chest, and a drain-hole provided at the top of the packing to drain any water that may tend to accumulate there to the bottom of the chest. Provision is also made for taking away any drips that may come down.

In both the foregoing valves the design has been devised from the point of view that the relative positions of the indexes for both main and throttle valves at the starting platform are exactly similar to those where separate valves are fitted. A point of particular importance has also been carefully observed in the design, namely, that wear and tear have no effect on the efficiency of the gear.

Regulating Valve for Turbines

Fig. 8, page 10, shows a type of ahead and astern doublebeat regulating valve for turbine machinery, of which a large number have been fitted. With this arrangement one handwheel only is necessary. In a mid position both valves are shut, rotation in one or other direction opens either valve, the shut valve meanwhile becoming the medium of the fulcrum for the opening valve. In a design of this sort it is essential that the handwheel should be most clearly marked by arrows for rotation for ahead and astern. Not only should the handwheel be marked, but an index should be fitted with a pointer of considerable travel indicating quickly which valve is being operated and in what direction. This also applies to single regulating valves because, while in the majority of cases valves are shut by what is termed a clockwise motion, that is right-hand when looking on the handwheel, with the valve or extending spindle receding from the same, there are cases of extended spindles where the motion is clockwise looking in the opposite direction.

With the arrangement as shown in in Fig. 8 it is possible, if the spindle of the open valve seizes in the neck bush or gland and it is desired to shut this valve and open the other one, that instead of shutting the open valve first the other valve is opened up—a most undesirable effect. To obviate this the design as shown in Fig. 9, has been adopted, with most satisfactory results. Here the open valve must be positively shut to the point of the spigots entering the seats before the opposite valve can be opened. After this point the valve is closed and contact made with its seat by the pressure of steam on the difference of area of the two beats of the valve, plus the pressure into the area of the valve spindle where it passes through the stuffing-box. The springs on the spindles also assist this effort. No greater closing effort can be put upon the valve. In this respect it differs from the fitting shown in Fig. 7, where, of course, the valve can be hardened on its seat to any extent.

Another arrangement of balanced valves which has a much greater final closing effort, and consequently ensures tighter valves, is shown in Fig. 10. The valves are balanced by the control valve, which forms part of the spindle, first exhausting steam from the top of the piston. Another outstanding feature is the simplicity of the chest casting, particularly desirable in cast steel. The closing effort when the valves are shut is the pressure on the area of the valves. In these designs of double manoeuvring valves and valve as shown in Fig. 7b it will be noticed there are no stresses due to expansion of spindles.

Valve for Turbine Service

A valve widely adopted in conjunction with turbine machinery for both naval and mercantile work is shown in Figs. 11 and 11a. This fitting is a combined bulkhead shut-off and emergency valve. It also fulfills the function of a self-closing valve in naval work. For ordinary opening and closing the valve is operated in the usual way by means of a handwheel. In the larger sizes it is necessary to employ a handwheel spanner. When the main valve commences to open the collar on it has an inclined plane action on the lever A which lifts the spindle of the non-return valve B, allowing steam to pass to the top of the piston and check any sudden opening tendency. The leakage past the piston rings determines the opening speed of the valve. For shutting by throttle or emergency gear, the lever A is moved further, which opens valve C; this exhausts steam from the under side of the piston, when the pressure on top of it closes the main valve. On returning the lever the main valve slowly opens up to its previous amount of lift. For naval work, where there are two or more bulkhead valves, if the pipe on the inlet side of one valve is shot away the valve is supposed to self-close with the reverse flow of steam. When this occurs the non-return valve B also closes. The efficiency of this fitting was lately demonstrated unintentionally in a fast ship of war. An exceptionally heavy sea broke over the vessel, the turbines stopped, and for some time no explanation was forthcoming; ultimately it was found that the sea had carried some gear against the deck emergency lever and moved it into the shut position, with the result that both bulkhead emergency valves were effectively shut.

CUNARD SHIPS IN U.S. YARDS

THE placing of contracts for merchant vessels by the Cunard Steamship Line has ben noted from time to time within the past few weeks. An official statement has now been issued by James McNaught, of Esplen Sons & McNaught Inc., naval architects, who have acted for the Cunard Co., in placing orders for boats with American shipyards: "Details of the Cunard shipbuilding cannot be given, as the Company is under the British censor, but I can say that the Cunard construction program is the greatest in the history of shipbuilding. Orders are being placed in almost every available yard. The Bethlehem Steel Co. is to build ships at the Maryland and Fore River yards and at the Union Iron Works. The Todd Shipyards Corporation has orders for six ships of 7,500 tons at the Seattle yard. The Sun Shipbuilding Co. also has orders."

"Ships to be built in the United States vary from 7,500 tons to 12,500 tons. Several steamers are being built for the Cunard Co. in England, and at least one will have turbo-electric propulsion. At present England has three or four ships under construction of that class. Trials of this power have been sufficient to justify installing this machinery on one of the big Cunarders. I cannot give the size of these vessels. One of the small steamers with the new power will be of 5,500 tons. They will all be capable of high speed. We have found that the electric installation can be so constructed as not to reduce the carrying capacity, and need not add to the work of the vessel."

EMPIRE ZINC OUTPUT

THE annual meeting of the Amalgamated Zinc Co., as reported in the London *Statist*, shows what changes the war has forced. The properties are in Australia. Before the war the company was producing zinc concentrates at the rate of about 150,000 tons per month, the zinc contents averaging 49 per cent., or, say, 75,000 tons of pure metal. These concentrates were shipped to Germany, where they were treated for the production of commercially useable zinc. The Amalgamated Co. has just about installed its first unit of plant for electrolytic zinc production, which has a capacity of between ten to twelve tons of electrolytic zinc per day, or, say, 3,000 to 3,500 tons per month, which will require about 4,000 horse-power. In order to warrant the establishment of this plant, New Zealand made a contract for the disposal of the product of the new company for ten years to the Imperial authorities under a guaranteed price.

The Consolidated Mining & Smelting Co. of Canada has been going through the same process, having made a contract for its output with both Great Britain and Russia. It is understood that the Consolidated Co. is now turning out some 35 tons of commercial zinc per day, which is being gradually increased. The company, through its ownership of the West Kootenay Power & Light Co., controls some 40,000 horse-power, which is available for this and similar purposes.

INDIA BUYING STEEL IN U. S.

MITSUI & CO. will send two steamships from Seattle to India this spring, each loaded to capacity. The Amogisan Maru will sail this month direct from Bombay with approximately 3,000,000 feet of lumber, and the Niels Nielsen will sail in May with 8,800 tons of steel and lumber for Calcutta and Bombay, says the Seattle *Times*.

Traffic between Great Britain and India via the Suez Canal has ceased because of war conditions, and India is now looking to the United States for steel and tin products as well as lumber. News of the decision of Mitsui & Co. to send the two vessels to India this spring was obtained from the corporation's Seattle headquarters.

In the last few weeks a number of inquiries have been received in Seattle as to the possibility of getting space in vessels for India. The inquiries relate chiefly to steel, tin plates, structural products and lumber. These shipments are needed in India for ordinary construction work. Before the closing of the Suez Canal to traffic, India obtained its steel and similar products from England.

CANADIAN GOVERNMENT RAILWAYS

STATISTICAL information regarding the Canadian Government railway is contained in the annual report of the Railway Department, issued at Ottawa, on March 8. The total expenditure, including the Quebec Bridge, amounted to $43,-627,328, of which $23,902,068 was charged to capital, $19,408,780 to revenue, and $1,716,051 to income. The outlay on the Transcontinental was $11,488,980 on the Intercolonial $21,702,441, and on the Prince Edward Island line $1,350,472.

Revenue derived from Government railway and canal works aggregated $18,-874,630, of which over eighteen millions came from the railways. Before and since Confederation, Canada has spent $118,-614,725, on its canals and $377,146,699 on its railways. This includes the Quebec Bridge and subsidy to the C.P.R. main line.

The Intercolonial had a good year. Its earnings were $14,068,791, and working expenses $12,551,495, producing a surplus of over one and a half million dollars. On the Prince Edward Island Railway there was a deficit of $154,093, and on the International Railway—a leased line in New Brunswick—$12,027, exclusive of $90,000 paid on interest.

The mileage of Government roads is 1,-527 an increase of 78 in the year. The number of passengers carried was 412,-535 a decrease of 10,961.

Black Color on Brass.—A black color on brass can be obtained by the use of the following solution: White arsenic, 2 ozs.; potassium cyanide, 5 ozs.; and water, 1 gallon. This is used as a hot dip without current. The work is immersed in the mixture, either suspended by wires, or in a basket, the solution being contained in an enameled tank or container.

MACHINISTS' INSTRUCTION COURSE—XV.

By J. Davies.

SCREW threads are produced commercially in a variety of ways, involving different types of machines, either specially designed or else suited for using accessory devices, such as taps, die-heads, etc. Occasions still arise where the use of a screw-cutting lathe is the only means of performing the work; the following remarks applying more particularly to the actual handling of the lathe, change gear calculations having been dealt with in previous articles.

Cutting a Vee Thread

When a screw-thread is to be cut, the tool is ground and shaped to suit the

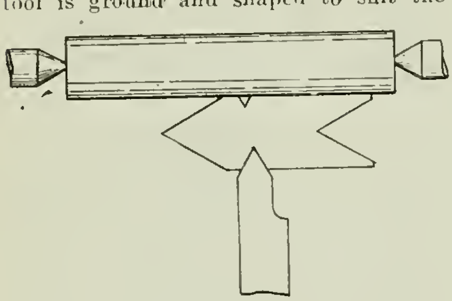

FIG. 53.

finished thread, the side faces forming an angle of 60 deg. This angle is tested by using a thread gauge, shown in Fig. 53. The gauge should be held so that the back edge of it lies flat against the work while the point of the tool is adjusted to fit the notch in the front of the gauge. It is sometimes convenient to hold the gauge as shown in Fig. 54; when one edge of the tool is properly set, the other edge will be at the correct angle, providing the tool is properly ground.

In cutting a vee thread the tool rest should be moved around 30 deg. for American threads and 27½ deg. for Whitworth threads, this being half the angle of the thread. The reason for this is that when a cut is taken, the tool cuts on one side only, which gives a cleaner and better thread than is the case when the tool-rest is set at right angles to the lathe centres. In the latter case the tool must cut on both sides at once, which means a smaller cut and a rougher finish. (See Fig. 55.)

Before commencing the cut, care should be taken that the tool is securely fastened in the tool-post, and that the lathe-dog is firmly secured to the work. Select a lathe-dog that fits the work as closely as possible. File or chip a flat spot on the work for the point of the set-screw, unless the nature of the work prevents this being done. The feed should run from right to left for cutting a right-hand thread and from left to right for a left-hand thread. In putting on the cut, it will be found very convenient to run the tool rest up against a stop, Fig. 56, at every cut. By this means we return the tool exactly to the position it was in when we started the previous cut, and then by simply turning the stop screw back an amount equal to the cut required, there is not the same necessity for observing the graduations marked on the cross-feed screw, or the more cumbersome method of chalking. This stop is not usually fitted to the lathe by the makers, but it is a very simple matter for any mechanic to fit one up for himself.

Engaging the Nut

In cutting a short thread, the tool is often carried back to its starting place by means of a cross belt which reverses the lathe. In a very long job this is a serious waste of valuable time. The quickest method of taking the saddle back is by hand, but in doing so we must locate the exact time and place for putting in the nut for the next cut.

(1) When the number of threads on the work can be divided by the number of threads on the leading screw without a remainder, the nut may be engaged at any time or place.

(2) When the leading screw makes two or three or any number of complete revolutions to one revolution of the job, put a mark on the job or face plate; then every time that mark comes to a given place the nut can be engaged, or in a slow-running job put a mark on top of the face plate and another on top of the leading screw; then when both marks are on the top together you may put in the nut to start another cut, providing the carriage is touching the tailstock or some other definite starting place.

In all other cases put down the pitch in fractional form reduced to its lowest term. The numerator will indicate the least number of complete inches that the carriage must travel, after taking the nut out of gear with the leading screw, before it comes to the right place to put it in again.

Starting the Cut

Put the carriage against the tailstock

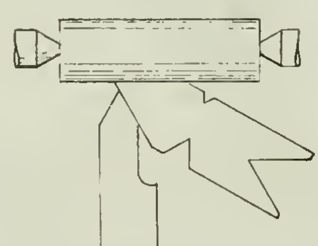

FIG. 54.

for a starting place, and measure on the lathe bed the required number of inches, or some multiple of the same, according to the length of screw to be cut. Stop the lathe at this mark, and run the carriage back to the starting place for a fresh cut. After taking the first cut, measure the thread carefully to see if the lathe is cutting the right pitch. In thread cutting it is important that the tool should be set exactly at the centre. If the tool is set too high or too low, it will make an imperfect thread. When the tool commences to cut it is sprung to one side a little until it is advanced up the thread far enough to cut on both sides; this causes a thick thread on the end, which is apt to deceive one when fitting it into place. To avoid this, leave the portion to be threaded a little longer

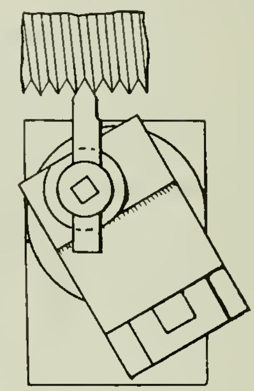

FIG. 55.

than the length of the thread and cut off the thick end the required length after the screw is finished.

Cutting Multiple Threads

Select the wheels so as to have one on the lathe spindle that can be divided into two or three equal parts as required, and proceed the same as for single threads until one thread is cut, with the exception of the finishing cut. Chalk the bottom of any one space on the spindle gear, and also chalk the tooth of the change gear which meshes with this space. If it is a double thread, count half the number of teeth on the change gear and mark in the same way. Adjust the quadrant or swing plate so that the second marked tooth will mesh in the chalked space on the spindle gear, and proceed to cut the second thread. When taking a finishing cut, take the screw out of the centres, so as to be able to move the saddle back without moving the tool, drop the quadrant and mesh the gears at the next chalk mark and finish the second thread. The same method will do for three or more threads. This is the generally accepted way for cutting double or triple threads, although there are other ways which, under favorable circumstances, are quicker and more convenient. For instance, a double or triple thread can be cut at one operation by a tool that is filed up with two or more cutting edges to suit the required pitch, or on some jobs, such as cutting a one-inch pitch with a half-inch lead-screw, a cut can be taken from each thread alternately without changing the

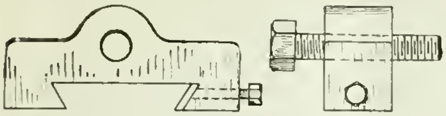

FIG. 56.

gears by engaging the nut when the work has made half a revolution.

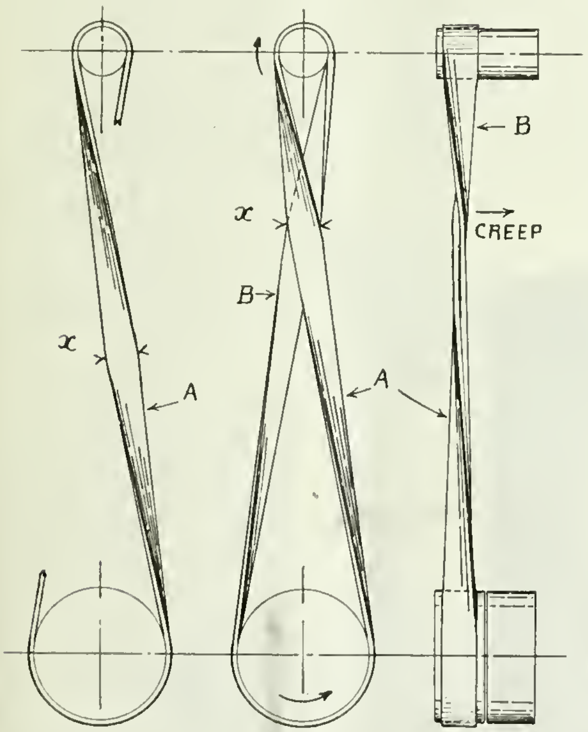
Left-hand Threads

In cutting a left-hand thread, the direction of the travel of the tool is generally reversed, either by reversing the quadrant or putting an extra wheel in the train of gears. This method is not always the best, as, for instance, the cutting of a left-hand thread inside a long sleeve can be done by reversing the lathe and commencing the cut at the same end, as a right-hand thread would be started ordinarily. . The advantage of this is that the lathe hand can see exactly what the tool is doing before it has time to do any damage, as would happen if the nut were engaged with the shaft at the wrong place, a thing which the best of lathe hands will do sometimes. The disadvantage is that the cut has a tendency to unscrew the chuck off the lathe spindle. When a left-hand thread is to be cut in this way, the chuck should be put on with a slight bang to insure that it will not easily unscrew itself.

BELT TROUBLE

Question.—I am having trouble with a belt drive which I would like you to advise me about. The line shaft is perfectly straight and level and the machine is also level and properly squared up with the shaft. The machine pulley is 15 in. dia. and the line shaft pulley is 6 in. dia., with 6 ft. centres. When the belt is crossed one way it runs over on the tight pulley and will not stay on loose pulley without belt shifters and when crossed the other way it runs over on loose and will not stay in tight pulley. I would appreciate an explanation so that I may cure the trouble if possible.

Answer.—The trouble is due to one of the following conditions being near the limit, with regard to the others:—The centres are too close, or the belt is too wide, or the difference in diameter of the pulleys is too great. The accompanying diagram shows how these points affect the behaviour of the belt as described. The arrows indicate direction of movement, A being tight side of belt, and B the slack side. Sketch (a) shows the shape of A before B is in position. It will be noted that the widest part (x) is at a point midway between where the belt leaves the pulleys. When the belt is all on, the two sides press against each other so that point (x) is moved upwards, as shown in sketch (b). The tendency of A is therefore to twist in a left-handed direction, pressing B away from the reader, the reverse action being exerted by B, but the fact that A is the tight or driving side of the belt causes B to yield more than A, so that in sketch (c), side B will run onto the tight pulley with a gradual creep to the right as complained of. If the belt be crossed on the opposite hand, the reverse action will take place, as complained of. In order to dispense with belt shifters, it would be necessary to crown the faces of the tight and loose pulleys as much as possible, run with a thinner and narrower belt, increase the distance between centres or increase size of pulley on line shaft. By trying these suggestions as far as possible in rotation you should manage to cure the trouble.



BELT TROUBLE DIAGRAMS.

Foundry Tumbling Barrel

SOME time ago, having a very large quantity of small castings to supply, says a writer in the *Foundry Trade Journal*, we decided to build a small rattler or tumbling barrel, as the large iron ones caused a great deal of breakage. The measurements of the new one were 15 ins. inside and 3 ft. long, this holding a barrow-full at a time. The

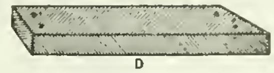


FIG. 3.

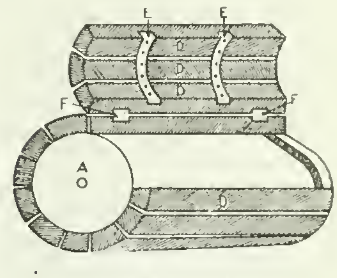
method was as follows: Cast two discs 15 ins. dia. and 1 in. thick, with a spindle as shown at B, Fig. 1. Make two wood discs and bolt on to face at CA,



FIGS. 4 AND 5.

Fig. 2. This method saves drilling and machining, for the wooden bars, D, Fig. 3, can be screwed on to the disc. The lid, Fig. 4, is of three bars screwed on to sections of wrought iron bent to cor-

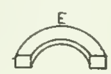


FIG. 6. FIG. 7.

rect angle at E and D, Figs. 4 and 6, and mounted as shown in Fig. 5 by hinges F. Next cast two blocks for bearings, and drill through as shown at G.

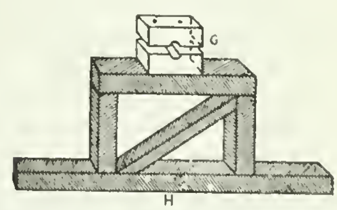

FIG. 8.

Fig. 7. The standards, H, Fig. 8, are of timber, 3 ft. by 4 ft.; these can be bolted to the floor.

The whole thing was put together by

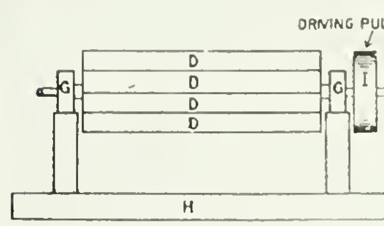

FIG. 9.

a carpenter, and cost about $15. It can be attended by any lad, and proves a most serviceable and cheap tool for very light and small castings.

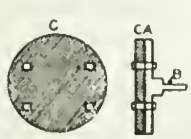

FIG. 2.

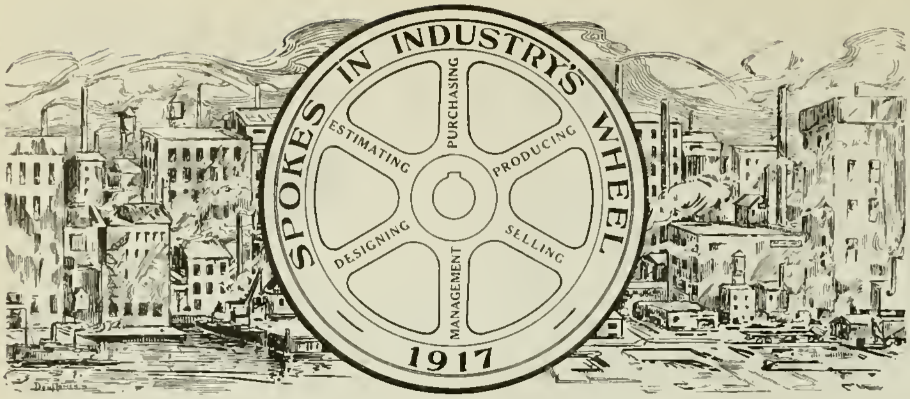


The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

WILLIAM MARTIN McROBERT

At a time like the present, when surmises regarding future conditions are being made on all sides, and the probability of intensified competition looms up as a result of Britain's industrial awakening, it is reassuring, to those solicitous of Canada's future, to know that a prominent feature of the rising generation of engineers is the large number who, by birth, ancestry, or educational experience, have been able to absorb to a large degree those characteristics of the British race which, in view of future possibilities, may afford apt illustration of "diamond cut diamond."

A prominent English engineer, with world-wide experience, once remarked that Scotland was all right for breeding men, but was no use for feeding them. There may or may not be any truth in the latter part of the statement, but many of our readers who are acquainted with William Martin McRobert, sales engineer of the Galt Foundry Co., Galt, Ont., will be in perfect agreement that a deal of truth is contained in the first part of the remark.

Mr. McRobert is a native born Canadian, having first gazed upon the maple leaf in the immediate environs of London, Ont., in the year 1876. When three years of age his parents returned to their native land and settled in Aberdeen, where our "Spoke" spent his early years, his education being received at Aberdeen Grammar School and Gordon's College. That he had early absorbed a due share of that determination and tenacity which are so authentically attributed to residents of the "Granite City" was evidenced by his decision to go through the mill as an apprentice engineer.

Much has been written and said regarding the value of experience in the eyes of Scotch people, and a recital of apprenticeship conditions under which our friend gained his knowledge of wheels and things may account in some measure for this trait. Commencing early in his teens, he started work at 6 a.m., quitting at 5.30 p.m., with two stops for breakfast and dinner. The remuneration offered seems to have been in inverse ratio to the hours worked when judged by Canadian standards. For instance, we are informed that the young apprentice was rewarded with the sum of 75c per week the first year, with annual increments of 25c per week up to the sixth year. Technical education was obtained through evening studies at the local Technical School over a period of four years.

These conditions easily made it a case of the survival of the fittest, a further

WILLIAM MARTIN McROBERT.

test of tenacity being the necessity of making up all lost time as double hours before the youthful journeyman received the coveted "lines," i.e., certificate of apprenticeship. Some certificate!

Dalgety Brothers, Aberdeen, was the firm where this training was undergone, and a short time afterwards our friend entered the service of the "P. and O." line of steamships, climbing through the various grades to the rank of senior engineer, for which it was necessary to pass the Board of Trade examination for first-class engineer. A decade spent on ocean mail steamers familiarized Mr. McRobert with the operation and upkeep of power plant equipment to a degree seldom obtainable in land installations. The necessity for avoiding breakdowns at all costs, and the limited facilities for effecting repairs in case of accident developed an alertness and self-reliance which is typical of the modern marine man. It is not surprising, therefore, that when, after ten years of sea life, our "Spoke" decided to settle in the land of his birth, he was appointed chief engineer of the Canada Foundry Co., Toronto, a position which he held for three years before transferring his services to Gunns, Ltd., Toronto, in a similar capacity, but with the additional duties of master mechanic.

As sales engineer for the Galt Foundry Co., Mr. McRobert finds ample opportunity for drawing on his wide experience, his energies being devoted to the development of the Galt sprinkler stoker and the McNaughton grate bar. No combination of circumstances is likely to offer very great difficulty in the application of his personally acquired knoweldge of things mechanical. In the course of his travels Mr. McRobert has had frequent opportunity of studying industrial practice in nearly every civilized country, having, with the exception of Northern Europe and South America, visited every part of the globe. His travel record includes over 70 passages through the Suez Canal, and also coast to coast trips in Canada and United States.

Mr. McRobert's home life is centred in Toronto, where he resides at 92 Symington Avenue, his son being a student at Toronto Technical School preparatory to following a kindred career to that of his father. His experience in occasionally isolated situations gave Mr. McRobert more than ordinary opportunity for appreciating the value of technical study; in fact, he considers that for any engineer or mechanic having ambition to advance in his profession it is imperative that he should keep abreast of the times by combining with his practical knowledge the study of reliable engineering literature, also the reading of the many interesting and instructive articles appearing in the current issues of mechanical trade journals.

Questions.—What would be the pressure at the discharge end of a lubricating hose on a boring machine using gravity feed, the supply tank being located 30 feet above the floor?

Answer.—A column of water one foot in height and having a cross sectional area of one square inch will weigh .434 lbs. As the height of the discharge above the floor will be about 3 feet, the actual head of water will be 27 feet; therefore, the pressure at the machine will be approximately $.434 \times 27$ equals 11.7 lbs. per square inch.

PROGRESS IN NEW EQUIPMENT

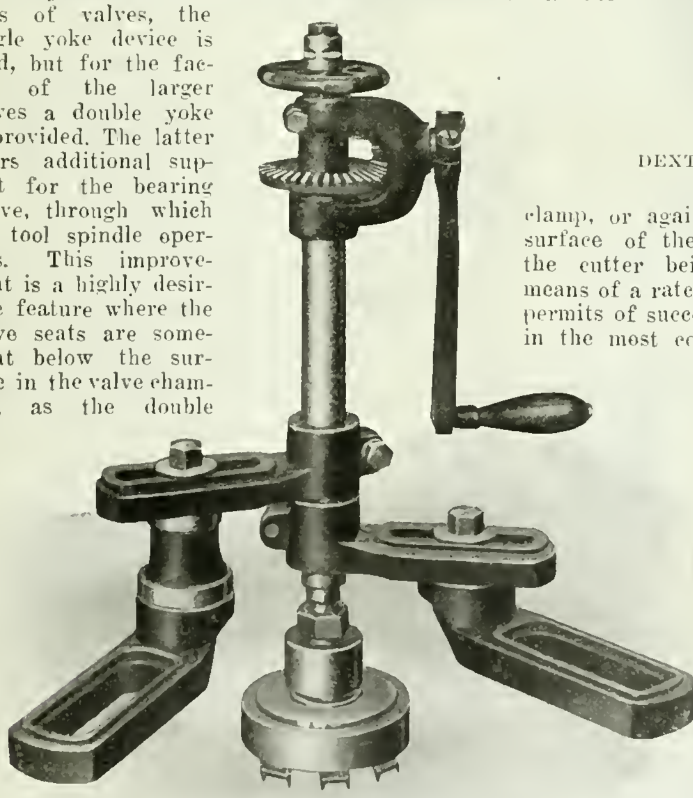
A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

PUMP VALVE RESEATING MACHINES

ONE of the chief factors in the maintenance of high efficiency pump operation is that of the care given the upkeep of the various valves forming part of each pump unit. The effect of wire drawing and the presence of grit in the water soon result in poor fitting valves; it is, therefore, essential that the accuracy of the latter and their seats be maintained. Where the failure of a pump to effectively perform its allotted task means the temporary shut-down of a portion of a plant, the question of prompt repairs is a very important feature.

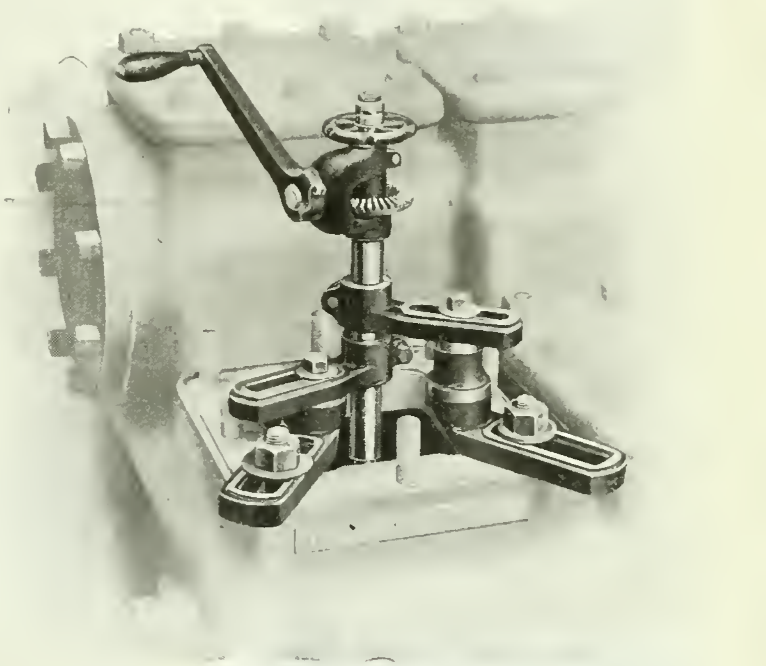
The accompanying cuts illustrate several applications of the Dexter pump valve reseating machines, and feature their usefulness in the repairing of various types of pumps now in service.

Simplicity of construction of this apparatus is coupled with high efficiency of action; a feature of their operation being the ease with which they are attached to any valve chamber. For the smaller sizes of valves, the single yoke device is used, but for the facing of the larger valves a double yoke is provided. The latter offers additional support for the bearing sleeve, through which the tool spindle operates. This improvement is a highly desirable feature where the valve seats are somewhat below the surface in the valve chamber, as the double clamping facilities offer increased rigidity when the machine is in service. For the smaller sizes, the cutter is driven direct by a handle attached to the spindle, and is operated in a direction parallel to the face of the cutter. In the large sizes, where more power is required, the cutter spindle is revolved by means of beveled gears working in a bracket secured to the upper end of the bearing sleeve; in this case the power handle operates at right angles to the cutter face.



DEXTER PUMP VALVE OUTFIT DHG.

Where the arrangement of the valves does not permit of using the long bearing sleeve, special devices are provided for the facing of the seats, the pressure being obtained by means of adjusting screws operating in the clamp, or against the opposite surface of the valve chamber; the cutter being revolved by means of a ratchet handle, which permits of successful application in the most confined locations. The type of cutters used on these attachments are made of best quality steel, and are otherwise designed to meet their special work. The action of the cutter leaves the surface of the seat perfectly smooth and free from chatter marks. Other designs of Dexter reseating tools meet the repair needs of valves on the high pressure hydraulic pumps installed in connection with shell forging plants.



DEXTER DOUBLE YOKE PUMP VALVE RESEATING MACHINE REFACING SUCTION VALVE SEAT.

Darling Bros., Montreal, manufacture the foregoing products for Canadian distribution.

CONVEYOR TYPE AUTOMATIC HEATING FURNACE

THE accompanying illustration shows a unique type of gas or oil-fired furnace which has recently been built by Canadian Hoskins, Ltd., Walkerville, Ont., for the purpose of heating base plugs for

DEXTER PUMP VALVE ATTACHMENT RATCHET OUTFIT R.

the press. The moving hearth is in the form of an endless chain, built up of four sections, side by side, the sections being advanced one-quarter of the pitch

DEXTER IMPROVED TYPE PUMP VALVE CUTTER.

so as to stagger the joints evenly over the surface.

The chain links are protected by nonpareil cork brick, on which the work rests as it passes through the furnace. At no time does the chain come in direct contact with the flame. Each link is in the furnace for only one-third of the time for each circuit, and does not attain a higher temperature than 900 deg. F., being cooled during the other two-thirds before entering again.

The furnace chamber is divided into two sections—the first one acting as a preheater, by varying the temperature of which the output can be increased or decreased to meet requirements. With

AUTOMATIC FURNACE WITH CONVEYOR TYPE OF HEARTH.

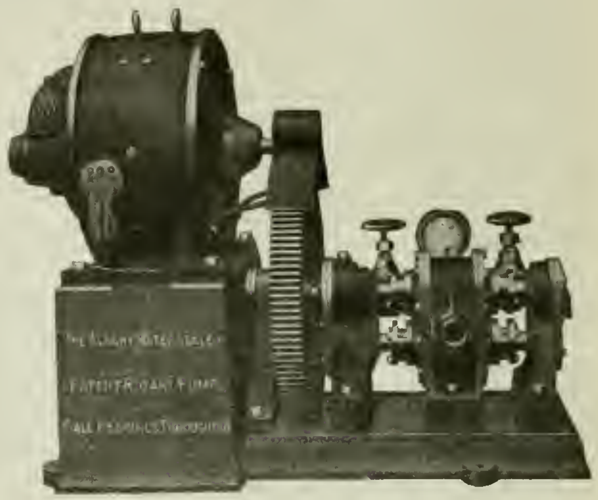
this chamber fairly cool, the plugs may pass through as slowly as one every 30 sec., whereas when heated up to 1,800 deg. F., a rate of one plug every 2 sec. can be delivered at the exit end of the second chamber, which is maintained at the required temperature, irrespective of the speed at which the work passes.

WATER SEALED ROTARY PUMP

THE Albany Pump Co., Toronto, are now building the Albany patent water-sealed rotary pump, which heretofore has been imported from London, England. The general design of this pump is similar to other rotary pumps on the market, in that it consists of a metal casing, inside of which revolve the impellers or wheels. The most important feature of this pump is the fact that slips and leakage have been reduced to a minimum by the introduction of grooves cut along the faces and edges of the teeth, so that in rotating a body of water lodges in the grooves forming an absolutely sealed water-tight joint or cushion between the casing and the rotating rollers, thereby producing an efficient vacuum. Centrifugal force also adds greatly to the efficiency of the pump.

The pump is suitable for dealing with all kinds of liquids, the wheels and casings being made of different metals according to work for which it is required. Quite recently a pump was installed in Toronto for handling asphalt, which shows the wide range of application of such a unit.

The pump is designed for motor drive through a gear wheel and raw hide pinion, also for belt drive or by gasoline engine. In the latter case, the pump drive is through a roller chain, and not direct connected as formerly. The speed of the pump is the same for the medium and larger sizes, being 200 r.p.m., and



WATER-SEALED ROTARY PUMP.

the various outputs range from 700 to 60,000 gallons per hour. The speed of the smaller sizes, however, varies, the minimum capacity of the small pumps being 60 gallons per hour.

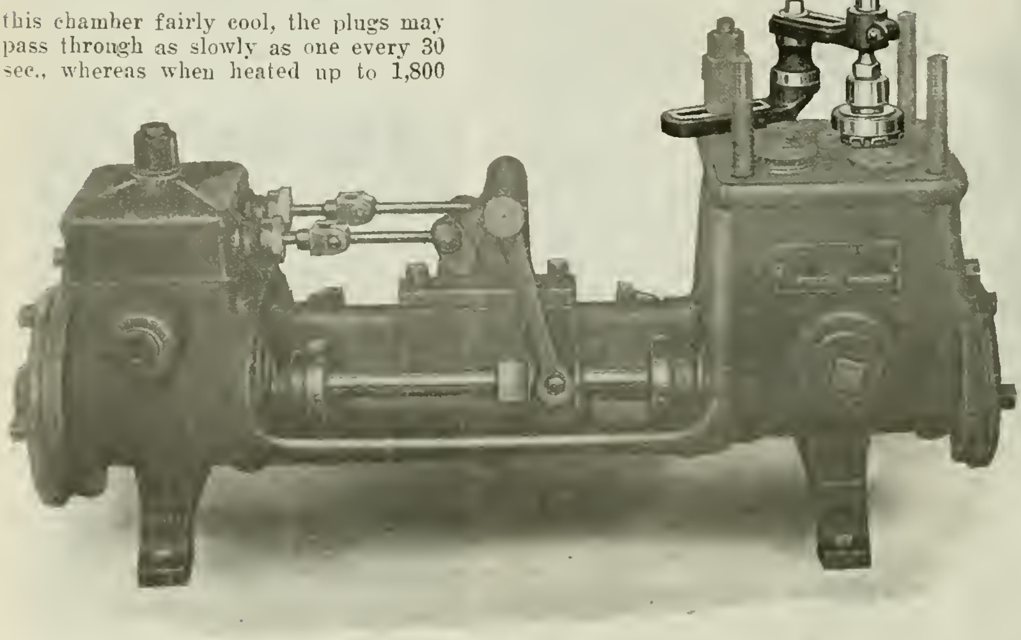
The "Albany" pump has achieved considerable success in pumping fuel oil, and several outfits have been placed in H.M. Dockyards, and are being largely used by the British and French Admiralties. After an exhaustive test, several of these pumps have been installed in H.M. submarines for pumping water from the trimming tanks.

AUTOMATIC TEMPERATURE CONTROL

THE demand for automatic apparatus wherever applicable has led to the development of automatic temperature controllers for gas and oil-fired and electrically-heated furnaces, a comprehensive line of these devices being now manufactured by the Bristol Co., Waterbury, Conn.

The principle on which these new devices are designed is to employ three elements—the measuring element, the contracting element, and the operating element.

The measuring element consists of various types of Bristol electric pyrometers and thermometers. The controlling element is combined with the



DEXTER SINGLE YOKE PUMP VALVE RESEATING MACHINE REFACING DISCHARGE VALVE SEAT OF DUPLEX STEAM PUMP.

measuring element, and consists primarily of an electrical contact closing device, which operates at predetermined high and low temperatures, thus closing

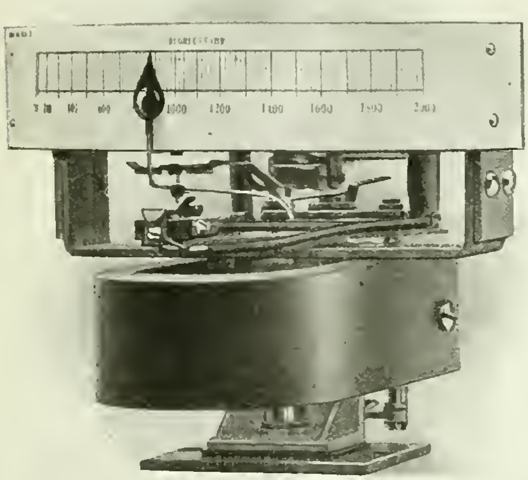


FIG. 1—INTERIOR OF CONTROLLING ELEMENT.

or opening electrical circuits which energize or disconnect the operating element. The interior of the controlling element is shown in Fig. 1, from which it will be seen that the indicating arm is completely insulated from the operating circuits, the contacting device being frictionless. These controllers are furnished for all temperatures up to 3,000 deg. F., with high resistance movements for use either with base or rare metal couples.

The operating element consists of the device which actually regulates the heat supply in the furnace; as, for instance, in the case of a gas-fired furnace, a pair of electrically-operated gas and air valves, and in the case of an electric furnace, it consists of a special relay switch opening and closing the circuits of the heating element of the furnace.

An interior view of a vapor-type thermometer-thermostat is given in Fig. 2, complete with sensitive bulb, this type of instrument being adapted for use

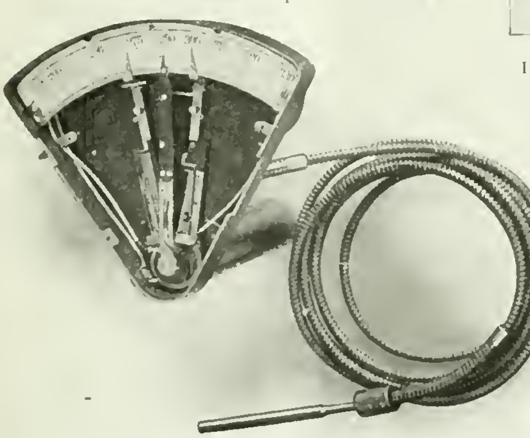

FIG. 2—INTERIOR VIEW OF VAPOR TYPE THERMOMETER-THERMOSTAT.

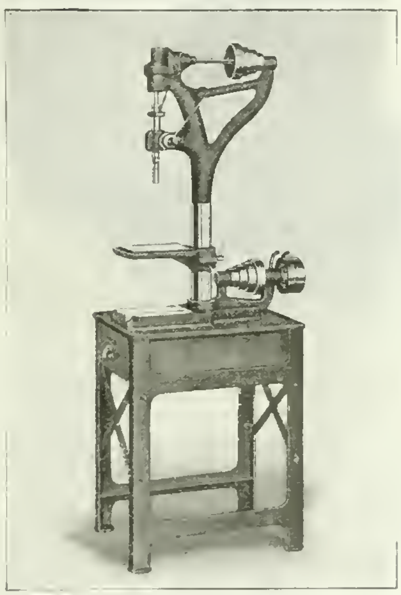
with a special relay switch, which is used when these instruments are employed for controlling temperatures in electric ovens and furnaces. The special design of contact closing device shown has proven very practicable and durable in long continued service. Both high and low contacts are shown in this illustration, but when used with the maker's automatic electrical controlling valves for both gas and air supply only one contact is required.

HIGH SPEED BENCH DRILLING MACHINE

THE machine shown in the accompanying illustration has been designed with the object of providing a more convenient and useful article of its kind than has heretofore been offered to manufacturers. The machine itself is a separate unit, and when combined with the bench as shown, it is readily adapted to motor drive, the motor being placed underneath the bench.

The spindle is a steel forging, counterbalanced, and gives very long travel to the drill, having an adjustable stop collar and



HIGH SPEED BENCH DRILLING MACHINE.

drift hole below the ball thrust bearing. A No. 1 Morse taper hole is provided in the lower end of spindle, while the column, which is well braced to insure stiffness, is well socketed into the base. The base is accurately planed and provided with two tee slots.

No babbitt is used in the construction of this machine, all bearings being fitted with split bronze bushings. The bevel gears are eight pitch, machine cut, the pinion being of raw hide to insure quiet running at high speeds. The maximum spindle speed is 2,400 rev. per min. Principal dimensions are: Swing, 10 in.; size of table, 8 x 10 in.; max. distance table to spindle, 14 in.; bed to spindle, 18 in.; spindle dia., ⅝ in.; net weight, 130 lbs.

The Charles Stecher Co., Chicago, are the builders of this machine.

TAPPING MACHINE

THE tapping machine illustrated in the accompanying cuts has been designed and built by the H. E. Harris Engineering Co., Bridgeport, Conn., for the express purpose of overcoming objections to the use of tapping machines which in many cases are productive of broken taps, spoilt and oversize work, etc., most of which can be traced to errors in alignment, inertia of reversing parts, and floating holders. The efforts of the builders have been to preserve the alignment of the tap with the work, reduce the shock of reversing the tap to a minimum, render easy continuous tapping to an exact depth, provide a constant non-slipping drive for the toughest work within its capacity, eliminate "drag" or lengthwise pull on the tap, supply an ample supply of oil to the wearing parts while keeping frictions and belts dry, and make it possible for an inexperienced operator to do good work.

Special attention has been paid to elimination of excessive tap breakage and the production of uniform tapped holes in this machine, at the same time giving maximum production by allowing the operator to use both hands to place and to remove the work, and to use them for this purpose only, making only short rapid movements, the operator being protected from undue fatigue, as he or she may stand or sit in a comfortable position while working, and may shift from one position to another without interrupting the output.

The tapping head is mounted permanently upon the bed, and consists of the tapping head castings, in which are clamped two bearings, one in each pillar. These bearings carry the rotating tapping spindle in their bore, providing an extra long bearing. Externally upon the portions extending inwards from the pillars, they carry the forward and reverse belt pulleys, acting as studs for them to rotate upon and also as a thrust bearing for them. These belt pulleys are bored on the inner surface of the rim to act as the internal members of the tap driving clutches. The external members of the clutch are carried by a spider mounted permanently and centrally on the tapping spindle, and are provided with a slight lengthwise movement with the spindle, to permit change from forward to reverse pulley clutches and vice versa. This clutch spider is made entirely from pure aluminum to insure lightness, and the tapping spindle is of high grade tool steel, so that the diameter may be kept to minimum size and maximum with the least amount of weight. The periphery of this clutch spider is grooved to give cushioning grip to the leather friction surfaces, and this grooving also further reduces the weight. The edges are spun up or outwards over the leather so that neither centripetal force nor gravity can cause oil to get on the leather or between the clutch surfaces, the belt pulleys also being so constructed as to carry any oil outward and away from the frictions.

Operation is as follows: Slight pressure on the cutting end of the tap applied by the edge of the hole to be tapped, will cause the spider friction to engage that of the forward drive pulley (at the extreme left in the cut), softly and surely, but with sufficient force to drive the largest tap through the toughest material within the capacity of the machine. When the proper depth is reached and the longitudinal action of the work is stopped, the friction instantly disengages, and the spider with tapping spindle comes to a stop, and slight backward pull on the work engages the reverse drive pulley and clutch (at the right above) just as softly and surely and without shock or undue strain.

Oil cups in the pillar clamps contain and feed oil by suction caused by centripetal action, and by gravity through channels and grooves, to every moving part, insuring ample lubrication. The capacity and location of these channels and grooves are proportioned and positioned to prevent undue waste or spattering of the oil.

On the right, the work carrying head is slidably mounted on the bed to accommodate large or small work and long or short taps. The work is carried in a simple fixture with a taper shank which fits into the sliding work spindle, and is further prevented from turning in the work spindle, by a pin slipping into the notch, shown at the end of the spindle. This spindle is light, being hollow and is prevented from rotating by means of an adjustable clamp dog carrying a hardened steel stud upon which rotates a roller with an intermediate slip bushing to reduce friction. These parts are carefully hardened and ground and work in a hardened and ground channel piece, thus preventing rotation, but permitting lengthwise motion without the retarding friction, or the "drag" of a key when under rotative pressure. This reduces the frictional resistance to the forward or backward movement of the tap to a minimum. Rough adjustments for the size of work, length of the tap and depth of tapping, are made by adjusting the whole work carrying head lengthwise on the bed and by adjusting the clamp dog on the spindle.

Fine adjustment for exact depth is made by the finely threaded hardened steel adjusting screw which is tapped

VIEW OF TAPPING MACHINE SHOWING BREAST OPERATED WORK HOLDER.

into the clamp dog and which abuts against a hardened steel stop or button in the tail stock castings, when the correct depth is reached.

SAFETY VALVE SPRING QUERY

Question.—Please give a formula for finding the size of spring for a safety valve, either round or square steel used.

Answer.—The British Board of Trade rules for spiral springs for safety valve springs are:

$$D = \frac{d^3 \times C}{S}$$

$$d = \sqrt[3]{\frac{S \times D}{C}}$$

$$S = \frac{C \times d^3}{D}$$

where D = diameter from centre to centre of wire in inches (without load).

d = diameter of wire or side of square in inches.

S = load on spring in pounds.

C = 11,000 for square steel spring.

C = 8,000 for round steel spring.

Assuming a valve diameter of 3¾ in. to blow off at 200 lbs. pressure and a spring diameter of 3 in. centre to centre, then the load S would be equal to area of 3¾ in. dia. valve multiplied by 200, i.e., $11 \times 200 = 2200 = S$.

The diameter of wire for spring then is

$$d = \sqrt[3]{\frac{2200 \times 3}{8000}} = \sqrt[3]{\frac{6600}{8000}} = \sqrt[3]{.825} = \text{15-16 in.}$$

* * *

Father's Grace.—War economy has evidently made its need felt in the vicarage as well as in the private house. A clergyman's little son went to stay at a friend's house. The next morning he was asked to say grace. As he hesitated, his host, endeavouring to help, said—"Say what father says before breakfast." Thus encouraged, the boy began —"Go easy with the bacon, folks, it's eighteen pence a pound!"

ACTIVITIES OF IMPERIAL MUNITIONS BOARD TO INCLUDE SHIPBUILDING

JUDGING from the continually expanding and variety-nature activities of what is known as the Imperial Munitions Board, with headquarters at Ottawa, it is quite apparent that not only was the establishment of such a body necessary and desirable, but its individual constituent has been such from a business administrative point of view as to earn the confidence and commendation alike of those whom it serves and the specific enterprise it directs. Its activities in munitions production, have, we make bold to say, had to be piloted into channels of effort little anticipated at its initiation, yet, notwithstanding that a number of quite gigantic undertakings relative to increased shell output have been little more than started, we find the Board's attention being given to the no less urgent call for ships, and preliminary steps being taken whereby Canadian shipbuilding and marine engineering enterprise will find the very widest scope outlet.

The twin industry of shipbuilding and marine engineering—aside from their being taken under the wing of the Imperial Munitions Board, is deserving of more than ordinary attention at this juncture, furnishing as it does the certainty of being the medium whereby the cessation of munitions-making will be minimized in acuteness as regards our metal-working plant operations. Evidences are not wanting that gigantic in proportions as shell-making has actually become, there is no reason to believe otherwise than that the industries of shipbuilding and marine engineering, along with their associated trades and craft may actually transcend the other, and what is doubtless of greatest moment, will have a permanent value as a national asset.

It is officially confirmed, we understand, that the Imperial Munitions Board, with whom negotiations have been in progress for some time past by the executive authorities in Britain, are developing an extensive shipbuilding programme to be filled in Canada, the individual details of which will not only tax the capacity of our already equipped plants, but will necessitate their extension, and the creation of further similar establishments. It is well-known, of course, that there exists meantime a very abnormal dearth of shipping—freight or tramp vessels in particular, and that while Germany's submarine activity—curtailed though it be to a great extent, continues, a lessening total tonnage available may be expected.

Notwithstanding the resumption of shipbuilding in Great Britain on a quite generous scale, our losses, both in ships and tonnage, have been enormous; the latter circumstance, however, but serves to demonstrate the fact of our being able to stand the losses, and yet prevail as overseas carriers. There is, nevertheless, a limit to which everything can be strained, individual or national, there is, therefore, wisdom in foreseeing the breaking point well in advance of the latter being reached. At a stage well removed from any real crippling of Britain's merchant fleet, a plan of campaign has been launched, to participate in which—as in men, munitions and money, Canada is invited. James J. Esplen, representative of Britain's Controller of Shipping, is co-operating with the Imperial Munitions Board relative to the placing of vessel contracts and their machinery—propelling and otherwise, while at the same time completing negotiations for the transfer of steel vessels building in Canadian shipyards to foreign order. Progress, we understand, can be reported in both directions.

In recent weeks, not a few corporations have been organized for the specific purpose of constructing steel ships, ranging all the way from 150-footers up to vessels of 7,000 tons, the plant locations covering the coasts of British Columbia, New Brunswick and Nova Scotia. That all of them will find the necessary capital and excellent opportunity for reasonable returns from its investment, may readily be taken for granted. The benefits derivable from the establishment and development of shipbuilding and marine engineering in Canada, of a scope and extent hitherto unknown, have been dealt with in these columns on several occasions, recent and otherwise. The myriad crafts and callings incidental and accessory to each primary enterprise have also been featured. The "way out" from a business depression immediately following the cessation of hostilities is being brought under our observation, in which connection it may not be inadvisable to indicate that there is here a field of productive effort for many of our small engineering concerns now engaged wholly on munitions production. Shipbuilding and marine engineering as exemplified in the finished product—either the combination passenger and freight vessel, or the "tramp," creates opportunity for the manufacture of ship deck machinery, consisting of winches, capstans, windlasses, steering engines, steering gear (hand), etc.; also engine room auxiliaries, which include, pumps, air, feed and circulating; dynamo-engines or ship lighting sets, stop valves, throttle valves, safety valves, sea chests, condensers, piping, lubricators, ash hoists, forced draught and ventilating fans, refrigerating machinery, etc. These, to name but a few of the more prominent accessories of a well-found ship, will serve to indicate a variety of direction in which metal-working plant effort meantime being devoted to shell production may find a waiting opportunity to be taken advantage of.

No apology is necessary for giving special and continued prominence to the matter of Canadian shipbuilding in these columns, feeling as we do that, largely dependent on the attitude we adopt towards it and the nature and intensity of the energy we display to make its outcome worth while, Imperially and nationally, will the business dislocation immediately following the war be nullified.

The General Market Condition and Tendency

PRICES of iron and steel continue very firm, with an upward tendency. Notwithstanding the prevailing high level of prices, further advances on bars, plates and shapes, in the near future, are certain. The expectation of war between the United States and Germany is believed to be the cause of the recent sharp advance in steel products in the American market. In the event of active participation in the war, the U.S. Government would doubtless pre-empt a large tonnage of steel, thus making the situation in the steel trade tighter than ever. This condition would be reflected in the Canadian market by a general rise in prices of steel. The situation in the domestic steel market cannot be said to have improved materially as yet in regard to the fuel supplies. Although receipts of coal, coke and pig iron show some improvement, supplies are not in sufficiently large volume as is required to keep the steel plants operating at or even near capacity. Production of steel during February was seriously curtailed, while the output this month, although perhaps heavier than last month, will be considerably less than at one time anticipated. Foundries are in a better position than they were a few weeks ago, being now able to obtain more pig-iron and coke. The pig-iron market continues very firm and prices are still going up. There is no domestic pig-iron to be had in the meantime, although there may be in the course of two or three weeks. The scrap metal market continues firm, and prices have advanced on some grades of scrap copper, brass, lead and steel. Stocks of cast iron scrap are low, as a result of a big demand, due to the shortage of pig-iron. Prices of all metals are firm, the market, however, is quiet, and business slow. Copper has made a further advance, otherwise prices are unchanged. The machine tool market is quiet, the demand being comparatively light.

Montreal, Que., March 12, 1917.—No marked improvements has been shown in the general situation. Railroad facilities are still taxed to the utmost endeavoring to relieve the congested condition at many points. Good weather is assisting in this matter, but permanent relief is not expected until navigation is opened. The feature of the week is another upward movement in iron and steel prices. The United States crisis is still delayed, resulting in a continuance of anxiety that has been so pronounced for several weeks.

Pig Iron

The heavy demands for foundry iron, together with the higher cost and scarcity of raw materials, has again been reflected in the higher quotations for the various grades of United States iron. These advances range from $1 to $6 per ton, the latter being on Pittsburg foundry, the price asked being $36.95 per ton. Canadian irons are conspicuous by their absence, all quotations being still withheld.

Steel

An undercurrent of additional strength seems to feature the steel situation. This is largely due to the possibility, in the near future, of the United States Government coming into the field on a war-buying basis. The probable result of this action would increase the difficulty, that is at present so pronounced, of Canadian consumers getting supplies from United States mills. Anticipating this contingency, producers in this country are making every effort to offset a scarcity of steel that would handicap the industries at present engaged in munitions and other lines of activity. Higher prices are the feature of the New York market, and further advances are looked for. Furnaces are better supplied with necessary materials, and production is again returning to maximum capacity, but the higher price of coke is reflected. Billets and sheet bars are very firm, and delivery is better. The expected advance on rails has materialized, this week's quotation being $55 and $56 per ton Pittsburg, an advance of $5 per ton. Activity on the part of implement manufacturers, together with the crowded condition of the mills, has resulted in a further advance on iron and steel bars, the Pittsburg quotation being 3½c per lb. No cessation is evident in the abnormal demand for plates, and mills are unable to accept orders under middle of 1918 delivery. This condition has added strength to a very strong market, and an advance of $20 per ton has been placed on the Pittsburg quotation of tank plates, the present nominal price being 6c per lb. Structural shapes and grooved steel skelp have been advanced $7 and $15 a ton respectively. Manufactured steel, including wrought iron pipe and boiler tubes, show an advance, the discount having been reduced two points on W.I. pipe, and on iron tubes 9 points.

The expected advance on wire products has been announced, amounting to $4 per ton. One-half cent per lb. has been added to proof-coil chain quotations. While dealers here anticipate an early revision of prices, no changes are effective this week.

Metals

The metal situation is still influenced by the submarine menace, but the trade is becoming less anxious as to the future. Transportation difficulties have been partly removed, but freight is still congested. Copper is steady, but with a variable tendency. Tin is firm, with a strong undertone. Spelter is firm, but inactive. Lead has become stronger, and antimony is firm.

Copper.—While quotations are of a variable nature, the general market is comparatively free of feature incidents. Consumers are still influenced by the uncertainty of future conditions, and are only covering their requirements for immediate needs. Reports are abroad that negotiations are on for heavy third-quarter export business, but no confirmation of this is at present available. With the end of the war still in the far distance, there is little likelihood that prices will show any appreciable decline for a long period. London markets are a little easier, but the situation in New York is firm, with a slight advance on electrolytic of ½c, and a decline of ¼c on castings. The demand locally is quite brisk, and dealers here are quoting as high as 43c for lake and electrolytic, and 40c for castings, this being an advance of 3c on the former and 1c on the latter.

Tin.—Despite the fact that shipments of tin are daily exposed to the risk of submarine attack, the steady arrival of metal has somewhat restored the confidence of the market, and quotations are generally firm, but strong. However, with the possibilities of loss ever present the situation is marked with a certain degree of nervousness, which would develop into an active upward movement on the sinking of tonnage in transit. Tin is higher both in London and New York, the latter quoting 54c, an advance on the week of one cent per pound. Tin locally has advanced 2c on a steady market, the nominal quotation being 53c per lb.

Spelter.—The market is steady but inactive. In maintaining the present prices, producers are governed by the high cost of ore and in order to secure a fair percentage of profit, some producers insist that spelter should be higher. Spelter is quiet both in London and New York. Local conditions are unchanged, with prices steady at 15c per lb.

Lead.—Independents have again advanced their quotations the nominal price of 11c representing an advance of ¼ cent per lb. Dealers here continue to quote 12½c on a firm market.

Antimony.—Slight activity is noted in futures, but spot metal is quiet. Improved railroad conditions have given relief but the market is generally firm. The situation here is unchanged and firm at 34c per lb.

Aluminum.—The market is very firm. The quotation of 70c is steady and strong.

Machine Tools and Supplies

No feature has developed to change the general situation, and the market continues to reflect the uncertainty prevalent in industrial circles, regarding the early future of all lines of activity. The attitude of the United States government, respecting their decision on the marine policy, has disturbed the general conditions and the trade is awaiting developments. Delivery has improved but is still unsatisfactory. Activity is expected to increase as the spring opens up and the time draws nearer for the placing of additional shell contracts. The further advance of raw materials may result in higher prices in machine tools and accessories.

Scrap

Satisfactory conditions prevail in all lines of scrap. Business is brisk and the volume is quite large. Dealers are taking advantage of the high price of lead and old stock is being unloaded. All classes of old material are very strong on the New York market and the movement is one to higher levels, the exception being in old zinc which is easier. Local changes are confined to coppers and brass, although all metals are quite active. Old copper has advanced 1 cent per lb., the quotation ranging from 24c for light to 28c for heavy scrap. Brass clippings and turnings are ½ cent higher, the respective quotations being 18½ and 15½c per lb.

Toronto, Ont., March 13.—Trade continues to be remarkably good although manufacturers are still feeling the effects of the scarcity of raw materials. The freight situation while improving is still causing much inconvenience, and shipments are not coming through as quickly as they should be. Locally the fuel shortage has been relieved to a great extent, but some districts are still unable to get sufficient supplies of coal. The Algoma Steel Corporation may have to close down their plant at the Soo on account of the shortage of coal unless conditions change very materially.

Steel

In spite of the fact that steel prices are considerably higher than they ever have been in the history of the industry, the crest does not by any means appear to have been reached. All indications point to further advances on all iron and steel products, which will be intensified if the United States are drawn into the war, an event which appears highly probable at the present time. Such a climax would result in a heavier demand for steel, and coming at a time when the mills are sold-up for practically the whole of this year, and on some products for longer periods, cannot help but strengthen the situation and possibly lead to a steel famine. That prices on plates and shapes will advance in the near future is practically assured, as the Carnegie Steel Co. has advanced its prices on bars and shapes $7, and on plates by $15 per ton. Seamless and lapweld tubes are certain to advance owing to the sold-up condition of the mills. Some makers are sold-up for this year and have also considerable business booked for 1918. Heavy premiums are being paid for fairly prompt shipment of either iron or steel tubes. The demand for ship plates and sections is extremely heavy, being only limited by the ability of the mills to roll the material. The mills are quite unable to cope with the demand for plates coming in from all quarters. The situation is unprecedented, and prices will likely reach a much higher level than now obtains. Prices of wrought pipe have advanced.

Prices of sheets continue very firm with demand for exceeding the supply. Prices are much firmer and further advances are looked for. The railway situation is improving but production is still below capacity. Sheet bars are more readily obtainable but are still higher in price. A further advance in galvanized sheets is also likely.

The steel market in the United States continues very strong and there is every indication of prices going still higher. The advance in bars, plates and shapes, referred to above, indicates the trend of the market generally, and is believed to have been prompted by an expectation of heavy buying by the U.S. Government. The decline in the output of steel in February, which averaged 96,000 tons per day, and was the lowest since August 1915, has not improved the situation. The unfilled orders of the U.S. Steel Corporation on February 28 were 11,576,697 tons, an increase of 102,643 tons over the preceding month. This constitutes a record.

Pig Iron

The situation in the pig iron market is slowly improving on account of the more favorable weather conditions and better transportation facilities. Foundries will now be able to get supplies of coke and pig iron and thus extend operations. Domestic foundry irons are still off the market, and no quotations can be obtained. The pig iron market in the U.S. is firmer and prices on some grades have advanced. Production is increasing and coke prices are easier.

Scrap

The market continues strong, and higher prices on some old materials have been registered. The shortage of pig iron which has existed for some weeks has caused foundries to take more scrap than usual, with the result that dealers' stocks of cast iron scrap have been almost cleaned up. There has also been a heavier demand for steel scrap resulting in an advance in prices of heavy melting steel and old rails. Some grades of copper scrap have also advanced while heavy lead and scrap zinc are higher. The following new prices are now in affect. Heavy copper 27½c; copper wire, 28c; No. 1, machine composition, 23c; No. 1 brass turnings 17c; heavy lead 10c, and scrap zinc 10c per pound, heavy melting steel $16; No. 1 machine cast iron $10; and steel rails $18 per ton.

Machine Tools

There have been no developments of importance to note in the machine tool market, business for the most part consists of orders for single tools for munitions plants.

Supplies

Prices of machine shop and mill supplies continues to advance, with business brisk. American makers of lathe chucks have advanced their prices, new discount being list plus 50 per cent., as against list plus 30 per cent. formerly. A further advance of approximately 10 per cent. has been made in the price of globe, angle and check valves. Standard lines now carry a discount of 15 per cent. high grade 10 per cent., and medium pressure 40 per cent.

Metals

The situation in the metal market has not changed much during the past week. Owing to the unsettled outlook, business is dull, any pronounced activity is not looked for until the political situation clears up. That is to say, if war were declared between the United States and Germany, it would relieve the present tension and an active market would result. The feature of the market is the continued advance in copper which has touched a new high level. Quotations on other metals are unchanged but firm. Business locally is very good but a scarcity of copper is reported.

Copper.—The copper situation shows very little change although the price has advanced and is still nominal. The metal is very scarce for all deliveries over the first half, but the demand continues light and the market quiet. The position of copper will be a strong one while the war lasts, and there is no indication at present of any recession in price. Copper has advanced 1c and is quoted at 40c per pound for lake and electrolytic, and 39c for castings copper.

Tin.—The market is quieter but prices continue firm and unchanged. The market is still being affected by the submarine menace, but not so much as formerly. Supplies of tin continue to come across in steady volume but the demand is small. Local quotations 56c per pound.

Spelter.—The situation in the spelter market is unchanged and the price stationary. The demand is light and market quiet. Local price 14c per pound.

Lead.—The market is well sold ahead, there being very little lead left for March or April delivery. The market continues strong and prices unchanged at 12½c per pound.

Antimony.—There is still some scarcity of antimony but the market is easier and unchanged at 35c per pound.

Aluminum.—The demand for aluminum has improved but supplies are lower. The market is firm and unchanged at 68c per pound.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

SAWMILL MACHINERY WANTED IN RUSSIA.

THE Canadian Trade Commissioner in Russia has written an interesting report to the Department of Trade and Commerce at Ottawa, drawing attention to the prospective openings for mill equipment and supplies for Canadian manufacturers in the northerly districts of Russia. He says: "The forest wealth of northern Russia constitutes one of the greatest undeveloped assets of the Empire. In the Governments of Archangel, Vologda, Olonetz, Viatsk and Tobolsk there are some ninety million dessiatines (243 million acres) of almost untouched forests of commercial timber, exploitation of which has become now an economic necessity dictated by the need of improving the balance of trade in Russia's favor and of raising the value of the rouble.

"Conferences have taken place recently between the Secretary of State for Domains and all the northern timber exporting firms and sawmill proprietors, for the purpose of concerting measures for a program of development calculated to secure satisfactory results, and which at the same time will insure the opening up of these northern districts. It is assumed that a market for the timber will be found in the allied countries, chiefly for the rebuilding of the devastated districts of Belgium and France, and to a less extent, in the United Kingdom.

Twenty Million Logs Annually

"The Domains Ministry estimates the possibility of obtaining an annual cut of twenty million logs, or approximately one million standards of sawn goods. It seems doubtful whether the present means of production in the regions in question are capable of dealing immediately with so large an annual cut. An enlargement of the existing mills, and the creation of new sawmills will be necessary, as well as the establishment of other industrial concerns using wood as their raw material for the manufacture of mechanical and chemical wood pulp, paper wooden ware, matches, sashes and doors, moulding, etc. It is regarded as essential for the end in view, that as little as possible of Russian timber should be exported in an unmanufactured state.

Resolutions Passed by Conference.

"A number of resolutions were adopted by the conference regarding the opinion that the estimate of twenty million logs could be handled by Russian capital and Russian labor, and that the granting of concessions to foreigners should not take place; that a new federation or syndicate comprising all the timber exporters in northern Russia be created, to whose members small concessions be made, the terms of such concessions to run from three to twelve years for the production of sawn goods, and up to thirty-six years for the production of pulp. In the latter case suitable districts to be selected and waterpower to be given free; that all logs sold from the Government forests be sold exclusively to the new federation, which would itself take over the direct sales to the representatives of the Allied Governments, and that no Government monopoly be created; that members of the federation be entitled to import duty free the machinery and materials required for the extension of existing mills and for the creation of new ones; that employees be treated as working for the defence of the State and therefore not to be called up for military service.

Where Canada's Interest Lies.

"Canada's interest in these proposals will be solely in the ability of her manufacturers to participate in the supply of the sawmill machinery equipment, woodworking machine tools as well as the mill and factory supplies that will be required, all of which may be said to be our particular specialties. There will be openings also in other directions, as the development contemplated will call for much contracting work, as well as machinery for widening and deepening canals, for river improvements, the provision of a large complement of tugs and barges and for general supplies of great variety.

There Will be Competition.

"It need hardly be emphasized that in connection with such openings the personal investigation by Canadian manu-

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—H. R. Pousaette, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H Ross, Stock Exchange Building, Melbourne. Cable address. Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—Acting Trade Commissioner, Lonja del Commercio, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—G. B. Johnson, P. O. Box 109, Yokohoma. Cable address. Canadian.

HOLLAND—Acting Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address. Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrivskaya, Ploshch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent. Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address. Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address. Cantracom.

UNITED KINGDOM—Harrison Watson, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street. Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 27-28 Pearl Building, East Paradise, Leeds. Cable address. Canadian. F. A. C. Bickerdike, Canada Chambers, 36 Spring Gardens, Manchester. Cable address. Cantracom. J. T. Lithgow, 87 Union Street, Glasgow, Scotland. Cable address. Contracom.

SPECIAL TRADE COMMISSIONER—LUMBER

H. R. McMillan, visiting Europe, Africa, Australasia and the Orient.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin, Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address. Canadian. R. H. Curry, Nassau. Bahamas.

NORWAY AND DENMARK—C. E. Sontum Grubbeged No. 4, Christiania, Norway. Cable address. Sontums.

CANADIAN HIGH COMMISSIONER'S OFFICE

UNITED KINGDOM—W. L. Griffith. Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion. London.

facturers or of their expert representatives is indispensable, if practical results are to follow. Probably the opening of a bureau of information on joint account in Petrograd for dealing with such matters would meet the situation most effectively. The present occasion, for instance, would provide the opportunity for introducing the most up-to-date methods of Canadian sawmill practice, especially the use of band-saw machinery as against the reciprocating frame saw for dealing with the large size timber of these virgin forests; inquiry into questions relating to financial and exchange matters, credit terms and Russian business methods generally. All these matters can only be studied and considered adequately by personal contact with the interests concerned and it is only upon their proper settlement that the foundation of broad and permanent trade relations can be established between the two countries. The Russian responds very readily to new methods which have proved their usefulness in countries like Canada, where the conditions and climate so closely resemble his own. In the past Norway and Sweden have supplied much of the equipment of Russian and countries will undoubtedly be our keen Finnish timber industries, and these competitors in the future, but there should be room for all."

SUBMARINE MENACE BEING COMBATED

OFFICIAL figures from the British Admiralty, made public in New York, a few days ago at the office of the Consul-General of Great Britain, show that during February 94 British merchant ships were destroyed by mines or submarines. Of this number, 61 ships were of 1,600 tons or over. In addition to merchant ships, 29 fishing vessels of British register were sunk. During the month, and up to March 4, 67 British merchant vessels were unsuccessfully attacked by submarines. The number of merchant vessels of all nationalities, over 100 tons each and exclusive of local or fishing craft, which arrived at and departed from British ports were as follows: Arrived, 9,463; sailed, 9,124; total, 18,587. More than 2,000,000 tons of shipping is now on the stocks in various shipyards, all in more or less advanced stages of construction. "The general situation," the Admiralty announced, "is considered quite satisfactory."

Trade Inquiries

THE Department of Trade and Commerce, Ottawa has received the following enquiries:—

545. Engineers' Tools.—An old-established engineering firm in Barbadoes makes inquiry for Canadian tools.

548. French Agency.—A French civil engineer in Paris desires to secure agencies from Canadian manufactururers of steel, electrical motors, machine tools, machinery and general supplies for factories.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Montreal, Que.,—The Stowell Screw Co. will build a factory at Longueuil.

Hamilton, Ont.—The Dominion Steel Foundry, Ltd., will build an addition to their plant, to cost $27,000.

Shawinigan Falls, Que.—The Belgo-Canadian Pulp and Paper Co. are building an addition to their mill here.

Montreal, Que.,—The Montreal Locomotive Co. will extend their plant. Four separate buildings will be erected at a total cost of $5,900.

St. John, N.B.—The C. P. R. propose erecting a 40,000-gallon steel water tank at Bay Shore. A new 60,000-gallon steel water tank will be set up at Jackman, Maine, and a 40,000-gallon vessel will be provided at Holyoke, Maine.

Three Rivers, Que.—The Mechanical Engineering Co., of Montreal, are building a new factory here, to cost about $100,000. The plans include a large machine shop, which will be equipped with new machinery.

Brantford, Ont.—Mickle, Dyment & Son have entered the toy industry and have completed a shipment to Toronto of a carload of new wooden construction model sets. Two local firms are now ousting imported toys from the Canadian market, and preparing for the time when German products will again come into the market.

Halifax, N.S.—Development of the water-power of the Gaspereau River is not to be undertaken, for the present at least, by the Nova Scotia Tramways & Power Co. The tidal forces at Cape Split or the development of hydro-electric powers elsewhere are to be awaited before expenditures are made on the Gaspereau proposition.

Haileybury, Ont.—The big power development scheme being under construction at Gowganda by the South Bay Power Co. is now under way. The construction of a dam six hundred feet long at Hanging Stone Falls is to be rushed and completed before the spring break-up. One initial unit with a capacity of five hundred horsepower will be installed.

MUNICIPAL

St. Thomas, Ont.—The Town Council contemplate installing a sewage disposal plant.

Swift Current, Sask.,—The City Council contemplate purchasing a 615 h. p. oil engine.

Montreal, Que.—Nineteen tenders have been submitted to the Board of Control for the supply of ten motor sprinklers and the same number of sweepers, which the city plans to buy. The prices ranged from $5,500 to $9,700 per machine.

Winnipeg, Man.—Over $12,000 is to be spent on repairs and improvements to city incinerators used in the destruction of garbage and other refuse. W. P. Brereton, city engineer, reported to the Board of Control that to instal the new pre-heater at Elgin Avenue would cost $5,750. The concrete chimney, to replace that recently taken down at Elmwood incinerator, is expected to cost $6,500.

Toronto, Ont.—Mr. Proctor, assistant to Engineer James, has submitted a report to the Etobicoke Township Council relative to the Islington, Lambton and Long Branch water scheme. With regard to Long Branch, it is proposed to bring water from New Toronto, necessitating the installation of new mains from that municipality. No action was taken by the council. The engineer will submit the details and estimates of the proposition to the ratepayers in the near future.

ELECTRICAL

Montreal, Que.,—The Montreal Tramways Co., are building a sub-station on Cote Street.

Brockville, Ont.—The Hydro-Electric Commission will prepare new plans with reference to Brockville, and these are to be submitted in two weeks for the examination of the Public Utilities Commission of the town.

GENERAL

Woodstock, Ont.,—The Harvey Knitting Co. will build an extension to their factory here.

Goderich, Ont.—The Doty Co. plant will be taken over by W. H. Hutchinson, of St. Catharines, and R. A. Pringle, of Ottawa.

London, Ont.—The City Council have granted the McClary Mfg. Co. permission to lay a gas main to the city limits to connect with the Southern Counties Gas Co.'s line.

Windsor, Ont.—It was announced here that Brener Brothers, of London, one of the largest manufacturers of cigars in Western Ontario, will shortly begin the erection of a five-storey building in this city, to be used by them as a factory. The building will cost $75,000, and will be located at London street and Dougall avenue.

TENDERS

London, Ont.—The County Council of Middlesex are in the market for a 10-ton steam road roller. Tenders received until March 22. John Stuart, county clerk.

Toronto, Ont.—Tenders, addressed to the chairman of the Toronto Electric Commissioners, will be received until March 28 for synchronous condensers. Specifications may be obtained at the office of the purchasing agent, 15 Wilton Avenue, Toronto.

Sherbrooke, Que.,—The City Council is receiving tenders for approximately 7,000 feet of galvanized iron pipe, from ¾-inch to 1¼ inch, together with fittings, valves from ½ inch to 8 inches, 10 tons pig lead, lead wool, packing, etc. Purchasing agent, H. C. King.

Yorkton, Sask.—Tenders are being received for the following: One 357 h.p. oil engine, one 280 k.w. generator, one transformer down to 30 k.w., 450 feet of 4-inch cast iron pipe, 200 pounds of lead. Further particulars from F. J. Pilkington, town clerk.

Toronto, Ont.—Tenders will be received up to April 2, addressed to the chairman of Toronto Harbor Commissioners, 50 Bay Street, Toronto, for the construction of harbor head walls. All information may be obtained by applying to the above address. E. L. Cousins, chief engineer and manager.

Toronto, Ont.—Tenders for Synchronous condensers, addressed to the chairman of the Toronto Electric Commissioners, will be received until March 28. Specifications, form of tender and all information desired may be obtained at the office of the purchasing agent, 15 Wilton Avenue, Toronto.
